On a warm day or in a crowded, heated room, we feel "stuffy" because we one and all load space with water vapor, respiring as well as perspiring; and the thirst of space for water vapor is soon satisfied. Our bodies are heat engines, driven by internal combustion of food; and we readily become heated. If we had indicator gages we could watch the moisture and temperature rise; and just as soon as these passed certain critical values, our feelings of discomfort and irritability would become evident.

It is the effort to adjust ourselves to new requirement which makes us uneasy. We are fighting to keep a balance between heat developed within, heat thrust upon us, and heat expended. It is important to keep warm enough to be comfortable, but equally important to keep cool enough to be comfortable; and this last during the dog days is best accomplished by efficient skin action, and the vaporization of sweat. A dry dog day facilitates this; a damp dog day makes it difficult or even impossible.

## Where Willow Ware Comes From

(*Continued from page 222*)

the spacing recommended by Uncle Sam for purple willow, plants are set 6 by 30, 9 by 30, or 12 by 30 inches.

The first two years is the critical period for the young plants. Where the cuttings are closely spaced, hand hoeing must be practiced as often as necessary to keep the weeds in check while where wide spacing is pursued a horse can be used to perform this work. Cultivation must be thorough but it should never be deeper than 2 to 3 inches. Where cultivation is properly practised and where the spacing of the plants is correct, it is almost impossible for the obnoxious weeds to gain a foothold. Frequent and regular inspection of the willow tract is essential in order that the owner may stamp out and control such pests as morning glory vines, caterpillars and dodder whenever they appear.

It is inadvisable to neglect spots where plants fail as all such places should be replanted the same year in which they develop. Where such spots are neglected for long periods it is very difficult ultimately to set out replants which will live and flourish. Usually the replants should be set out each season after the willows have been cut over at harvest time, in order to give them an early start. The replants should be allowed to grow for two seasons without cutting and then should be cut back to the original size of the second season plants as otherwise they will shade the older, established plants.

Generally, the willow should be cut before the buds begin to swell as late cutting after the growth has started in the spring restricts the output of the succeeding crop, while it also retards the new growth. Willow rods that are to be steam-peeled may be harvested as soon as the leaves fall and the wood has matured. Rods which are to be sap-peeled or used for cuttings should not be removed until December or January unless satisfactory storage facilities are available. Usually, the ordinary hook knife is the best tool for cutting willow rods as where pruners are used it takes from one-third to one-half more time to perform the work. Stools should be cut as low as possible as practical experience has demonstrated that the best longtime results obtain where this method is followed. Under labor conditions which existed previous to the war, the average cost of cutting willow rods ranged from $10 to $15 an acre where the yield did not exceed two to three tons green weight.

As soon as possible after cutting, the rods should be bundled according to size and shape, either binder twine or small willow rods being used. After the leaves appear in the spring, the rods have to be kept in water until peeled as otherwise they die and then it is impossible to remove the bark. For this reason the rods are kept in pits where the water is deep enough to cover the ends of all the rods, the willow crop being kept upright in such pits until time for peeling arrives. The difficulty of securing labor which will properly peel the rods by drawing them between two steel plates or bars which have spring enough to break but which do not crush the wood is often the limiting factor in basket willow culture. The industry would be vastly benefited by the invention of a practical peeling machine which would eliminate this costly hand labor expense.

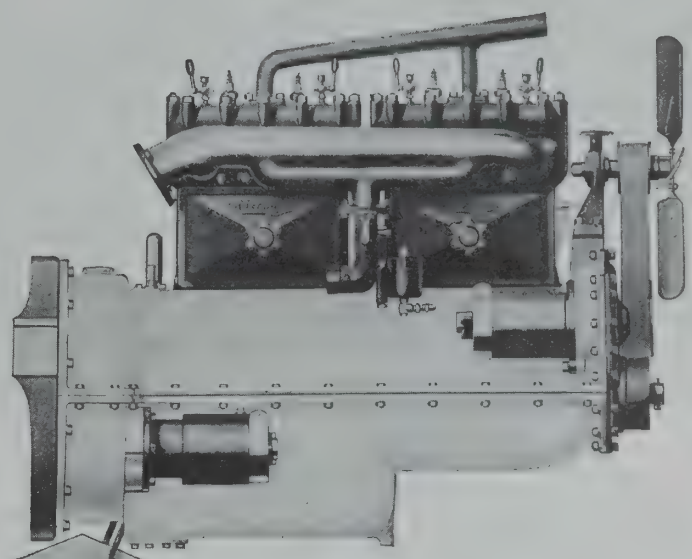
Experts maintain that the fact that most of the American-grown willow is steam-peeled is disadvantageous to the trade in general as it lowers the market quality of the rods and also centralizes the industry in the hands of a few dealers instead of under the control of the small growers and basket makers. After being peeled the rods should be dried thoroughly for one to two days in the hot sun before being bundled. It is necessary to cover them at night and during rainy weather as, otherwise, the rods lose their whiteness. Usually, the preferable time for sorting the rods is during the peeling process.

Ordinarily the income from the basket willow farm does not amount to much until the third year but henceforward up to the fifteenth season the average annual net profit per acre should range from $85 to $100. Abroad, willow baskets are used exclusively, hampers of all grades and quality being made from willow. In America, pine, oak, ash, elm, reed and rattan baskets are on the market in competition with willow to such an extent that a dependable and profitable market exists for only the finest grade of fancy willow baskets. On this account the bulk of the American willow supply is used in the manufacture of furniture.

## The Heavens in September, 1920

(*Continued from page 224*)

be easy to see. Mars is past quadrature, and is an evening star, setting about 9:30 p. m., standard time, in the middle of the month. Jupiter is a morning star, rising from one to two hours before the sun. Saturn is in conjunction with the sun on the 7th, and practically invisible. Uranus is in Aquarius, and is visible all the evening. Neptune is a morning star in Cancer, inconvenient to observe.



Higher Price

-but Lower Cost per Ton-Mile

Automotive engineers who look beyond the price tag will tell you why it pays to specify

Wisconsin CONSISTENT Motors

When cheap engines no longer give service, Wisconsin Motors are still good for hundreds of miles of dependable power. Thus, though the initial cost may be slightly higher, Wisconsin-powered trucks ultimately cost less per ton-mile.

Every Wisconsin Motor is run-in, torn down, inspected and re-adjusted before re-assembled. Each leaves the shop *ready to run.*

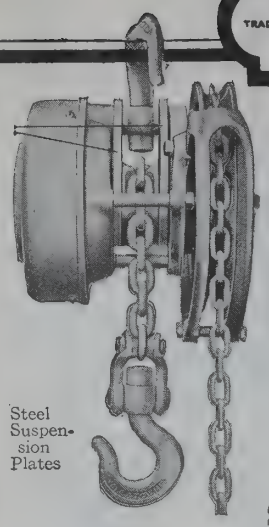
Wisconsin CONSISTENT MOTORS



YALE

## The Block With Safety Built Into It

SOMETIMES your chain block, in its lifting of raw materials, parts, or cases of finished product, will be subjected to severe shocks or overloads.

Ordinary cast suspension members might break under the strain. But the steel suspension plates of the Yale Spur-geared Block safely carry the load.

The economy of the speedy, powerful Yale Chain Block, or Electric Hoist makes it the first choice of the careful buyer.

Yale Chain Blocks are carried in stock by all representative supply houses. Our new Hoist Catalog explains the details. Write for it.

**Williams "Agrippa" Tool Holders**
*"The Holders That Hold"*

THE illustration shows Williams' "Agrippa" Boring-tool Holders which accommodate all shapes and sizes of Bars within their range, without any bushings whatever.

Williams' "Agrippa" Tool Holders are made in a wide range of sizes for all regular machining operations. Briefly, they are the toughest and strongest Tool Holders that excellence of material and workmanship can produce. Like all Williams' *Superior* Drop-Forged Tools they represent the progressive experience of nearly half a century, and when they pass our rigid inspection they are capable of withstanding greater strain than will ever be put upon them.

Send for Machinists' Tools Booklet which gives full details.

## A Forward Step in American Airplane Engines

(*Continued from page 226*)

There are 12 cylinders of 5¾-inch bore and 6½-inch stroke, and 2 banks of 6 cylinders forming a Vee with an included angle of 60°. Two inlet and two exhaust valves are used for each cylinder, each valve port being 2 inches in diameter. Each pair of valves is operated by a duplex rocker arm, working in conjunction with a single cam. Two spark plugs are used per cylinder and thanks to the clean "alley" between the cylinders, are notably accessible, not requiring the use of a special wrench. The ignition current is supplied by an improved battery system which is arranged in duplicate. The distributor heads are fixed in place and the spark advance is obtained with a slidably controlled drive shaft.

The engine complete weighs 1,118 pounds and in its initial test delivered 578 hp. at 1,920 r.p.m. or 1.94 lb. per b.h.p., as against an average of 2 to 2¼ lb. per b.h.p. in the best of the war-time engines. This can be considered a very satisfactory performance in view of the fact that the engine went through its initial test in exactly the condition received from the assembly department and without any modifications. Gasoline consumption was at the rate of .52 lb. per b.h.p. hr. for maximum power carburetor setting and .45 lb. per b.h.p. hr. for maximum economy carburetor setting. Oil consumption was at the rate of .025 lbs. per b.h.p. hr. which also represents a remarkably good economy.

It is evident that an engine of this type has a wide range of usefulness due to its rugged design in combination with comparatively light weight. For use with a flying boat, heavily loaded commercial or war plane, a flying speed of say 80 m.p.h. corresponding to 1,275 to 1,350 r.p.m. of the engine with an output of 400 to 420 hp. could be maintained and this would undoubtedly allow of 250 flying hours without overhauling the engine. If run at somewhat higher speed, say 1,500 r.p.m., the engine is capable of developing about 475 hp. and would be eminently suitable for long distance work at comparatively high speed, say 100 to 120 m.p.h. such as would be required for a bombing plane in war time or a mail plane in peace time. If it was desired to utilize all the power the engine is capable of developing, a light low-resistance plane could be designed around this engine which would have some startling speed possibilities far in excess of anything yet accomplished.

It is to general commercial uses, however, rather than to employment in war or in racing, that I look for the greatest value of this engine. Since America is not and never will be a military nation, aviation cannot hope for adequate development through appropriations for naval or military purposes. Yet until we are in a position to dominate the air above our country in case of emergency, America will not be safe.

The only answer to this problem is the development of commercial aeronautics. I believe that America is now second to none in the matter of engine design, except possibly in air-cooled fixed radials, and though we are not so far advanced in plane design, we can lay claim to having originated most of the ideas used in airplanes today all over the world, and I am convinced that if we can make a business of aeronautics, thus putting it on a sound financial basis, we have the talent and the facilities to lead the world.

## This Year's Nominations for the Hall of Fame

(*Continued from page 226*)

bronze tablet and put up in the corridor of the Hall. If Hunt is elected this year there will be two tablets each crediting a different person with the invention of the sewing machine.

It is claimed that Hunt invented a machine for sewing which was provided with an eye in the point of the needle and a shuttle in 1834-1835, which was more than ten years before Elias Howe obtained a patent for a sewing machine. Among other inventions of Walter Hunt is the paper collar, the safety-pin, a repeating rifle and pistol, a forest saw with lever for cutting and felling trees, an improved kerosene lamp, a fountain pen, an improved stopper for bottles, etc.

The inventors elected to the Hall of Fame in previous elections and whose names are already inscribed on bronze tablets in the Hall are Robert Fulton, inventor of the steamboat; Samuel Finley Breese Morse, inventor of the telegraph; Eli Whitney, inventor of the cotton gin; and Elias Howe, inventor of the sewing machine. Howe was elected in the last election, 1915. The others were all elected in the year 1900 at the first election when the Hall of Fame was built and inaugurated.

The ten scientists whose names appear on the 1920 ballot are Benjamin Thompson, Matthew Fontaine Maury, Benjamin Pierce, Nathaniel Bowditch, Spencer Fullerton Baird, Benjamin Silliman, Josiah Willard Gibbs, Samuel Pierpont Langley, Henry Lewis Morgan, and Simon Newcomb. The four latter are new nominations this year, while the former six have been voted upon in every election since and including 1900.

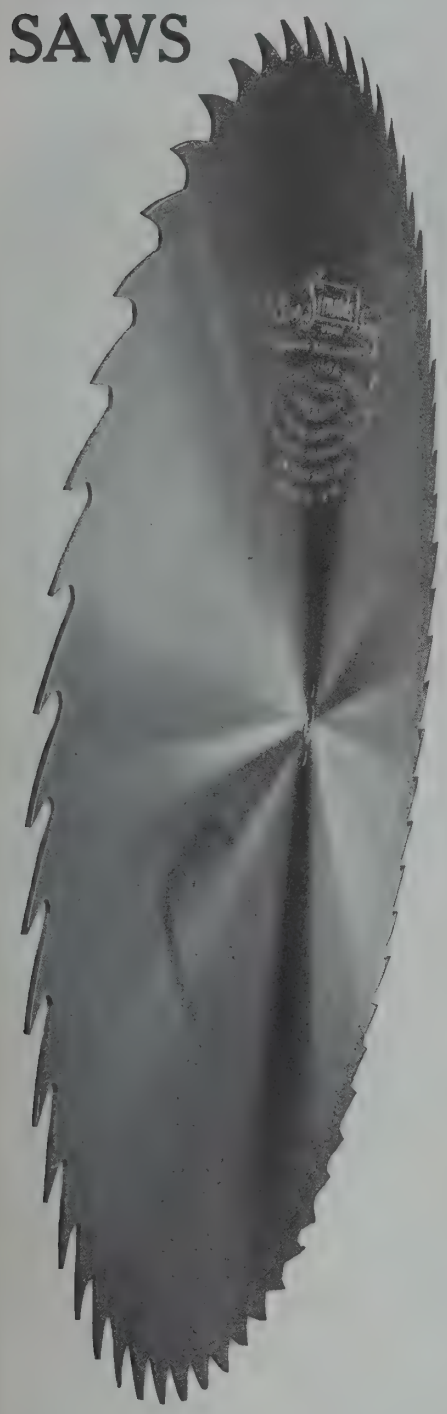
The scientists already elected and whose names are on tablets in the Hall are John James Audubon, Asa Gray, Louis Agassiz and Joseph Henry. The two latter were enrolled in 1915, while Audubon and Gray were elected in 1900.

There are two inventors whose names appear on the ballot this year but not under the classification of Inventors. One is William T. G. Morton, the dentist who invented anaesthesia and an apparatus for its administration. Dr. Morton is on the ballot under the classification of Physicians and Surgeons. He received a large vote in the elections of 1910 and 1915 and it is likely that he will this year be elected. Dr. Morton, of course, properly belongs under the classification of Inventors. The other inventor who, quite properly, appears in the class of Authors, is Thomas Paine, author of "Common Sense," "Rights of Man" and "Age of Reason." Thomas Paine invented the iron bridge, the planing machine, the hollow candle (which is the principle of the modern central draught burner), etc.

The new nominations on the final ballot now in the hands of the 102 electors to the Hall of Fame are the nominations that were selected by the various groups that considered the names submitted on the preliminary ballot about one month ago. Many names were discarded altogether on the preliminary ballot. Only those names which were approved by a majority of the electors in the various classes achieved a position on the final ballot.

The group which passed upon the names of inventors and scientists is com-

# SIMONDS CIRCULAR SAWS



SIMONDS saw plates are flattened when tempered. It's the SIMONDS method of straightening without hammering. A method insuring a saw that will resist heavy crowding and feeding, will cut faster and smoother, and give longer service.

posed of Alexander Graham Bell, Henry Fairfield Osborn, John Burroughs, Dr. William H. Welch, George F. Swain, General George W. Goethals, Charles D. Walcott, Robert S. Woodward, Dr. Charles H. Mayo, Dr. William J. Mayo, and George Ellery Hale.

The 102 electors to the Hall of Fame are persons of distinction in various professions and are located in all sections of the country. These electors are listed in seven groups as follows: Actual or Former University or College Presidents, Historians and Professors of History, Scientists, Authors and Editors, Men and Women of Affairs, Actual or Former High Public Officials, Actual or Former Justices, National or State.

There are "vacancies" in the Hall of Fame to be filled this year by the names of twenty men and ten women—if elected. It is unlikely that more than a dozen men and five women will be given a vote large enough to secure their admission to the Hall.

## Smothering Fire with Bubbles of Gas

*(Continued from page 228)*

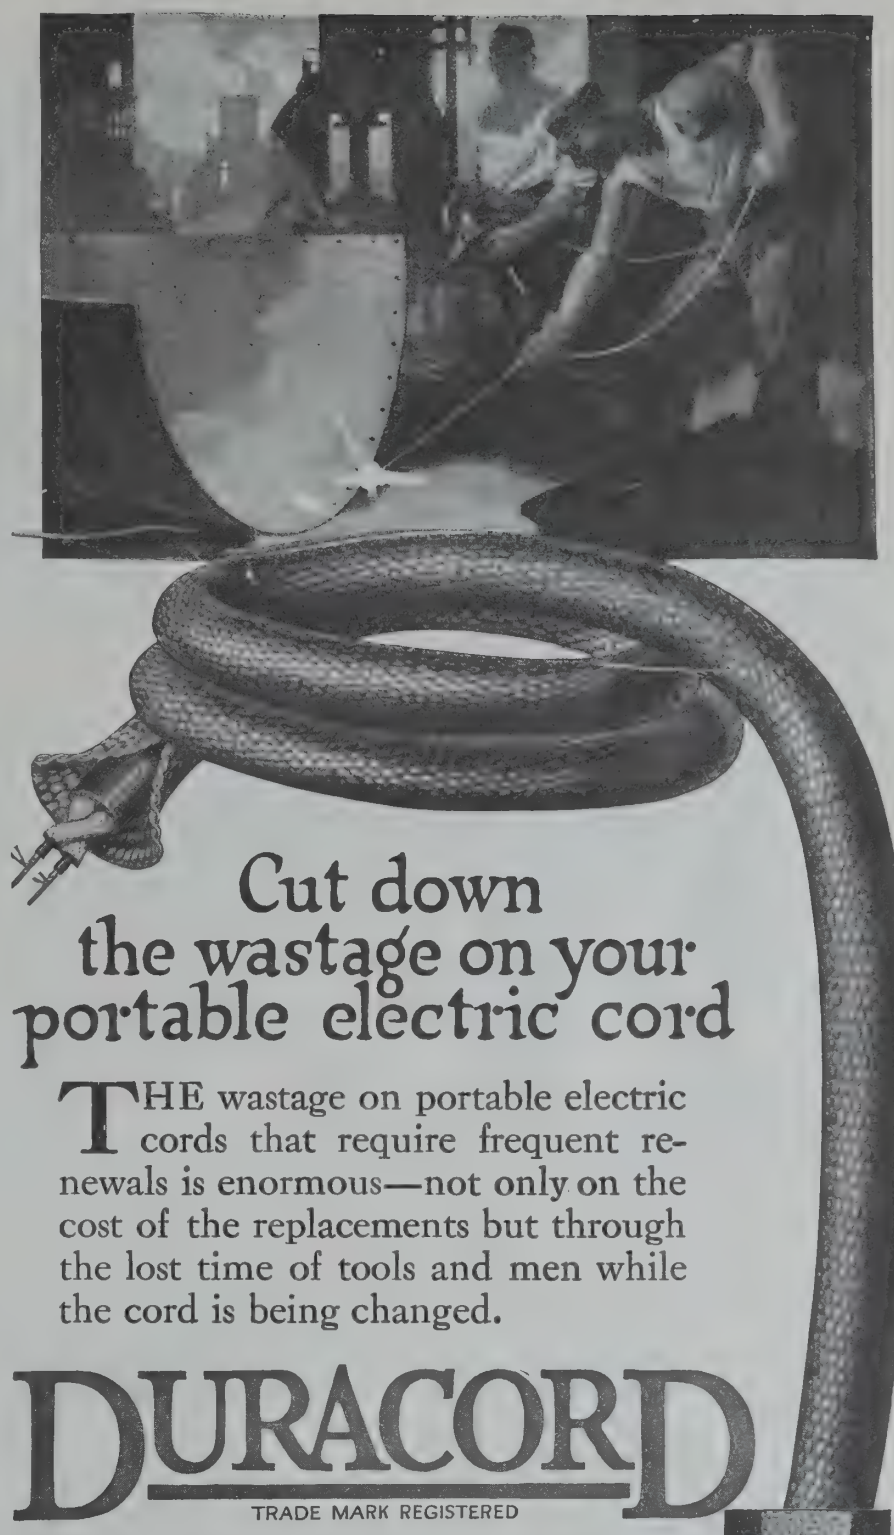
dioxide will naturally have disappeared. There will remain, however, a curious mass distributed over the area which will consist largely of the sodium sulfate and the aluminum hydroxide shown at the right of the equation, or modifications of these.

It is not so long that the world has known exactly what is the thing we call *fire*. But, in 1786, the great Lavoisier revealed the truth in a single sentence: "Fire is the combination of a substance with oxygen." When the suds made as indicated is thrown onto blazing oil, it contains practically nothing that will combine with oxygen. The sodium sulfate, the aluminum hydroxide and the carbon dioxide, all, are chemical combinations already heavily loaded with oxygen. In so far as the oxygen of the air is concerned, the blanket of bubbles cares nothing for it. In so far as the oil is concerned, the bubbles hold on to their oxygen. The result is that the blanket does not feed the flame in any way. It acts principally as a shield, protecting the oil from the atmospheric oxygen.

The manner in which oil tanks are protected is, in general, as follows. The two solutions are separately kept in suitable containers at some suitable central station. Metal tubes are laid along the ground, or buried in it, from the containers to mixing chambers attached to the several oil tanks. These open on the surface of the oil at their upper ends. The solutions are, upon occasion, pumped through a double line of piping extending from the pumping plant to the tank, each solution along its own line. At the mixing chamber, the two mingle. The quick formation of the carbon dioxide at this point is competent to eject the suds as it forms. Where a considerable number of tanks are connected up with one station, the piping may be arranged so as to avoid the installation of a distinct complete double line of pipes for each and every tank. By the use of valves, certain branches may be cut off and others brought in; so that a complete double line will exist for the particular tank on fire.

The volumes of the two solutions required are equal. It is necessary then that the arrangements be such that equal deliveries are made at the mixing chamber. The twin duplex pump or the flywheel pump are approved types for the purpose. It is understood that the ordinary duplex pump is liable to be ineffective because of short-stroking.

The amount of foam or suds required for an oil fire will naturally vary with the character of the conflagration. Usually, a quart of each of the two solutions per square foot of surface will when mixed and converted into suds be competent to



# Cut down the wastage on your portable electric cord

THE wastage on portable electric cords that require frequent renewals is enormous—not only on the cost of the replacements but through the lost time of tools and men while the cord is being changed.

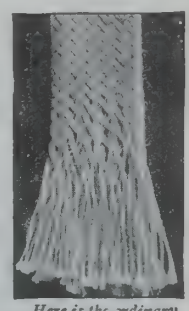
# DURACORD
TRADE MARK REGISTERED

Duracord reduces this wastage to a minimum. The heavy *woven* covering of Duracord is like fire hose. It protects the insulation against abrasion, oil, water and heat—destructive enemies to which every cord is subjected in ordinary service.

Insist on Duracord and get uninterrupted service from your portable electric tools, extension lamps, magnetic cranes, loading or conveying machinery, welders or any of the thousand and one other uses of this quality cord.

Duracord can be furnished in all sizes of portable electric cord and also in the larger sizes of single and duplex cable. Ask your electrical jobber or let us send you samples of Duracord and ordinary cord for you to test and compare yourself.

*This is Duracord. Thick, heavy strands, woven like a piece of fire hose, not braided. Picture shows outside covering only with impregnating compound removed.*



*Here is the ordinary braided cable covering. Note the open and porous construction, easily cut, stretched or unraveled. Compare it with the illustration of Duracord above.*

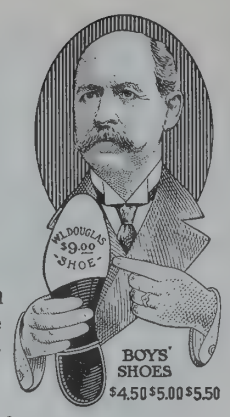
THE SHOE THAT HOLDS ITS SHAPE

**$7.00 $8.00 $9.00 & $10.00 SHOES**

**FOR MEN AND WOMEN**

**YOU CAN SAVE MONEY BY WEARING W. L. DOUGLAS SHOES**



The best known shoes in the world. They are sold in 107 W. L. Douglas stores, direct from the factory to you at only one profit, which guarantees to you the best shoes that can be produced, at the lowest possible cost. W. L. Douglas name and the retail price are stamped on the bottom of all shoes before they leave the factory, which is your protection against unreasonable profits.

W. L. Douglas $9.00 and $10.00 shoes are absolutely the best shoe values for the money in this country. They are made of the best and finest leathers that money can buy. They combine quality, style, workmanship and wearing qualities equal to other makes selling at higher prices. They are the leaders in the fashion centers of America. The stamped price is W. L. Douglas personal guarantee that the shoes are always worth the price paid for them. The prices are the same everywhere; they cost no more in San Francisco than they do in New York.

W. L. Douglas shoes are made by the highest paid, skilled shoemakers, under the direction and supervision of experienced men, all working with an honest determination to make the best shoes for the price that money can buy.

W. L. Douglas shoes are for sale by over 9000 shoe dealers besides our own stores. If your local dealer cannot supply you, take no other make. Order direct from factory. Send for booklet telling how to order shoes by mail, postage free.

CAUTION.—Insist upon having W.L.Douglas shoes. The name and price is plainly stamped on the sole. Be careful to see that it has not been changed or mutilated.

**110 Years of Making Good Brushes**

Replaced foreign brushes in the U.S. in 1812, and became soon the leading manufacturers of Brushes in the United States. Later, and now, the largest manufacturers of Brushes in the world. Excellent quality; infinite variety of all kinds of Brushes.

Send for Illustrated Literature

John L. Whiting-J. J. Adams Co., Boston, U.S.A.

Brush Manufacturers for Over 110 Years and the Largest in the World

put out almost any fire. Often, half this amount will be sufficient. A good sized oil tank having a diameter of 100 feet can be covered with suds in from 5 to 10 minutes, if a proper size of twin duplex pump is employed and the arrangements are otherwise what they should be. Each of the two solutions should be available in amounts of 600 barrels. The pipe lines to the tank should be of the 3-inch size and two mixing chambers should be provided on the tank. Arrangements may be made for discharging the foam from a nozzle.

Naturally, a substance usable for the quick extinction of oil fires may be employed to put out fires in general.

The development of the mechanical apparatus for the quick generation and utilization of fire-suds is an important side of things. Here American genius has played its part, as well as in connection with the perfecting of the process. Mr. O. R. Erwin has been and is one of the leaders in inventive matters. Many of his experiments have been conducted on a considerable scale. Thus, a considerable trench would be flooded with oil and the whole made the means of testing some phase of the practical development of the suds idea. Then there are others whose names have not been brought to the fore, but whose participation in the forward movement has been valuable. The whole development from the first germinal thoughts would seem to fall within a space of about a score of years.

## Latest Patent Decisions

*(Continued from page 229)*

include a successful structure. Claims should cover what the patentee has invented, and nothing more. The plaintiff has failed to establish infringement.—*Whitlock Coil Pipe Co. v. Mayo Radiator Co. U. S. D. C. of Conn.*

**Different Means to One End:**—Suit in equity by Harry B. Ross against Overlin & Jameson. Complainant sues to enjoin infringement of its patent for improvement in motor trucks. Complainant's motor truck is adapted for picking up lumber disposed in piles; and transporting it in and about saw-mill and lumber yards, and depositing it at places of destination. The process is to drive over or straddle a lumber pile, pick it up, or raise it, by means of the motor used for propelling the motor truck, and, thus suspended beneath the frame of the truck, carry the same and deposit it where needed. Defendant Overlin has devised a motor truck of similar construction, designed to perform the same service and has secured a patent, also, on his machine. Complainant alleges infringement. Held, no infringement for, while Overlin's machine lifts, carries and deposits piles of lumber, it does not do so by the same mechanism as the complainant's truck, the lack being a principal horizontal beam, or a compound structure acting as a beam, receiving vertical load, and bearing vertically upon its supports.—*Ross v. East Side Mill & Lumber Co. U. S. D. C. of Oregon.*

**Jurisdiction over Contracts:**—The bill in this issue alleges that the plaintiff was the inventor of a useful invention in steam traps, and that by an instrument in writing he granted unto the defendant company the sole and exclusive right to manufacture and sell the apparatus—that he was to receive $100 within six months and $5 upon each apparatus sold by said company until he had received the sum of $1,800 in royalties. The bill further alleges that the defendants have sold a large number of steam traps covered by the patent, and on which royalties have accrued and have not been paid.

The motion to dismiss the bill must be granted. While there is a diversity of citizenship, the amount involves less than $3,000. The action is one for breach of contract and in no way involves a determination of whether the patent has been infringed. The bill is dismissed, holding as a matter of law, that a suit for accounting for royalties under a contract granting an exclusive license to manufacture a patented device is not one arising under the patent laws, and where the sum involved is less than $3,000, a federal court is without jurisdiction.—*Odell v. F. C. Farnsworth Co. U. S. D. C. of N. Y.*

## Is the Dam Safe?

ENGINEERING literature is replete with examples of failures of structures traceable to inadequate knowledge on the part of the designer relating to the pressure exerted by the earth against these engineering feats. All of which magnifies the tremendous possibilites of this soil-pressure measuring device, and a series of experiments being conducted simultaneously by the U. S. Bureau of Public Roads and the Miami Conservancy District. The study of slumping in these five earth dams assumes this attitude of a wide core in hydraulic dams: Caving of the banks inward; extension of the soft core by the production of movable material in the banks; and, finally a bursting out of the core either causing or caused by a slip of the weakened bank.

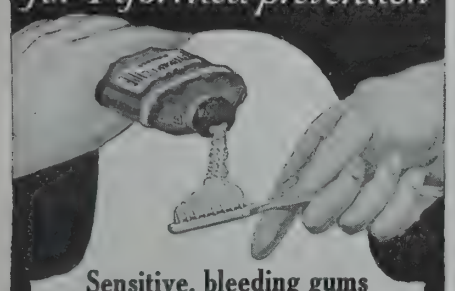
Consequently, in the construction of this quintette of flood-protecting dams the central cores are to be nowhere wider than the final dam height. Such an observance necessitates that the hydraulicing be conducted with a narrow pool, affording an ample section of stable, coarse material on either side. This proves practical if the finest portions in the materials are reduced to a suitably low percentage or if the surface drain from the pool is handled in a fashion to insure the disposition of excess fines. The resulting cone, with side slopes of approximately 1:2, is thought sufficiently wide for compactness and not favorable to induce caving of the bank along the contact. The base width of the core is only slightly in excess of 100 feet in any of the five dams, which is usually less than one-fifth of the dam base. The enlarged width of the outside bank is a source of additional strength.

Percentages of gravel, sand and clay present in the usable material have been determined by investigations, disclosing to engineers the available borrowpits most nearly approaching the requirements for desirable proportions of coarse and fine materials for dam construction. Frequent analyses of core materials are made.

As a precaution of avoiding an excess percentage of fine materials in the core, th mechanical analysis of the pumped material has been so clearly defined as to limit both the percentage of core materials in the total, and the percentage of silt and clay in this fraction. The core percentage is fixed by the cross-section of the dam. Limitation of fines in the core material is determined largely by the results of pressure measurements, as revealed by the soil pressure measuring instruments. The pressure measurements thus far indicate that the material in the cores of these dams is assuming a solid condition.

Resistance to penetration or the supporting power of the cores of the five dams is being determined by lowering a 6-inch cast-iron ball into the pool by a rope, its penetration under weight being recorded. The soil-pressure measuring instrument will doubtless reflect dependable information as to the lateral pressure existing in hydraulic dam cores, and determine the relation of vertical to horizontal pressures. Unpretentious in size and appearance, the device has immense possibilities, and it is not a remote objective for mechanical ingenuity to even outwit what is sometimes considered the fates of floods and misfortune.

# PYORRHOCIDE
**POWDER**
ANTISEPTIC
*for Pyorrhea prevention*



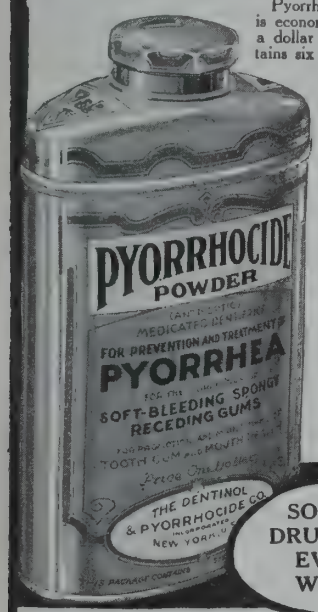
**Sensitive, bleeding gums**

are symptoms of pyorrhea which, if unchecked, lead to the loosening and the loss of teeth.

Pyorrhocide Powder should be used. It is the one dentifrice that dental clinics, devoted exclusively to pyorrhea research and oral prophylaxis, have demonstrated to be most effective in pyorrhea treatment and prevention.

Dentists everywhere prescribe it as an aid in repairing soft, bleeding, spongy, receding gums, and to clean and polish the teeth.

Use Pyorrhocide Powder for firm, healthy gums, and clean, white teeth.



Pyorrhocide Powder is economical because a dollar package contains six months' supply. Sold by leading druggists and dental supply houses.

## Notes and Queries.

**Kindly keep your queries on separate sheets of paper when corresponding about such matters as patents, subscriptions, books, etc. This will greatly facilitate answering your questions, as in many cases they have to be referred to experts. The full name and address should be given on every sheet. No attention will be paid to unsigned queries. Full hints to Correspondents are printed from time to time and will be mailed on request. Please write your queries; do not telephone them, please.**

(14342) C. M. asks: I am writing to ask you for information in regard to insulating magnetism. Is it true that magnetism will penetrate any substance? Can you refer me to a treatise upon the subject? A. Magnetism penetrates nearly all substances with the same ease as it passes through the air. Iron, steel and a few other metals it penetrates with more ease than it penetrates air. It is evident from this statement that magnetism cannot be kept out of substances by ordinary insulation as electricity can be. The only way of insulating a substance from magnetism is to provide an easier path for the magnetism. This is done by surrounding this substance by iron since as we said above magnetism penetrates iron more easily than it does most substances. An iron box will screen its contents from magnetism. The iron should be at least a half inch thick for the best protection. You will find statements on this topic in text books. We do not know any treatise on the subject. It is called permeability.

(14343) H. A. B. asks: I have put up in my yard a sun dial. I got the directions from a copy of the Women's Home Companion, published in Springfield. That article said to find the latitude my place was in, and follow a table they gave, which I did. This place is West Liberty, Ohio, is in latitude 40°. They said to make the "gnomen" that casts the shadow 6 11/16 in. high and see to it that the noon mark, 12 o'clock, is pointed exactly north. Now what I want to ask you is this: If the pointer casts a shadow directly north and south isn't it noon at that place? A. Your question, which seems very simple, is far from actually being a simple question. If a sundial is set correctly so that the gnomon stands exactly north and south the sun at midday will be exactly in the plane of the gnomon and the shadow will fall on 12 of the dial. It is the middle of the time between sunrise and sunset—midday—but not twelve o'clock local time, the true time of your place, except on four days in the year, about April 15, June 14, September 1, and December 24. The dates vary a day or so because of our calendar, in which an extra day is inserted in February in leap years. The difference between the sundial and the local time is called the Equation of Time, of which you should have a table furnished with the dial. Correct the sundial reading for the equation of time and you will have your local time. But your place probably uses central standard time, which is six hours behind Greenwich time, the time of the 90th meridian. To set your clock by the sundial you will require your longitude west of Greenwich. This changed to time gives you your relation to central standard time. Subtract your longitude in time from 6 hours and you have the difference between your local time and central standard time. With these numbers you can set your clock by the sundial reading. Proceed as follows: To the sundial reading add or subtract the equation of time for the day. This gives you your local mean time. To this add the difference between your longitude in time and 6 hours. The result is central standard time, the time to which you will set your clock.

(14344) H. J. S. asks: Scientists and geologists have long stated that as the crusts of the earth cooled earthquakes would become less frequent and in time disappear. The exact reverse of this is now however the case with 468 recorded in 1919. Some of these have been very destructive to life and property and have been scattered throughout the world and are still continuing. Had they occurred during the war it would have been logical to suppose that the huge mine explosions had effected the stability of the strata. Christ said that famines and pestilences and earthquakes in divers places would be signs of His second coming. I do not understand geology so request that you give me a scientific or geological reason for these disturbances

# Sharp? Oh Boy!

THERE'S nothing like these wonderful Durham-Duplex Blades for a cool, safe, satisfying shave. Made from the finest Swedish steel, oil-tempered, hollow-ground and sharpened to an exquisite cutting edge. Extra long and double-edged to give you the greatest shaving mileage. And *guarded* to give you absolute protection when shaving.

# Wire Rope—The Reclaimer

A watery, unhealthful, vermin infested swamp today, the richest farm land a year from today—the result of vision, enterprise, hard work, and the use of hundreds of feet of sturdy, dependable wire rope.

Miles upon miles of the most productive farm land owe their reclamation to wire rope. Operating on dredges and scrapers under most adverse conditions, wet, sandy, dirt incrusted, still they carry on, making it possible to produce valuable crops where disease and crocodiles bred before.

No task seems too great for wire rope—and none too unusual; for the scope of its usefulness broadens every day. But wire rope that is suitable for one purpose is not necessarily suitable for another. Each use makes certain demands upon a rope that must be met in a certain definite way.

The Broderick & Bascom Rope Co. makes wire ropes of different grades and characteristics suitable for all purposes. Each, in its proper place, will give the most service for the least money.

B. & B. Yellow Strand Wire Rope, with one strand of Yellow to distinguish it, has no peer in strength and wearing quality.

and if the formation of North America is such that there would be no danger of quakes away from the western coast. A. The great earthquakes are mostly from one of two causes—the shrinking of the earth due largely to cooling, or the effects of volcanic action. Both of these effects must persist so long as the causes are active. In the long future both causes will cease to be active, and earthquakes must cease. But no scientist would say in years when that time will come. Certainly not in our time. Geology reckons time in thousands and in millions of years, and earthquakes now occur by the thousands each year. It is estimated that there are 30,000 earthquakes a year which are large enough to be perceived by the senses, and an almost innumerable number of lesser tremors which are too small to be perceived. Among these smaller earth tremors would be placed the mine explosions to which you refer. Such an explosion however does not jar the earth for any considerable distance. The great explosion of many tons of high explosives in Hell Gate, New York Harbor, many years ago, was recorded on seismographs for only about 200 miles, a very short distance compared with the distance to which a real earthquake shock is transmitted. Most of our earthquakes are due to the cooling of the earth and the shrinkage of its strata from cooling. The result is the breaking, folding, and slipping of the strata upon each other. A slip of but a short distance will produce a large effect upon buildings and the earth's surface. A motion of a fifth of an inch, it is said, will throw chimneys down. The greater part of the United States seems to be free from violent earthquakes, but in the past there have been great earthquakes in several regions. In 1811-1812 a series was felt in the lower Mississippi Valley, which has been characterized as "of world-shaking order." The last considerable earthquake in the East was the Charleston earthquake in 1886. These facts seem to indicate that severe shocks are not as common as a century and more ago. The great earthquake regions of the earth lie in two circles, one surrounding the Pacific Ocean and the other lying nearly east and west around the earth through the Mediterranean, southern Asia, the East and the West Indies. If you would have a good discussion of this subject we would advise you to get Tarr's College Physiography in which you will find about 100 pages devoted to it.

## NEW BOOKS, ETC.

THE MODEL T FORD CAR. By Victor W. Page, M.S.A.E. New York: The Norman W. Henley Publishing Co., 1920. 8vo.; 410 pp. 153 illustrations.

The thoroughness and lucidity of this writer's instruction books are readily acknowledged by the army of students and readers which profits by them. This enlarged and revised edition of his work on the Ford car deals also with truck and tractor conversion sets, the Fordson farm tractor, and the F. A. lighting and starting system. Its multitudinous diagrams and photographs of actual parts are all in correct proportion, and materially assist the student in grasping details of construction, operation and repair. It is practical experience reduced to black and white—just such concrete facts as owners and drivers, dealers and repairmen should know.

UTILISATION DES ALGUES MARINES. By Camille Sauvageau. Paris: Librarie Octave Doin, 1920. 12mo.; 394 pp.; 26 illustrations.

Seaweed furnishes many valuable products. Potash, iodine, and adhesives are obtained from it; it is in use as a fertilizer, as food for animals, and even as food for man. M. Sauvageau, at the invitation of the *Direction des Inventions*, has given us an instructive work on French and foreign marine algae and the methods by which they are made to serve useful purposes, including American processes. He enumerates medical uses and gives the species used as bait by fishermen, while the identification of varieties is aided by numerous drawings.

A LAWYER'S LIFE ON TWO CONTINENTS. By Wallis Nash. 12mo.; 211 pp.; illustrated. Richard G. Badger, The Gorham Press, Boston.

Each phase of the experience, here so entertainingly set forth, covers some forty years of an extremely active life. The author relinguished a lucrative practice to assume the vice-presidency of a pioneer western railroad, the Oregon Pacific. Wallis Nash, throughout his long and busy life, has been a keen and discriminating observer of men and things; he writes with a facile pen and every page of these reminiscences is full of interest. Particularly so are the pen sketches of notable men with whom he was in close professional and social touch during his life in London. Thus, it was his good fortune for many years to be a neighbor and intimate friend of Charles Darwin. Speaking of Darwin's almost uncanny memory, he records how he went to Darwin's study and consulted him about a certain bug that was working havoc among his grapevines. "Go upstairs," said Darwin to his son Frank "and on the third shelf from the top of the left-hand book case you will find the journal for 18— of such a German Etymological Society. About page 257, on the right of the book and midway down, I think you will find the description of the insect and its life's history." And there or thereabouts we found it. It fell to Wallis Nash to handle the Bell patents in Great Britain, and he describes Bell as being in the 70's, a "tall, black-haired, handsome and very attractive man of thirty." At a meeting of the Society of Arts, he writes "the young lecturer made a very excellent impression; his effective and pleasantly modulated voice reached every person present." He speaks of playing Beethoven to Herbert Spencer "who sat by the piano and talked of the connection between brain and hand and eye in the interpretation of music." Another friend was Sir John Lubbock, and another the great Bessemer, who would talk freely of his early struggles, when funds were so low that even his wife's wedding ring was sacrificed—this on the eve of his final success.

AUTOMOBILE STARTING, LIGHTING AND IGNITION. By Victor W. Pagé, M.E. New York: The Norman W. Henley Publishing Company, 1920. 8vo.; 815 pp.; 492 engravings.

This is an enlarged, revised edition of a deservedly popular work by an author whose name is a synonym for the very best in automobile instruction. The repairman has to handle a wide variety of ignition systems; each variety, with its failures and their remedies, is made plain to him here. Elementary electric starter principles, and typical starting and lighting systems, their faults and the speedy location of them, are dealt with in the thorough fashion for which the writer is famous; there is a chapter on the design of electrical measuring instruments and their use in testing; the whole is prefaced by a chapter on elementary electricity, and every detail is opened to the eye by means of clean-cut figures, plates and diagrams.

AN INTRODUCTION TO THE STUDY OF CYTOLOGY. By L. Doncaster, Sc.D., F.R.S. New York: G. P. Putnam's Sons, 1920. 8vo.; 280 pp.; 31 figures, 24 plates.

The writer believes that cytological investigation is one of the most promising leads toward biological advance; his work, of wider scope than the text book, not only gives the important facts of animal cytology, but indicates how research in this branch is bound up with great fundamental problems. Careful selection is necessary to so condensed a treatment, and on the whole this has been successfully accomplished. The book describes the cell and cell phenomena, discusses accepted theories, and touches upon the mechanism of hereditary transmission and the rôle of the cytoplasm.

LUCK ON THE WING. By Elmer Haslett, Major, Air Service, U.S.A. New York: E. P. Dutton and Company, 1920. 8vo.; 303 pp.; 8 plates.

The humorous and the dramatic alternate through these stories of a sky spy. As Gen. William Mitchell points out in his laudatory introduction, the book has a double value: it is a truthful, gripping picture of the life of our air fighters during the great actions of Chateau-Thierry, St. Mihiel, and the Argonne; and it plainly shows how the lack of understanding of the functions of the Air Service resulted in the dissatisfaction that prevailed. Hilarious incidents mark the writer's capture and incarceration, and the stories are as well worth reading for their humor as for their information.

EXPERIMENTAL ORGANIC CHEMISTRY. By Augustus P. West, Ph.D. Yonkers-on-Hudson, New York: World Book Company, 1920. 8vo.; 469 pp.; illustrated.

In this college textbook a well-known instructor embodies the method he has long successfully used in mimeographed form. One of its claims to attention is that it combines textbook and laboratory manual in one, with printed directions that permit the student to do his own work, thus at once saving the instructor's time and developing self-reliance in the pupil. Dangerous and difficult experiments are excluded, exactitude in the preparation of compounds is insisted upon, searching review questions follow each chapter, and there are numerous charts, diagrams, and structural formulæ.

THE MOST SCIENTIFICALLY BUILT WATCH IN THE WORLD

## The Waltham Scientific Method of Mounting Jewel Bearings that is so Important in Your Watch

THE bearings of a watch are jewels because a precious stone is the hardest known substance for use in this important function. The harder the material and the smoother its polish the less resultant friction.

The chief problem confronting the old-time watchmaker when he first conceived the idea of using precious stones was a correct method to secure properly the jewels in the plates of the watch.

To do this, he cut a seat in the watch plate, then with a sharp tool forced the metal over the edge of the jewel.

So important was the necessity of securing the jewels rigidly in relation to their bearings (with the pivot hole exactly in the center and the jewel in perfect alignment with the plate and pivot so that the jewels could be removed easily for cleaning or repairing when injured) the Waltham Watch Company, after years of painstaking development, created a scientific method of jewel setting which made it easy for the jewels to be so removed and reset without affecting in any way the original time-keeping quality of the watch.

This scientific Waltham Method secures the jewel in a separate brass or gold setting. This setting is cut to a diameter to fit perfectly its aperture in the plate, then pressed to its correct position in relation to the pivots (or axle) completing the jeweled bearing.

The special tools invented by Waltham so expand the jewel setting in its aperture that it becomes rigidly located. This eliminates the method of using holding-screws and greatly simplifies the work of the watch repairer whenever it is necessary to replace a jewel bearing.

The Waltham Scientific Method of mounting jewel bearings is a distinctive and better way of securing the jewels in the setting, and also of the setting in the plate. It provides the easiest and safest way for the repairer to handle your watch. It protects the original time-keeping quality of the watch. It reduces up-keep and insures a continuous satisfaction because of dependable time-keeping service.

This is one more reason, in addition to many others of like value, why your watch selection should be a Waltham.

*Covered with Johns-Manville Asbestos Built-Up Roofing.*

*Residence of Mr. G. Schrader, Pasadena, California, Roofed with Johns-Manville Asbestos Shingles.*

# Both these buildings have one virtue in common—an Asbestos Roof

FOR this great public museum the architect sought the best roofing.

For the modest dwelling the owner sought the most *economical.* Both chose Johns-Manville Asbestos Roofing.

But you may say, "How can *the best*—inferring quality and high cost—be also economical?"

The answer to this lies at the very base of the reason for Asbestos in roofing form.

The vision that 25 years ago saw in Asbestos the future roofing material, had but two factors in mind—long life (without upkeep cost)—and safety from fire.

These are the properties of Asbestos, translated into an ideal roofing specification.

In considering Asbestos as your roofing, remember the keenest calculators of building costs and building-up-keep have adopted it as standard and not because of the novel fact that it is the only all-mineral roofing felt or slab, but because of its positive immunity from rot, drying out or decomposition, which mean constant roof attention and repair. It is as inert to the weathering elements as it is from fire—not only lasting but fire safe; a new standard for a roofing to meet.

In the list below you will find a Johns-Manville Asbestos Roofing for the particular type of building you have in mind.

JOHNS-MANVILLE ROOFINGS

*Left:* An exceptionally accurate perforating punch-and-die used in turning out high-grade electrical apparatus. *Center:* A rather unusual assembly of an ordinary micrometer and a liquid gage that multiplies its measurements by more than a thousand. *Right:* The punch-and-die machine taken apart to show its internal construction.

**Some of the tools that are used to translate the hundred-thousandth of an inch into practice**

## Splitting Hairs With Close-Limit Tools

By Alfred Longville

WHEN is an inch not an inch? The question is not a brand new conundrum; it is asked in all seriousness. One would answer correctly by saying that 999 one-thousandths of an inch is not an inch. To the layman such a trifle as a ten-thousandth of an inch might not be of much moment. But in the making of tools which turn out certain electrical apparatus an inch isn't exactly an inch if it's even a hundredth of a hair too long or short.

What does the average person visualize by the term a ten-thousandth part of an inch? Said person might smile and say there is no such thing. It would not be missed off the end of a yardstick, might be the contention. Yet as certain as little drops of water go towards the making of an ocean, so would an inch disappear entirely if one continued to chop ten-thousandth parts of it away. The same would be true if one were to divide the ten-thousandth part by ten and make it a one hundred-thousandth part of an inch. To most minds an inch is small enough and any smaller dimension is hardly to be reckoned with. Yet as small as it is, if it were possible to slice an inch into one hundred thousand parts and slice off each part as rapidly as one can deal playing cards from off a deck, which is about four to a second, six hours, fifty-six minutes, and forty seconds would elapse before the last one hundred-thousandth of an inch was sliced off.

In order that one may get a better idea of a hundred-thousandth part of an inch, or even a ten-thousandth part of an inch, let one place one's imagination to the eye-piece of a compound microscope, under which there is a filament of some substance a ten-thousandth of an inch in diameter, side by side with a human hair of average size. Seen through the ordinary microscope, the hair would look about the size of a lead pencil. Yet the ten-thousandth of an inch filament, magnified to the same extent, would appear about as thick as the human hair.

If one by this time is able to imagine a tenth of what is left of that ten-thousandth part, after it is taken away from the microscope and does not appear magnified, one may begin to understand something about close-limit tools, one of which is a punch and die for perforating used to turn out certain electrical apparatus. This particular tool is composed of a certain number of similar sections, so nearly alike that their thickness does not differ as much as one thousandth part of an inch. And if one by this time has been able to imagine just what this minute measurement constitutes, one is no doubt awaiting with an amazed expression to learn just how any one can possibly determine whether an inch is exactly an inch or only 999 one-thousandth parts of an inch.

The ways of telling are diverse and interesting. When a tool-maker is at work on a given block he generally uses what he calls an "indicator gage." This gage consists of a flat disk on which the measured piece is placed, and a small cylindrical upper jaw, movable in a vertical direction. This upper jaw connects through a series of levers to a pointer, which moves over a scale. Owing to the leverage, this pointer moves about one-sixteenth of an inch for every ten-thousandth of an inch movement of the upper jaw. Therefore, with the upper jaw so set that the pointer will rest on the zero line when the standard adjusting block is in the gage, a practical tool-maker can compare another block with the standard without getting much over a hundred-thousandth of an inch error. To make sure of that hundred-thousandth the blocks are checked in a measuring machine in which the indicating jaw is connected to a liquid gage that multiplies 1,300 to one. This gage is simply a relatively large cylindrical chamber with a small-bore glass tube projecting from the top. The front of this chamber is closed by a flexible diaphragm, against which the far end of the indicating jaw rests. When this jaw is opened a small amount it pushes the diaphragm a little way into the chamber. Now, if the chamber is entirely filled with a liquid, this movement of the diaphragm will displace some of the liquid and force it up the small glass tube. Since a very small quantity of liquid goes a long way in a very small diameter tube, it is easy to see how such a gage can multiply the movement of the indicator jaw 1,300 times.

**A grinding machine that produces work accurately within the twenty-thousandth of an inch**

*Comparing* two lengths within a hundred-thousandth of an inch is no trick at all on this machine. But so little cannot be said of *getting* them to within a hundred-thousandth of an inch. The later stage comprises a series of tricks, to master all of which the most skilled tool workers would be hard put in a single life time. Because of this fact the tool-makers are specializing in their work.

Various operations, such as milling, lathe work, grinding, fitting, etc., are done by different groups in which men exceptionally good at one branch of their specialized sub-work keep at that sort of work exclusively. Because of this kind of specialization it is possible to build a tool as large as the perforating punch and die and at the same time get it within the degree of accuracy required. It would be possible to do so without this specialization, but the cost and the length of time involved in the completion of such a tool would be prohibitive by the methods used in most tool-making establishments. Outside tool-makers who have not specialized in this work declare that it is practically a commercial impossibility to make such a tool.

The commutator-strip perforating punch-and-die is built up of 50 punch sections, 50 die sections, and 50 shedder sections. Each punch section is exactly like every other punch section, each die section exactly like every other die section, and each shedder section exactly like every other shedder section, granting that one-hundred-thousandth of an inch is close enough to signify exactness.

The method by which the tool-maker makes them that way is peculiarly interesting. At first the parts are machined and ground to what the most exact person would term a high degree of accuracy. After this they are hardened, during which process a certain amount of distortion always occurs, following which they are submitted to the real job of being ground. They are ground to within five one-hundred-thousandths of the standard size, which constitutes a real job in grinding. It requires the very best of machines and the very best of operators, familiar with all of the idiosyncracies of their machines, to produce work of such accuracy. This job is better appreciated when

## Shifting Lines

THE definite profession of the engineer is of comparatively recent origin. There have, of course, always been men under whose eyes the work of the world has been done. The Roman highways, the bridge of boats that gave the Persian access to Europe, the pyramids, the great works of the Mesopotamian plain—all these called for what we recognize as engineering instincts and abilities in the conception, the planning and the execution. Even the early arts, like bow-making and pottery and boat construction, are examples of primitive engineering skill—the making of anything that comes out as it was intended to come out and that serves the purpose for which it was planned is engineering work. But throughout the prehistoric, ancient and medieval periods and well into the modern, the engineer was merely the boss artisan.

With the widening of human knowledge since, say, 1800, the effort to keep this corpus in order and to apply it to concrete cases as they arise has demanded a special profession. To meet this demand the engineer was created—or created himself; and he has been in existence long enough for us to get something of the historical viewpoint toward him. Various aspects of this viewpoint might be emphasized; the one that inspires these remarks has to do with the manner in which the vast field of the engineer was, and the manner in which it now is, subdivided. There has been here a significant shifting of lines.

Originally we had the civil and the mechanical and the electrical engineer. From the day when the engineer was first called on for evidences of specialization within his field, he followed one of these three directions. The first-named would apply his knowledge with equal facility to the laying out of a railroad or the surveying of a new country or the erection of a great bridge or the designing of a floor to carry a heavy load or the throwing of a dam across a stream or the location of the best highway between two given points. The second found it a matter of indifference what sort of a factory he was sent to, or what manner of machinery he was asked to install or maintain there. And the last-named was quite prepared to work in telegraphy today, in dynamos tomorrow, in street-car motors or trolley wires the next day, and in electrolysis next week. The engineering field was divided according to the raw materials of the engineer, and, so divided, it fell naturally into the three domains outlined—that of the engineer whose raw material is electricity, that of the one who does things with machines, and that of him who works with the static forces of the visible external world.

In the beginning of the profession this was altogether satisfactory. It has not remained so. The first sign of a break in the old scheme came early, with the segregation of the mining engineer as a distinct sort of animal. To qualify for this profession a man had to have some of the equipment of each of the three preexisting groups, but in none of these fields did he require complete training. The reason for building up this composite of the three existing branches and giving it a name and a standing of its own was the very excellent one that mining work called for all three types of service, yet made demands which it seemed should be possible for one man to meet. So the man arose to meet them, embodying in his own equipment the elements of the necessary coöperation between civil, electrical and mechanical engineering, making his own such parts of these three fields as he needed in his business and discarding the rest.

Eventually the process was repeated, not in one but in many instances. What it then came to was the regrouping of the engineers on a new basis. It would mean nothing today to claim to be a civil or a mechanical or an electrical engineer—it would give not the least information as to what the claimant was qualified for and what he was not. For today we have railroad-signal engineers and automotive engineers and safety engineers and marine engineers and turbine engineers and dock engineers and conveyor-belt engineers and magneto engineers and highway engineers and subway engineers—and a host of others which we have neither the time nor the space nor the patience to catalog. Each of these professions is distinguished from the others, not so much in what the incumbent has by way of technical equipment as in what he does with it. So the old division on a basis of raw materials has passed away, and today we catalog our engineers according to their finished products.

This is eminently sensible and eminently modern in viewpoint. Three thousand years ago it was natural and proper to group workers according to the material in which they worked. In those simple days a man was a mason or a carpenter or a weaver or an ironsmith or a coppersmith or silver-and-gold smith. At that date it would have been ridiculous to group the mason and the tent-maker together on the mere ground that both were engaged in the construction of human habitations. But with the multiplication of tools and of knowledge, it would be just as absurd to catalog a manufacturer of telephone wire and a photo-engraver in the same group on the mere ground that they both use copper as a raw material. We prefer to regard the wire maker as an industrial brother of the battery builder and the man who makes composition stands and mouthpieces, while we relate the photo-engraver with the compositor and the pressman—substituting a classification that follows the finished product for the one that follows the raw materials employed. So it is in the engineering field, and properly. Civilization weaves so complex a web of causes that we find it far easier to distinguish and identify results.

## When the Grim Specter Stalks

PLAGUES, we ordinarily think, are a thing of the past. Now and then we have isolated cases, even local epidemics on a small scale, of smallpox and the bubonic plage. But with the word "plague" we associate a phenomenon that is distinctly obsolete—the utter ravaging of whole countries and continents by a pandemic that is swift in its spread and high in its percentage of mortality.

The reason for this is of course that we know more than our ancestors did. Yet with all our knowledge, we are not free from plagues that, considering our improved ability to meet them, make away with a disgracefully large proportion of our numbers. The great plagues of history have been to all intents and purposes stamped out, and our success in achieving this end is attributable to the fact that every one of these plagues, with one exception, was transmitted through an intermediary agent. We can exterminate the rats and the mosquitoes, we can regulate the milk and water supply, by a simple exercise of the police power. Even in the case of smallpox, there is the almost certain prevention through the single, simple act of vaccination; and this, too, can be enforced through exercise of the police power.

But the plagues of today—the minor ones, such as scarlet fever, whooping cough and measles, or the major ones, such as influenza, pneumonia and tuberculosis—are transmitted in quite a different fashion, and require for their ultimate stamping out measures of quite a different character. They are independent of intermediate hosts and to a great extent of food and drink pollution. Their eradication depends not alone upon compulsory isolation of reported cases, but upon personal habits as well. Transmission is strictly through personal contact. Many of these maladies are transmitted during their early stages, before a diagnosis is possible and hence before specific protection against the individual carrier can be effected.

So where originally the health officer required merely the qualifications of a policeman, he must now add to these the training of an engineer and the abilities of an educator. The combination is doubtless a rare one; but to prevent the spread of disease all three of these functions must operate. The finger which goes to the nose and then to the doorknob must be restrained; the unguarded sneeze or cough in the public place must be made to yield to education. The offender must learn that he is restrained, not necessarily because of any belief that he is actually spreading disease—to the person of average good habits there is something particularly insulting about this suggestion, even when he realizes that he necessarily carries with him at all times a choice collection of the germs of all the standard diseases, which only await the opportunity to become active—but merely in the execution of a general policy. Even if we believe that a particular member of the community has no germs to spread, we cannot permit him to do things that are forbidden to those who may have such germs—we might as well allow respectable citizens to jimmy their way into locked houses just for the fun of so doing, and punish only those wielders of the burglarious tool whose intent can be proved felonious. The public at large must be educated to an understanding of the fact that its protection requires certain rules to be laid down for observance by everyone, without exception. When this viewpoint is general, and when the people at large have so thorough an understanding of health protection that adequate moral and financial support will be extended to the health administration, we may find that tuberculosis and influenza and pneumonia and scarlet fever are no more necessary concomitants of community life than were bubonic and typhoid.

## Greek Kakophony in the English Language

IT has been remarked that practically everything worth while in our modern civilization can be traced back to the influence of Greek antiquity. Far be it from us to say anything derogatory of our debt to the sages and poets of Hellas. But it is human to feel our little itching discomforts more than the solid blessings of life. So we cannot help wishing, sometimes, that our Greek heritage had come down to us without collecting an irksome tax; without inoculating upon our good old English tongue the germs of such philogical antics, as for example, *poikilotherm, enantiomorph, schizophrenia, epistemology,*—and, horror of horrors, such words as *syzygy* and *phthisis.*

Presumably we may charge this influx of uncouth aliens into our technical terminology, in the first instance, against the early classical scholars, who set the fashion since followed. Whether we owe them a debt of gratitude for this may be left undiscussed. But when we reflect upon the offense to tongue and ear which these verbal monstrosities commit, we are set wondering whether the lover of the dead languages has quite as fine an ear for euphony as he, no doubt, would have us believe. Perhaps enthusiasm has clouded better judgment. We recall, in that dim past when we were gracing the school bench with our (then) juvenile presence, how our revered classical master, one afternoon, held forth to us about the beauties of the Greek language. His remarks were pointed with a reading from Homer, which he rendered with fine fervor; totally oblivious of the fact that, had he been addressing a Greek audience he might, indeed, have made a lively impression upon their sense of humor, but certainly could have made little appeal to any other faculty. For scarcely a word would they have understood of the gibberish into which their words were distorted by his English pronunciation.

There they are now, firmly rooted in our native tongue, those words of foreign sound; refusing to fall into the natural cadence of our speech; shuffling along in the procession of our discourse as the limping, the lame and the halt in a gay parade. Uncouth, incongruous, they stand out against the sober background of language like the offending patch in the seat of a boy's breeches.

## Electricity

**Electric Hatching of Chicks.**—A third of a million chickens a season is the proposed capacity which a customer of the Electric Power Company of Portland, Ore., intends to attain in his electrically-operated chicken farm known as "Henacres." His output this season will be in the neighborhood of 100,000 chickens, as compared with 45,000 for last year. This farm started with one small electric incubator in 1915 and now is equipped to operate on a large scale, having a single incubator with a capacity of 20,000 eggs. The total connected load for this plant consists of 33.5 kilowatts of heating and 3 kilowatts of lighting. For emergency service, continues *Electrical Review*, a 20-kilowatt direct current generator is installed at the farm and is so arranged that it may be driven from the owner's truck.

**Britain's Wireless Chain.**—The long-contemplated plan to connect all parts of the British Empire by wireless telegraph has received fresh impetus through the issue of a report of the committee appointed by the Government to formulate such a scheme. The committee's report, which is unanimous, recommends that the Empire shall be linked up wirelessly by stages of about 2,000 miles each and that the system employed shall be that of the generation of radio-telegraphic energy by vacuum tubes. The scheme contemplates two main chains of wireless, one receiving dispatches from Africa and the other from Asia and Australasia, both with Cairo as their first station. For the first link of the first chain a connection would be made on the Poulsen arc system between Oxford and Cairo, which the Post Office Department has nearly completed.

**Electric Purification of Air.**—In a recent *Comptes Rendus* there appears an interesting account of experiments conducted by D'Arsonval, Bordas and Touplain of France, on the electric purification of air. A simple apparatus was used for this purpose, namely, a brass tube 1 meter long with an axial wire, air being passed through the tube at the rate of 127 cu. m. (4,500 cu. ft.) an hour. The air was purposely polluted with a fine sterile mineral powder and also with dried cultures of a certain microbe. After passing through the tube, the central wire being maintained at a negative potential of 50,000 volts, the air was found to be absolutely sterile, while 95 to 97 per cent of the powder was removed. Before passing the tube samples of air gave 150 cultures of the microbe per cubic meter. It is suggested that the ozonization may have aided in destroying the microbes.

**A Vacuum Tube Transmitter.**—In order to utilize a radio-frequency wave train of given power most effectively in a non-oscillating receiving system it must be completely modulated at some suitable audio frequency. A convenient way of accomplishing this modulation, when an electron tube generator is used, is by supplying the plate circuit of the tube or tubes with an audio-frequency alternating current. An alternator may be used with suitable transformers to supply both the filament and plate circuits. A self-contained transmitting set of this type has been designed and built at the Bureau of Standards, Washington, D. C. A description of the set, with photograph and diagrams, is given in the Bureau's Scientific Paper No. 381, entitled "An Electron Tube Transmitter of Completely Modulated Waves." Overall efficiency as high as 35 per cent is obtained with the set.

**Durability of Electric Heaters for Distillation** of gasoline is covered in one of the recent reports of the Bureau of Mines. An electric gasoline distillation heater and a commercial device sold for the same use have been subjected to life tests at a maximum current load. Each failed at the end of approximately 500 hours, the bureau heater through deterioration of the resistance wire and the commercial heater through disintegration of the block of insulating material holding the resistance wire. The bureau heater has an inverted conical resistance element surrounded by a layer of heat-insulating material and mounted in a metal case having a top of hard asbestos board. The resistance element is a helix of nickel-chromium alloy wire held by a molded core of alundum. The commercial heater has a helix of nickel-chromium alloy wire resting in a spiral groove cut in a depression in a block of heat-insulating composition. The coils of wire are held in place by a special cross of sheet mica.

## Science

**The Centenary of Sir Joseph Banks,** who died June 17, 1820, was commemorated June 17 of this year by the Linnean Society, in London, with a program of papers relating to Banks and his work and an exhibition of objects connected with his life. One of the papers presented was, the author stated, based on the daily use of specimens from Bank's herbarium, now in the British Museum. Sir Joseph Banks, Bart., was president of the Royal Society for 42 years.

**A New Journal of Genetics,** known as *Hereditas,* has just been started by the Mendelian Society of Lund, Sweden, the president of which is Prof. H. Nilsson-Ehle, well known for his breeding experiments with wheat. The journal will be published about three times annually, and will contain papers in English, French and German. It will deal with problems of man as well as of plants and animals. The subscription price is 25 Swedish crowns per volume.

**Protection of Alaskan Animals.**—In accordance with a recent Act of Congress, the duty of protecting land fur-bearing animals in Alaska, formerly entrusted to the Department of Commerce, was transferred July 1 to the Department of Agriculture and has been assigned to the Biological Survey of the latter department. The Secretary of Agriculture has issued regulations conforming generally to those previously in force with regard to the hunting of the animals in question, shipment of furs, etc.

**A Student of Ball Lightning.** The Reverend Ignazio Galli, ex-director of the observatory of Velletri, who died February 1 of this year, at the age of 79, was one of the most interesting personalities in the scientific world of Italy. We had occasion, a few years ago, to refer editorially to Galli's keen interest in the project of reviving Latin as the international language of science. He has been a versatile writer on scientific topics, but has been especially prominent in recent years as a collector of information concerning the still enigmatical phenomenon of ball lightning on which he has published a long series of papers.

**International Geodetic and Geophysical Union.**—National unions affiliated with this international body have been organized in Great Britain, Japan, France, Canada and the United States. Each national union has its subdivisions, representing individual sciences. The American Geophysical Union, permanently organized this year under the auspices of the National Research Council, elected officers April 23. Mr. Wm. Bowie of the Coast and Geodetic Survey is chairman, Dr. L. A. Bauer of the Carnegie Department of Terrestrial Magnetism, vice-chairman, and Dr. Harry O. Wood, secretary. A new section devoted to geophysical chemistry has been added to this body.

**The Meyer Memorial Medal.**—When the well-known agricultural explorer, Frank N. Meyer, lost his life in the Yangtze River, in 1918, he left a bequest of a thousand dollars to the staff of the U. S. Office of Foreign Seed and Plant Introduction. The recipients of this bequest have put the money into a permanent tribute to Meyer's memory in the shape of a medal to be awarded for distinguished service in plant introduction. The awards are to be made by the council of the American Genetic Association. The medal was awarded for the first time on May 3, 1920, the medalist being Mr. Barbour Lathrop, one of the founders of the plant and seed introduction work of the United States Government.

**Long-range Weather Prophets.**—The erudite and versatile director of the Prussian Meteorological institute, Dr. Gustav Hellman, has recently issued a second series of contributions to the history of meteorology, one paper of which deals at length with the non-scientific long-range weather forecasters of the 19th and present centuries. The popular celebrity acquired by many of these persons is a remarkable example of human gullibility. Although we miss the names of some recent American weather seers of wide reputation, Dr. Hellman's list is impressively long. He gives detailed accounts of the activities and publications of 105 long-range forecasters, distributed as to nationality as follows: Belgium, 2; Germany, 36; England, 25; France, 14; Italy, 2; Austria-Hungary, 8; Russia, 1; Sweden, 1; Switzerland, 5; Spain, 2; North America, 9.

## Aeronautics

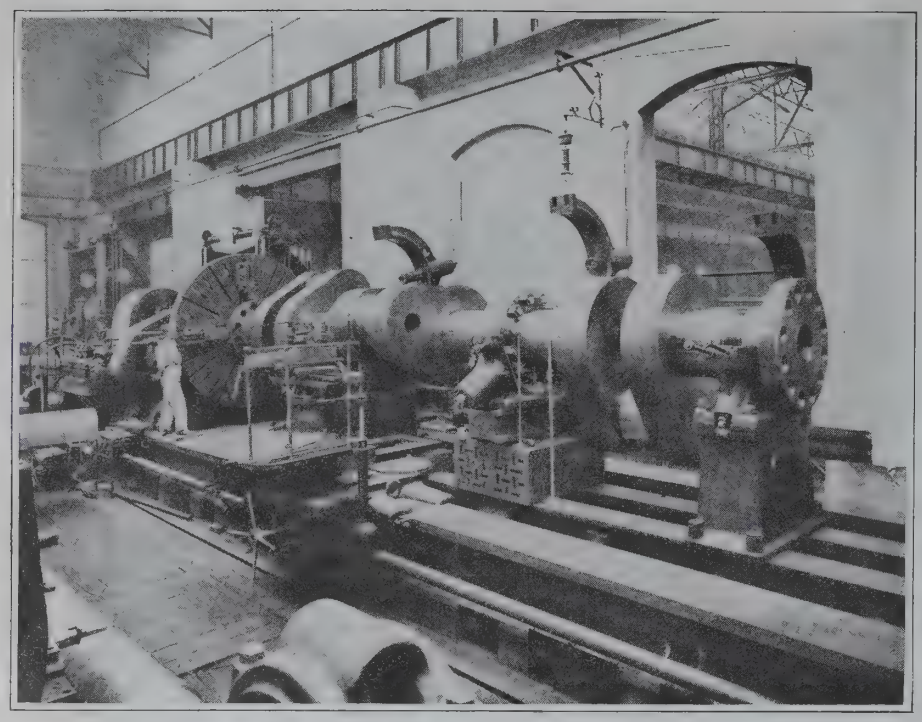
**Army Airplanes Have Reached Alaska** after a flight from Mitchel Field, Long Island. Four machines started on this long journey and every one finished. They came to ground on the flats of the Stikine River, some seven miles from Ketchikan, Alaska.

**Clear View in Bad Weather** is the object of a special screen devised by an Englishman, George Kent, and now being used extensively on the most up-to-date British planes. The clear vision screen is simply a disk of glass driven at a high rate of speed either by a small propeller carried on one of the struts, or by vanes fixed around the periphery of the disk. The disk, half of which is exposed, comprises the entire windshield. It maintains clear look-out in spite of rain or snow, or even oil thrown from the engine or tractor.

**An Auxiliary Starting Battery.**—In order to conserve the storage batteries which are a part of the equipment of the Curtiss Seagull three-seater flying boat, the Curtiss Flying Station at Atlantic City, N. J., has devised an ingenious device which has materially cut down costs and energy. The station fleet of flying boats is kept busy in passenger carrying. Between each flight ranging from 15 to 25 minutes, the motor is stopped necessitating considerable wear of the battery which is used on the self-starter. To eliminate the cost and bother of recharging the batteries, this flying station has introduced a small handcar or "baby carriage" which carries the largest sized regular storage battery made. To start the motor of a flying boat, the "baby carriage" is wheeled up alongside and proper connections made. Thus the small storage battery aboard the seaplane is reserved for emergency purposes.

**The "Joy-Stick" Patent Claims.**—The war served to make us forget, at least temporarily, the matter of aeronautical patents. But with the excitement and rush of wartime aeronautical construction at last subsided, the various patent suits which have been hanging fire all these years are again coming into action. Thus French and British aircraft constructors are no doubt losing considerable sleep over the claims of M. Robert Esnault-Pelterie, who in 1907 patented the single lever for operating both longitudinal and lateral controls. Some time before the outbreak of the war in 1914 he instituted proceedings against various firms of airplane constructors, which, however, were interrupted by the outbreak of hostilities. In 1918 this inventor and aviation pioneer reopened his action against alleged infringers of the patent in question, claiming a sum of 2,000 francs in respect to each machine fitted with the device. It is estimated that the total sum involved is something over 50 millions of francs.

**Should We Import Foreign Planes?**—There is considerable feeling amongst American aircraft manufacturers concerning the importation of British and French machines into this country. The disposal boards of these countries have resold at a low cost to various firms the machines due under contract. Hundreds of these aircraft were never used owing to the armistice. Now these machines are being sent over here and are put on the market at a figure with which the American manufacturer is at present unable to compete. On the face of it, competition of this class is scarcely fair. It is true, of course, that the majority of the Americans who flew in France used British and French machines for the good reason that there were almost none of American make there before the armistice. There is no doubt that the boys got to know and to like the foreign makes, and there will be a natural tendency for them to buy the types whose record they know and which they know how to handle, particularly at a lower price than the entirely American machine can be turned out. The American aircraft industry has still a lot to learn from foreign technique, however, and the introduction of these aircraft should stimulate them to increased production. To prevent foreign entries by legislation is merely to hamper the advance of aviation and to put this country far behind Europe in the development of the science. If there were no demand for foreign machines there would be no supply.



Machining a huge crankshaft for marine use in the factory that used to make Austria's guns

## How the Austrian Krupp's, Under Czecho-Slovak Auspices, Is Producing Munitions of Peace

By Arthur J. Herschmann and Carl Scheid

AMERICANS are apt to form a wrong idea of what the new republic of Czecho-Slovakia comprises and what it is. The population is about 12 million and the territory about 130,000 square kilometers. Composed for the most part of the old kingdom of Bohemia with its wealth in gold, silver, iron, lignite, coal, graphite and radium, its chief adjunct is Moravia, which country is a very large agricultural and industrial factor. The railroads of the new republic measure about 6,000 miles and there are some 200,000 men employed in the iron industry of the country. During 1917 the production of the iron industry was 17 million hundredweight and there were imported from Sweden 10 million hundredweight of iron ore, quartz, coke and coal from Germany, besides limestone from Poland, and ferromanganese from Jugo-Slavia.

Great and significant changes are going on in the industries of Continental Europe and while we Americans are looking on, the other big nations are taking an active part and are becoming connected with the leading enterprises of the new republics. English and Italian interests have bought into Austrian steelworks and engineering plants, and chief among the French investments we will here concern ourselves with the famous Skoda Works which are now controlled by Schneider of Crusot.

Emil von Skoda took these works over in 1869 when they employed but 150 men on engineering work of a general nature. Today these works have a capital of $29,000,000 and an area of 1,325 acres of which 100 acres are built upon. There are over 7,000 machines and the horse-power generated within the works is 43,500. There have been as many as 3,000 clerks and office employes and over 33,000 men at work in the shops. The Skoda Works own their coal and iron mines and are equipped in the most thoroughly modern way. Together with their subsidiary plants they are self-sufficient and can produce almost anything that is made out of metal.

The headquarters are at Prague; the technical offices as well as the administrative departments are at Pilsen, Bohemia, where the works are located, west of Prague. Here are 9 Siemens-Martin furnaces equipped with most modern charging devices and operated in part as basic and in part as acid furnaces; they have a combined capacity of 300 tons and steel castings up to 100 tons in weight can be turned out of any quality and finished or in the rough. This department has supplied rudderposts, propellers, foundation plates, crankshafts and the like for the best known passenger vessels and warships of many European and Asiatic nations. Skoda Works make the softest dynamo steel of highest magnetic quality as well as the hardest steel for stone crushers, cement mills, and the steel department also produces flywheels over 60 tons in weight, wheels for water turbines, frames for rolling mills, anvils, railroad material of cast steel, etc. There is a special ingot foundry to serve the forges and rolling mills. Here large blocks are put under high pressure after the "Harmet" process and alloys are produced, free from blowholes, up to 105 tons in weight.

The foundry has 22 electric traveling cranes and 7 hydraulic jib cranes from 10 to 80 tons capacity, 7 large drying ovens besides large numbers of molding machines and a plant for the preparing of the sand.

Then spacious tempering ovens serve to treat the castings after they have been cleaned with compressed air tools, sandblast and cleaning machines of various kind. There are 2 magnetic traveling cranes with a span of 135 feet and a lifting capacity of 6 tons. The foundry has its own machine shop of over 12,000 square yards floor space, 11 electric cranes and among the tools is one which will turn pieces measuring 35 feet in diameter with great accuracy.

Here are steel furnaces of 4- and 6-ton capacity for thin quality castings of electric steel and 5 converter steel furnaces of 2 tons each. The iron foundry has several cupolas with Dutch ovens of an hourly capacity of 45,000 pounds, and there is a gas-fired furnace for the melting of quality iron which has a capacity of 10 tons. This department also contains 8 electric travelers from 3 to 60 tons capacity.

The metal foundry has 17 furnaces and produces castings up to 11,000 pounds in weight. Every kind of bronze is made, forged or cast, and the manufacture of aluminum castings of special alloy for automotive purposes and internal combustion engines is made a feature of production. The pattern-making shop covers 7,000 square yards and contains up-to-date American wood-working machinery.

The blacksmithing branch of manufacture is maintained in 7 halls of 22,000 square yards and has 9 steam-hydraulic presses, the largest of 5,000 tons pressure, several large steam hammers, hydraulic crowning presses, several rolling mills for tire material for car wheels, locomotive and tender tires. This section commands over 60 electrically-driven machines of modern construction, including lathes of 12 feet swing and 90 feet between the points, vertical boring mills of 18 feet diameter of the work, and shapers of 6 feet stroke. Tools to finish crankshafts are here of an accuracy of 2/100 of one millimeter. Boring mills of this department can handle tubes of almost 100 feet of length.

Thirty heating furnaces serve to treat the ingots with thermo-electric devices. For transportation and for the forges 35 electric traveling cranes are installed of a capacity of from 10 to 60 tons. Forgings are made up to 180,000 pounds for marine purposes, shafts up to 90 feet in length (see illustration), piston rods, connecting rods, rotors for turbines, and rolling stock of every conceivable kind. In the small forge are 17 steam hammers from 50 to 1,500 tons in capacity and 63 fires, 15 cranes from 3 to 5 tons capacity besides 2 main gantry cranes. Pieces are forged up to 5,500 pounds in weight.

A building of 10,000 square yards houses the spindle press plant and contains

A novel kind of marine propeller made at the Skoda establishment

24 eccentric presses, 42 spindle presses with spindles up to one foot in diameter, 4 air hammers up to 300 pounds in weight, 4 shears up to 2 inches capacity. There is also the gear works with special machinery to produce wheels up to 15 feet in diameter of every material.

The locomotive works, which was founded in 1918, has 4 large buildings devoted to manufacture and repair of locomotives and to boilermaking. Over 200 modern tools produce the mechanical parts in the repair plant, and this young department already employs over 1,100 men and turns out and reconstructs 300 locomotives each year. The area covered is 33,000 square yards.

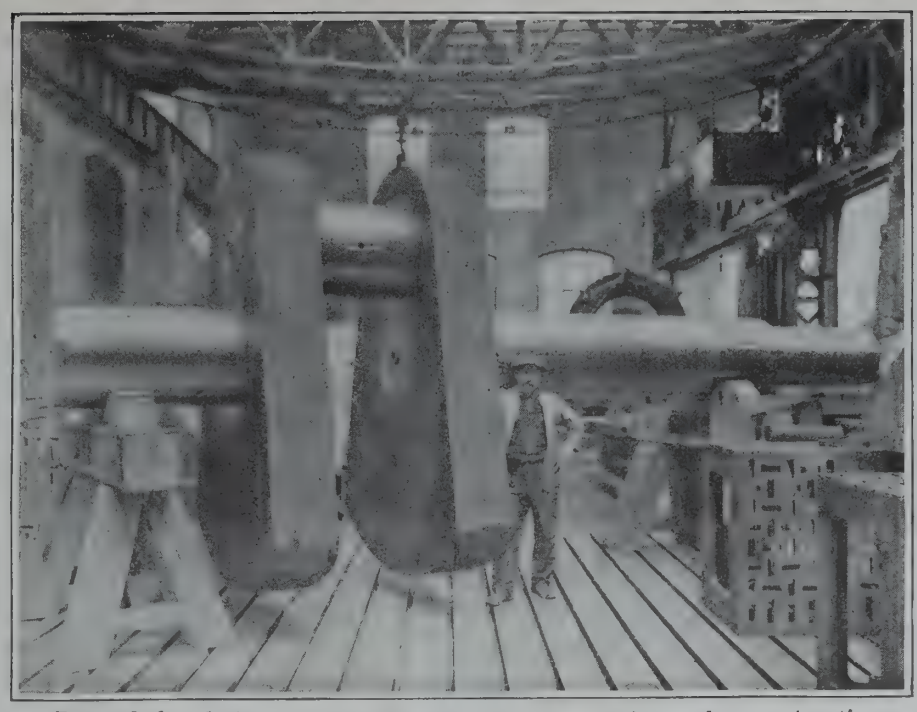
The automobile factory, which is a new department, makes tractors, ploughs and explosion engines. The area covered is 45,000 square yards and there will be employed 1,400 men. Up-to-date machinery is being added which will give a capacity of 900 motor ploughs and tractors, besides 1,000 agricultural locomobiles.

This great munitions plant, which has been famous for many years, is now being diverted to the making of printing presses, agricultural machines and the like. A separate testing laboratory is installed to insure perfect product and the Skoda Works have their own proving grounds where armor plates as well as projectiles and guns are tested. There is a complete munition works in connection with the gun works and there is a special testing plant for these munition works at Nuerschan and Bolawetz near by.

This large electric generating station furnishes steam and current for the entire works, does the driving and heating of the shops and produces oxygen and hydrogen for the welding and cutting flames. Electric current is supplied by the station 1 at the northern boundary of the works at Pilsen and the station 2 at the Pankraz mine in Nuerschan. Interconnection is made by long distance line of 8 miles in length which carries current of 50,000 volts and of 50 cycles.

An extensive mechanical carrying plant is installed for the handling of coal and ashes from and to the coal mines of the works. The main stacks are 250 feet in height and about 12 feet in diameter at the top. Exhaust steam is used for the heating during the winter season and the condensate from the turbines is fed back into the boilers. A filtration plant of 500 cubic feet hourly capacity supplies the make-up water of the boilers.

The turbogenerators range in size from 300 to 10,000 and are of 3,000 volts. There are 313 electric cranes ranging from 120 tons capacity down. Eleven of these are of 60 tons capacity. The installed horse-power of these 937 crane motors is 24,000 horse-power and there are besides 1,050 motors in the works of 25,100 combined horse-power. The oxygen plant is contained in separate buildings, also the hydrogen works. Electrolytic as well as "Linde" systems are here in use.



**Part of the shaft of a 10,000 horse-power gas engine under construction at the Skoda plant**

## The Greatest of Floating Cranes

By Ralph Howard

IT isn't every crane that looks the part. But there are very modern fellows that resemble their namesake pretty well. That is, they are capable of bending over to pick up something. The giant crane built for the British Admiralty is a case in point. The monster is very tall when in erect position. It may readily be bent over to reach a fairly distant load. Other notable instances of gigantic cranes of the same type are the two which are in service at the Panama Canal.

All three of these are mounted upon pontoons and are in consequence styled floating cranes. All of them are capable of lifting a maximum load of 250 tons. But the one which operates in British waters nevertheless outranks the others because it is able to secure and handle its maximum load at a greater horizontal distance. On may readily understand that, while the load lifted is a principal factor in a crane's capacity, nevertheless the outboard reach is also of importance.

Perhaps we ought to mention here another installation—a pair of cranes mounted on a single pontoon—each capable of lifting 200 tons so that the total of lifting ability exercised from the one pontoon is 400 tons. But this is hardly to be undertsood as an ability to lift and transfer, after the manner of a rotating crane, a single load of this total weight. The makers of the British crane claim the palm, and it may very properly be allowed them.

The greatest of floating cranes in the world is known in the British Navy officially by the very commonplace title of *Crane Lighter No. 4*. It lifts 250 tons at a radius of 100 feet. This is its greatest normal maximum effort. But it is capable of other normal maximum efforts. This requires a little explanation.

The arm which reaches out like the neck of a living crane and while at a more or less oblique angle provides support for the hoisting of the load is termed the jib. When the greatest of all efforts is made, the jib has an angle of perhaps 40 or 45 degrees to the horizontal. The lift is not made from the extreme tip of the jib but from a point somewhat back of it. The reach is estimated horizontally from a vertical plane through the center line of the pontoon to the steel ropes which support the load. The gravity pull of 250 tons at a distance of 100 feet from the center of the deck naturally tips the pontoon considerably. The height of the lift possible may be roughly estimated as the difference in level between the hook carrying the load when at its maximum height, and the lowest points of the tipped deck. Measured thus, *Crane Lighter No. 4* can lift the 250 tons at a distance of 100 feet to a level about 77½ feet above the water. Naturally, the block-and-tackle arrangement at the tip of the jib will, under the foregoing conditions, be at a higher level than the inner one. By depressing the angle of the jib, the reach possible with both blocks is increased. When the reach of the inner hoisting rig is at 110, 115, 130 and 137 feet, the possible maximum loads are 200, 150, 100 and 75 tons. At the farthest reach the jib is well-nigh horizontal. The block at the tip of the jib is capable of lifting 30 tons. This load may be lifted by the crane from this block at all reaches of the full jib up to 150 feet. It will be seen from the foregoing statements that this great crane is able to handle a great variety of work.

The pontoon which carries the crane is a pretty big boat, being 242 feet long overall and having a molded breadth of 86½ feet. The center of the base of the crane is somewhat forward of exact amidships. Suitable areas are provided on the pontoon's deck, ahead and astern of the crane for the loads to be handled. Consequently, with the crane exactly alongside of a position on a battleship where a gun mounting is to be deposited, the crane will have the duty of lifting the mounting from the pontoon's deck, swinging itself around through a horizontal right angle and lowering the mounting into place. But there is a further requirement. The reach of the crane when securing the load is much less than the reach of 100 feet which it might be called upon to use in depositing. Necessarily, then, the reach has to be changed while the crane has the load. In fact, it is possible for the unloaded crane to set itself at the start at a reach of only 51 feet from its own vertical axis of rotation.

The base of the crane rests on rollers, these rolling in a path or orbit of 25 feet radius. With the addi-

# Succeeding in Safety Engineering

## The Man Who Makes Industry Safe for the Worker, and What He May Hope to Get Out of It

By Raymond Francis Yates

THE author feels that this is one of the most important subjects he has treated in this series. Safety Engineering has to do with saving human lives. What could be more worthy? It is described as "the development and application of engineering ways and means of accident prevention." It is an engineering science that has grow out of our complicated, and in many cases treacherously hazardous, industrial development. It is indeed the science of saving life and limb—it is the application of engineering principles to lessen human misery. It is a great humane movement, which, in spite of its youth, has already saved many a breadwinner for his family.

Mr. H. W. Mowery, President of the American Society of Safety Engineers was kind enough to give the author the data embodied in this article. Mr. Mowery has a big, broad humanitarian version of safety engineering and the writer can feel the tang of his inspiration as he writes these lines. As President of the American Society of Safety Engineers, Mr. Mowery is one of the leading spirits of this work in America. Every day he is putting his heart and soul into the work of spreading the gospel of safety.

We will start this article by considering the service a safety engineer renders his country. First and foremost he is a protector of human life. He also prevents men from being maimed and crippled. From an economic point of view he protects that portion of the total casualties yearly, causing a waste of approximately $720,000,000, which is preventable by engineering revision.

What education should a safety engineer have? This is somewhat difficult to answer. It is not only education that is necessary for a successful safety engineer. The personal factor enters into this matter. There are certain personal qualities that contribute to the success of a man working in this field. He must be sort of a "human" engineer also, that is he must know how to engineer human beings. He should be amiable, kind-hearted, patient and quick to see things that endanger life and limb. He must possess a pleasing personality. It is no profession for a "grouch."

The purely technical side of a safety engineer's education must be somewhat general. He should be thoroughly grounded in all the fundamentals of engineering. He must have a good technical education gained in college or outside of college, it makes no difference. The man training himself for this work should be fully conscious of his responsibility. He must realize that he is to be a guardian over human life and that his mistakes are very apt to be sad ones. It would seem that any man educating himself with these facts in mind should try to make a good job of it.

A young man may say to himself, How do I know that I have the proper personality to succeed in safety engineering? He can answer himself by asking himself these questions: How many friends have I? Do I get along well with my fellow workers? Do I get along well with my superiors? Am I a good sport? Do I swear and lose my temper when my collar button drops down the back of my neck or under the dresser? The last question is a good test for patience.

The young man reading this article should constantly keep in mind the fact that safety engineering is one of the infants of the engineering profession. It has not yet reached its economic level and the question of salary cannot as yet be clearly defined. Some men receive $2,000 per year while others are receiving as much as $15,000. It is regrettable that the majority of industries are not as yet thoroughly awakened to the value of accident prevention work. Consequently they do not offer salaries that attract men of the type needed in this work. In a general way it can be said that the salary of an expert in safety engineering would be determined by his value to the organization employing him. In other words it will be determined at present by the amount of saving he makes in compensation, hospital, medical and other direct and indirect losses. Of course the lower these expenditures are the lower will be the number of accident occurring in the factory.

Mr. Mowery informed the author that as yet many safety engineers have not gone into business for themselves. In the same breath he also mentioned that this was probably because of the fact that there are not many real safety engineers. The profession is developing rapidly but at present most of its followers are employed by State labor departments, insurance companies and large industrial organizations. There is a great opportunity for safety engineers to go into business for themselves and provide service for a clientele made up of the smaller plants.

Unfortunately our colleges have not yet recognized safety engineering in their courses. An effort is being made to have the fundamentals of safety engineering incorporated in existing technical courses and a special course created that will officially authenticate those who qualify as safety engineers. The American Society of Safety Engineers is now considering the formulation of a curriculum for the education of safety engineers.

The present demand for men trained in safety engineering is far in excess of the supply. Mr. Mowery believes that it will be for many years to come. It will surprise many to know that thirty-nine States of the Union have some form of Workmens' Compensation Law. The demand has grown rapidly as a result of the urge from State labor departments, insurance companies, etc., to safeguard employes. At present, most of the recommendations are made by inspectors from insurance companies and State departments. The employer will eventually call in a safety engineer to cure unsafe conditions in his plant just as he would call in a physician to cure any unwholesome conditions of his body. There are several companies which make a specialty of providing such services to industrial establishments.

It seems that there is no great demand for specialists in safety engineering. It may be that a man may become better qualified, through experience, to handle electrical hazards than other kinds. Another man may specialize on hazards in chemical industries, another in railroad work, etc. In general it can be said that a safety engineer should be capable of intelligently handling any kind of hazards. The author asked Mr. Mowery how long a man should train himself to become a thoroughly capable safety engineer. He said that everything depended upon the man, and added: "One cannot expect to master the fundamentals of engineering, and of safety engineering in particular, by listening to a course of a dozen lectures, and while I am certainly disposed to approve the custom of holding night schools for foremen, giving them condensed interesting talks on safety of a nature to bring about their coöperation, however, I surely do not approve of giving them diplomas indicating that they have graduated from a course in safety. It creates a wrong impression in the minds of the men, and serves to lower the standard of safety engineering through possible misunderstanding. Recently a foreman, having graduated from such a course, advertised for a position as safety engineer, describing himself a 'good mixer.'

"The idea that I have had in mind for years, and which I think it would be well for every safety engineer to have, is, 'to make material conditions so safe that a person may pursue in safety his normal activities without abnormal care.' I believe that educational activities and general propaganda are vital to the spread of the gospel of accident prevention, but I believe that actually to prevent the accidents the material conditions must be made safe. People—whether educated in safety practices or not—at least will not be injured by a hazard removed.

"That there will hereafter be some form of safety engineering is sure. But whether the activities directed to prevention of accidents will be continued by lawyers, doctors, favored nephews, foremen, etc., or by members of the various safety engineering professions becoming inoculated with the safety idea so thoroughly that they will incorporate it in all of their work, thinking of safety in preference to the activities whereby they have gained their distinguishing name; or whether it will be necessary to establish another branch of engineering to be known as 'Safety Engineering' remains to be seen. I am inclined to be of the opinion that safety engineering as a profession, to cure conditions that are causing the present great waste in life and property, is surely developing. I believe the safety engineer's work is becoming clearly defined and he need make no apology or abject pleading for his profession. In a single plant, he has reduced the casualty cost of $35,000 per year, in 5 years' effort to $4.500 per year. But it is unreasonable to expect mechanical, electrical, or any other type of engineers to do other than stress those phases of engineering through the practice of which they have obtained and retain their distinguishing name. They will not stress safety engineering any more than will a physician or a dentist. A certain type of engineer strives to create something in his particular line. He views his work from that angle. If it is a means of production, a safety engineer will be called in for he will look at it from an entirely different angle, namely, safety to life and limb rather than quantity or speed of production. He sees that it is safe; that is his duty, his profession."

There is great opportunity for a display of genius in the safety engineering field. Already the patent office has granted a large number of patents dealing with safety devices. We are at the dawn of the safety age. Safety engineering is not only the application of engineering principles to life protection, but also the science of developing and perfecting additional devices that make dangerous industrial operations safe. The well-known punch press is an instance of safety engineering applied to dangerous machines. A few years ago the punch press was responsible for the loss of a great number of hands and fingers yearly. Along came the safety engineer and today these presses are "muzzled" and with reasonable care on the part of the operator there is not much excuse for accidents. If the hand is under the die when the press is tripped the ram will come down a certain distance and stop.

The safety engineer has encased belts, covered gear wheels, made men wear goggles, put spikes in the ends of ladders, illuminated dark places, made men cut sleeves off short when working around machinery, put railings where they were needed, improved insulations, ventilated our factories—and these with many other things he has done in such a way that their doing has actually been financially profitable to the employer.

Nothing must escape the keen eye of the safety engineer. There are two things he must keep constanly in mind. First and foremost is the saving of life and limb. Then, too, he must remember that this is to be done with a minimum sacrifice of efficiency. In most instances there is absolutely no sacrifice of efficiency, and, in some cases, there is an actual gain in efficiency through the introduction of safety methods. When a workman feels that he is protected it instills confidence in him and he may work faster without keeping his mind on protecting himself.

*EVERYBODY who works with his hands knows that today there is a great deal more attention paid to means for helping him avoid accidents than there was some years ago; and everybody who reads knows that there is a lot more talk about this sort of thing than ever before. But perhaps everybody does not know that the effort to make industry safe for the workers has given rise to a new profession. In the beginning, doubtless, it was left to the mechanical engineer to make machinery safe, and to the electrical engineer to make electrical apparatus safe, and similarly in other fields. Today, however, it is found that with one man to attend to all this, to co-ordinate the work in the various fields, and to bring the legislative and medical angles of the proposition into harmony with the practical, the results are so vastly improved that the safety engineer amply justifies his existence. In this article Mr. Yates considers the further point of whether the opportunities in this field justify a young man in making it his profession.*

# Names That Live in Our Language

## Some of the Men Whose Exploits Are Commemorated by Nouns and Adjectives

By D. Waterson

THE desire to be remembered or to have our dead remembered has existed since the world began. Thousands of human-built memorials have long ago crumbled to dust, but mountain and river, tree and flower, state and town and mineral perennially perpetuate a name, though the bearer and that which he did are but dimly recalled except by the erudite. *Pike's* Peak, the river *Livingstone*, *Douglas* pine, *Dahlia* blossom, *Pennsylvania*, *Carnotite*, etc., are memorials of worthy men.

Some names have passed into everyday speech, some are adjectives, every great discovery or international crisis erects another mental monument, especially war, though, after a time, many perish altogether and the others require a biographical dictionary for elucidation.

It would be particularly puzzling to decide which of the proper names that have entered into the current slang and semi-slang of the day will and which will not survive. Merkle and Dr. Cook as symbols of utter stupidity and fraudulent claims have been crowded out by the latest sporting idiom, which refers to knock-outs and home runs as Jack Dempseys and Babe Ruths; will these terms, too, pass along with the bearers of the names which they commemorate, or will they become a lasting part of the language? The answer to this query is perhaps less doubtful in the case of scientists and inventors than in that of sporting idols and nine-day occupants of the front page of sensationalism; but there must always be some doubt. Nevertheless, a great multitude of such terms survive in the body of unquestioned English.

Particularly striking is the large group of memorial names in the electric and radioactive world; I have grouped a few together to interest those who constantly use the terms yet do not know their derivation:

The measurement for pressure or electromotive force is a *volt* named after Alessandro Volta (1745-1827), an Italian physicist, originator of the electrophore, electroscope and the Voltaic pile and who proved Galvani (*galvanize*) wrong in his theory of animal magnetism. The student reads that the *ampère* unit of electricity gives the rate of flow, i. e. it takes one *volt* of pressure to drive a current of one *ampère* strength through a resistance of one *ohm*, but he does not gain the additional interest of knowing that André Marie Ampère (1775-1836) was a French electrician and "the father of electro-dynamics," who found that two parallel conducting wires attract each other when the current traverses them in the same direction but repel each other when the current flows in opposite directions. George Simon Ohm (1789-1854), a German physicist, claims the *ohm* law that the electromotive force divided by the resistance is equal to the strength of the current.

The *watt* is one *volt* multiplied by one *ampère*, but James Watt (1736-1819), inventor of the condensing steam engine and his work is generally known. The unit was too small to be convenient, so electricians adopted 1,000 watts as a commercial unit of power and named this a *kilowatt*.

The *coulomb* brings into view Charles Auguste de Coulomb, a French scientist (1736-1806), who invented the torsion balance, which gave two new inverse square laws in addition to the Newtonian one of gravitation. A *coulomb* is the quantity of electricity required to produce a definite chemical effect—to deposit 1.1183 milligrams of silver.

And a *mache?* It was a German physicist, Heinrich Mache, still living, and his co-worker, St. Mayer, who hold this unitary honor, the unit representing the quantity of radium emanation, without disintegration products, which produces a current of limited saturation.

The *joule* is named after James Prescott Joule (1818-1889) of Manchester, England, the unit being the energy expended in one second by a current of one *ampère* passing through a resistance of one *ohm*.

It is hardly necessary to mention the origin of the *Curie* unit which represents the quantity or mass of radium emanation in equilibrium with one milligram and one-thousandth of a milligram respectively, for Marie Curie is still working, though Pierre Curie is dead. She was greatly pleased when the Radiology Congress in Brussels, 1910, determined on the name in memory of the splendid work achieved by the Curies.

I have chosen but one little group, but enumeration of all would take a long article. The *farad* unit (Michael Faraday, 1791-1867) from which faradization comes, could be added, and most readers know of *mesmeric* powers and of being *mesmerized* (Franz Mesmer, 1773-1815).

*Galvanic*, *galvanized* are equally familiar. Luigi Galvani (1737-1796) was a professor of anatomy at Bologna and was noted for his investigations in the contractions produced in the muscles of frogs by contact with metals. This was the beginning of galvanic or voltaic electricity.

There are dozens of names which are used as adjectives: *Hertzian* waves, *röntgen* rays, *coolidge* tube, and, to step a little outside the scientific world, who does not enjoy having a *mackintosh* in winter and the smooth *macadamized* roads? Charles Mackintosh, the Englishman who, in 1823, found he could apply naphtha to cloth and so render it rain-proof, was also doubtless pleased, and John Macadam (1756-1836) certainly found the English roads in a horrible condition when he brought his engineering skill to work on them, France quickly adopting his theories. Another "Mac," this time Macassar, invented a wonderful hair oil early in the 19th century, which was so freely used and the oiled heads so bad for stuffed furniture that "anti-Macassars" came into general use. When Sir Robert Peel instituted the London police force, they were and are known as "Peelers" or "Bobbies."

Some men's characters are perpetuated as uncomplimentary adjectives. All know the *Judas* kiss, a *Macchiavellian* policy (Nicolo Macchiavelli, 1469-1527); and Louis Daguerre (1789-1851), who belonged to the French Internal Revenue Service and who afterwards, with Niépce, invented photographing on metal, had such a reputation for indecision and unreliability that anyone possessing the same faults was spoken of as a mere daguerreotype, or shadow of a man.

It is seen then, that some names will be used forever as terms of honor or dishonor even though the owner as an individual is forgotten. Even today how much does the average person, reading advertisements, know of what splendid achievements and benefits *listerized* gum and *pasteurized* milk remind the man who has read of Lord Lister and Louis Pasteur?

### Ventilation of the Hudson River Tunnel

To the Editor of the SCIENTIFIC AMERICAN:

That the construction and completion of the tunnels under the Hudson River at Canal Street, intended for vehicle traffic will be a great convenience is proven by the daily congestion at the ferry entrances on both sides of the river. Along with their urgency there is the great importance of proper and ample ventilation without which the tunnels would be useless. The greater number of vehicles, probably 90 per cent of them, will be automobiles and motor trucks, exhaling poisonous gases. On this point the *Literary Digest* for August contains a very instructive article. It concludes with the warning that the contents of carbon monoxide (the most poisonous gas contained in the exhalations of motor vehicles) must not exceed the maximum of four parts in ten thousand parts of air. This conclusion has the endorsement of the United States Bureau of Mines, but the solution of the problem is left entirely to the engineering department of the Commission.

Although a novel problem, the principle of it is simple and easily understood. Fresh air is conducted through a duct the entire length of the tunnel from which holes short distances apart admit the air to stream into the tunnel and dilute the poisonous gases. Another duct, also running the entire length of the tunnel and also connecting with the tunnel through numerous holes, sucks up the contaminated air which is expelled through shafts at each end by mechanical blowers. The ventilation is therefore crosswise of the tunnel and a continuous operation which requires careful designing for its success.

Let us believe that the engineers of the Commission have thoroughly studied the problem, yet it is of such overwhelming importance that the details of that study should be published as proof thereof.

To mention only one point. The velocity of air and gases through the ducts will be very great. The friction along the walls of the duct and through the orifices will consume a great deal of power, which will increase rapidly as the walls of the ducts will become incrustated from the dirt and oily particles in the air. The surface of the ducts will therefore require periodic inspection and cleaning similarly as chimneys require cleaning from soot. To that end the height of the ducts should be sufficient for a man to walk through from end to end, 8,000 feet long. But the height in the plans is only 4 feet 8 inches for lower duct and about 5 feet in upper duct. These heights are too low and would require continuous stooping of the workmen, which is both exhausting and tormenting in long, hot ducts.

Ordinary foresight also requires that in the lower duct provision be made for carrying off the dirt on some narrow gage railway. The upper grating seems hardly strong enough to bear the weight of men.

The clear height of tunnel is only 13½ feet, while the minimum of clearance on our streets under the elevated structure is 14 feet. From all this it appears that the diameter of 29 feet should be increased at least to 32 feet.

No short-sighted economy should expose the users of the tunnel to poisoning by insufficient ventilation. On this point the details cannot be too specific and should be published. The Commission would assume a great responsibility in ignoring this justifiable demand.

MECHANICAL ENGINEER.

### Some Questionable Botany

To the Editor of the SCIENTIFIC AMERICAN:

May I call your attention to some rather unfortunate terms employed and statements made in the article on page 651 of your issue of June 12th?

In the first paragraph we have reference to the "progress in artificial fertilization of seeds." Without comment on the rather unimportant fact that seeds are not fertilized, because of the ovules which are present in the ovary of the flower cannot develop into seeds until they have been fertilized, I want to call attention to the fact that it is not artificial fertilization but artificial pollination which the plant breeder practices. That paragraph and the next contain several loose statements which I pass over lest I seem pedantic; but it is impossible to ignore the sentence reading "As our photographs show, this operation (artificial pollination) consists in elevating the anthers of the flower to be fertilized, then in depositing upon these the pollen of the fertilizing variety." The pollen, of course, is deposited upon the stigma of the pistil, not upon the anther of the stamen.

While I am at it I wish to comment on the letter published on page 645 of the June 12th issue and signed by Homer J. Carleton of Los Angeles. The letter refers to "earth preserved eggs" which Mr. Carleton reports having been offered for sale at Pasig, P. I.

I feel sure that Mr. Carleton must be mistaken in his belief that these eggs were in any way similar to "the ripened eggs of the Chinese." The eggs of which the Tagalog of the provinces near Manila are so fond and which are called facetiously by the Americans "chicken on the half-shell" are, as a matter of fact, not eggs but chickens, for they are nothing more than eggs which have been incubated almost to the point of hatching and then boiled. They are called "balut" or "baloot" by the Tagalog, and are peddled at every station along the railroad running from Manila into La Laguna and Batangas provinces.

During three years' residence in Manila and on the shores of Laguna de Bay I have met many Europeans who professed great disgust at the natives who ate "baloot"; but, though I have never been able to carry my philosophy into action I cannot even yet understand why, when eggs are good to eat before hatching and chickens good to eat after hatching, eggs should not be good food while they are being hatched into chickens!

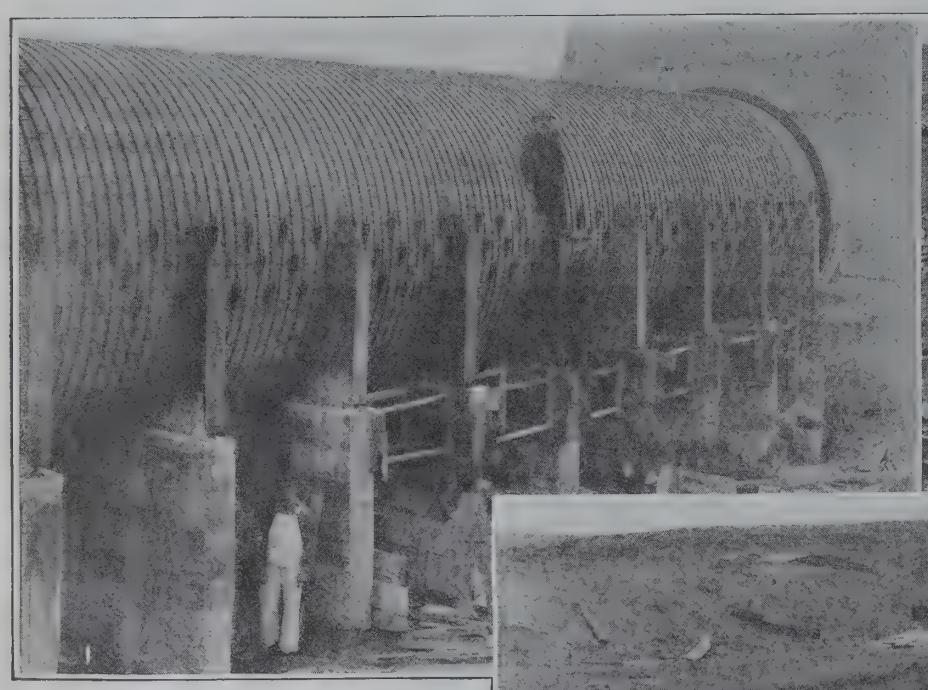
[PROF.] RICHARD M. HOLMAN.

Crawfordsville, Ind.

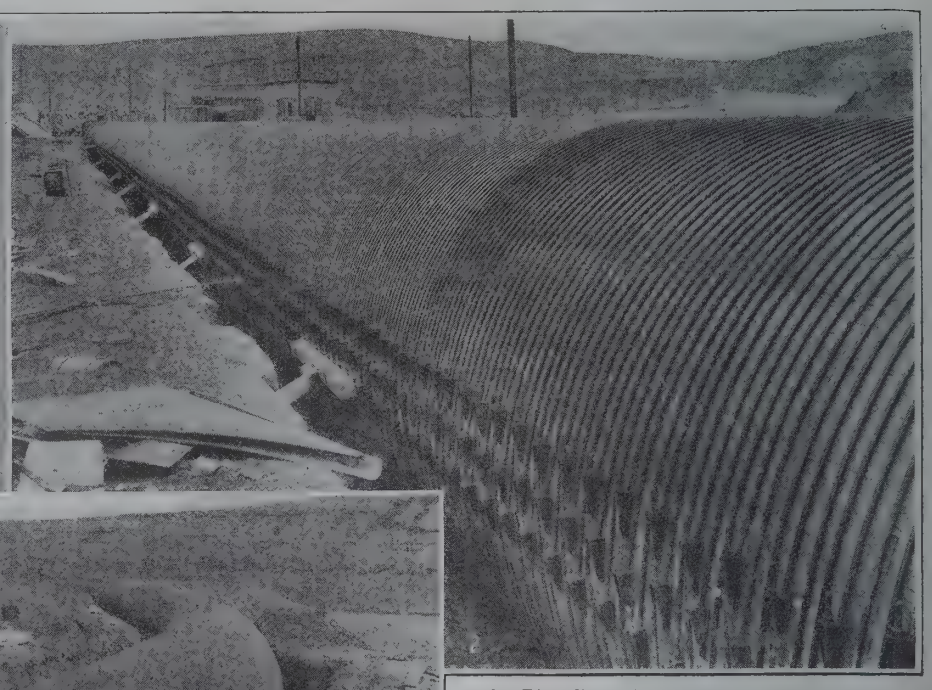
# Water Pipes of Wood

## The Surprising Permanence and Tightness of This Unusual Construction

By J. F. Springer



1. Exposed pipe laid on foundation of concrete wings.



2. Pipe line which will lie partly covered and partly exposed.

3. One of California's biggest pipe lines is of wood.

**Water pipes of wooden staves with hoops of steel**

MANY persons who have not kept in touch with engineering developments of the past few years will perhaps be surprised to learn that wood stave pipe has come into use for the transport over long distances of large quantities of water and the like. Wood, to many of us, seems ill-adapted for out-door service, if long life is to be required. And yet, wooden piles have for a great many years been considered as thoroughly dependable. This is especially the case where the entire pile is well submerged below the water line. Such piles have been taken up after long service and found to be in just about as good condition as when put down. With facts of this description in mind, we shall perhaps be better prepared to understand the use of wood stave pipe in important engineering undertakings.

One of the early instances of an important wood stave pipe line is the semi-cylindrical half-pipe or flume laid in Utah in 1893. The diameter here was 48 inches. The water carried varied considerably in quantity. The maximum head was 70 feet. The whole of the flume was above ground and part of the line was exposed to the full heat of the sun on one side. When 31 years old, this pipe was inspected and the wood found to be undecayed. A sugar factory in California built in 1902 had wood stave pipe for discharge purposes. However, this pipe was in service 4 months of the year and idle 8 months. The engineer concerned not so long ago thought the pipe would have a life of 50 years. Palo Alto, California, near San Francisco Bay, has a sewer of wood stave pipe which runs across the salt marshes on the coast. This line is in part fully buried, in part half buried, and in part completely exposed. Flood tides cover it, at least in part, and ebb tides leave it exposed. It was said, a year or two ago, to be in perfect condition. In 1900 there was built for the water supply service of San Diego and Coronado, both in California, a total of 7½ miles of wood stave pipe—about one-third being of 40 inches diameter, and the two-thirds of 36 inches. The water pressures vary between those due to a head of 150 feet and a head of 295 feet. For nearly the whole length, the pipe line is buried in alkaline soil, but some short lengths are carried across deep ravines on trestles. In 1916 this line was examined and found to be in excellent condition. In fact, it is claimed that the wood was harder than it was originally. Just about all the foregoing pipes were constructed of redwood timber.

It will be seen from the foregoing that wood staves have been tried out under severe and varying conditions. However, there is wood pipe and wood pipe. Just any kind of wood will not suffice. One of the principal requirements that the material which enters into the body of the pipe must fulfil is that it shall resist decay, even if it is not perpetually saturated. Where constant saturation is to be depended upon, several kinds of wood will answer. In fact, perpetual saturation tends to prolong the life of wood in general. There are, however, other considerations which wood pipe must generally fulfil, and these tend to cut down the possible kinds of wood. Redwood, fir, cypress and pine are all in actual use for wood pipe. It is claimed that pitchy woods, like fir and pine, will not last under conditions of partial saturation. The pitch is cited along with the sap as having a tendency to produce deterioration, even if there is saturation. On the other hand, the Canadians have constructed a continuous wood stave pipe line, 8 feet in diameter, of British Columbia fir. This is a good big fellow and indicates Canada's faith in Canadian wood. An American engineer specializing in wood pipe says that fir and pine will, under certain conditions, have a long life and give perfect satisfaction. Thus, if the climate is dry, either wood may be expected to do well, if the erection is such that a circulation of air obtains all round the pipe. Heavy pressure of the contained water when combined with imbedment in compact soil promotes long life. Pressure water is good because pressure produces saturation or tends to do so. Redwood and cypress are said, in some quarters, to be about the only commercial woods suited for alternations of wet and dry climatic conditions. Cypress is, however, said to be becoming more and more unobtainable, except at a price. Apparently, there exist only a few cypress pipes.

Redwood is claimed as really the best commercial wood for pipes and as surpassed only by cast iron in respect to length of life. There seems to be a peculiar constituent of this wood of an acid character. It is of importance as it preserves the fiber against destruction by micro-organisms.

In building wood stave pipe lines, the engineer must be content generally to let cost have serious weight. He will generally have to take some middle course. Thus, thick staves give the better pipe, and wide staves mean reduced cost of erection. But, a pipe is not necessarily as much better as the staves are thicker. And a wide stave may not result in enough saving in erection to pay for the waste of timber thus brought about. A nominal size of 2 x 6 inches has been put forth as a good size of stock for economical manufacture of staves, all things being considered. The nominal thickness and the nominal width will be cut down somewhat. The stock size given will be suitable for all pipe sizes from 26 to 52 inches. In general, the thickness of the stave will vary with the diameter of the pipe. But other considerations enter.

A wood pipe must favor penetration of the water. But it must not permit excessive percolation. The wood may be dense and hard. This may hinder perfect saturation. Then, the wood may consist of alternate portions of hard and soft material—winter and summer wood—under which circumstances excessive percolation is to be feared. The water will find its way out through the soft material between the regions of hard material. Redwood is a very soft and cellular wood. If the sap has been got out, it is resistive to percolation and favors saturation. However, different staves in the same pipe will often differ in the combination of their resistances to percolation with their facilitation of saturation.

It is considered important in constructing a wood stave pipe line that the staves be quite dry at the time of erection. The reason for this is that then the bands may be cinched tight, and the whole pipe made tight when dry. When such a pipe undergoes in service the experience of having the water drawn off the line, the shrinkage of staves, and the consequent opening up of seams, has been forestalled. Even though there should be some shrinkage and some opening up, the return of the water will produce enough swelling to result in tightness. If wet staves are used, they are already swollen; so that the withdrawal of water from the line will result in excessive changes, changes too great for the returning water to rectify with certainty.

The lumber which goes into a pipe line should, it is asserted, be thoroughly air dried. This is the natural process. Kiln dried lumber is condemned, if the drying is carried out by the older process. There is a newer procedure which employs steam indirectly, and makes use of a circulation of air having a proper temperature and a proper humidity. Under the old kiln process, redwood is said in effect to become flinty and capable of being broken into splinters over the knee.

The engineers having to do with wood pipe have not been altogether in agreement as to the matter of

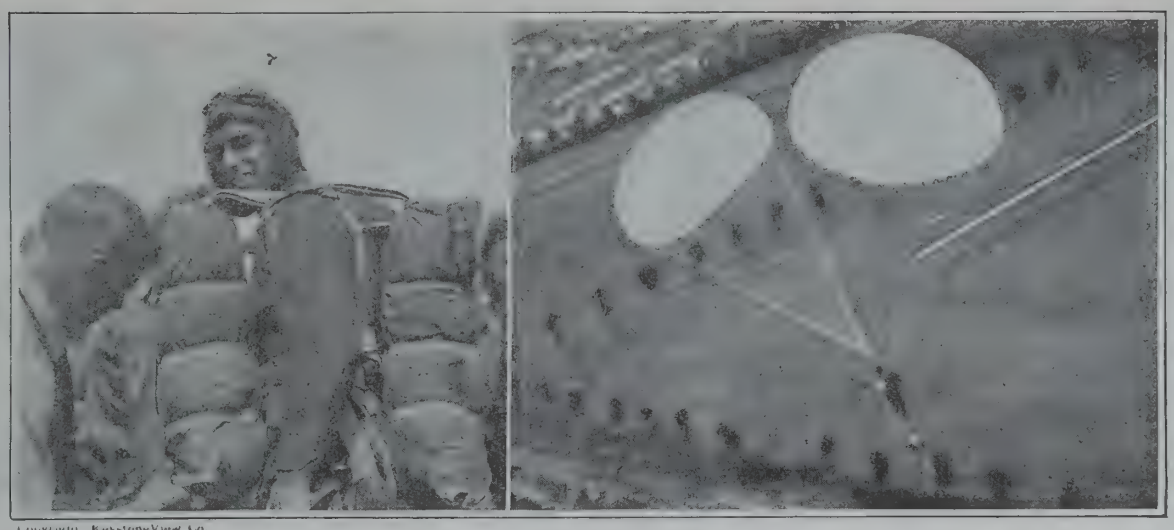
(*Continued on page 262*)

## Making Doubly Sure of the Parachute Jump

AVIATION is getting safer every day. Not only has the airplane been made safer in many different ways, but it is being equipped with parachutes for use in the event of an involuntary descent. And now comes the latest safety device for aerial travelers, namely, the double parachute which makes a parachute descent just twice as safe as with the conventional single parachute.

The United States Aviation Corps has been conducting a series of experiments with the new double parachute. Sergeant Gilbert A. Shoemaker, a veritable daredevil aviator, so we are told, has been using the double parachute with excellent results.

It appears that this device can be used either single or double at a time. If one parachute fails to open, which sometimes happens, the other by all the rules of probability should open. Again, if the descent is too rapid, the second parachute can be opened so as to lessen the rate of drop. The accompanying views show how the double parachute is worn by the aerial traveler and how it functions during a big drop of several thousand feet.



Copyright, KeystoneView Co.

**The double parachute worn by Sergeant Shoemaker, U.S.A., and how it opens up in a 5,000-foot parachute jump**

## Towing a Ship Across the Pacific

WHEN the tug "Hercules" on April 9th steamed into the harbor of Vancouver, Canada, towing the five-masted auxiliary schooner "Laura Whalen," a new Pacific Ocean towing record was established, one not nearly approached in many years in marine annals. The "Hercules" brought the schooner from the port of Papeete, Tahiti, in the South Seas, a total towing distance of 4,630 miles.

The "Laura Whalen" is one of a dozen five-masted schooners built of British Columbia fir which were constructed during the war specially designed as wheat and lumber carriers. Sailing on her maiden voyage on April 25th, 1918, a long series of disasters attended the ship. Lastly, after crew desertion, much engine trouble, she put into Papeete a few months ago with her rigging almost stripped, damaged engines and a ruined cargo of tallow, wheat and hides. The tallow had been carried as a deck load. Some of the casks became broached by storm. The hot South Sea sun melted the tallow which ran into the hold and mingled with the wheat. Having discharged her cargo and finally been pronounced unseaworthy to carry cargo, the "Laura Whalen," with fifty tons of ballast, was taken in tow on March 3rd by the tug "Hercules" and arrived in Vancouver on April 9th.

## Australia's Railway Gages

APPROVAL has been given to a proposal to give a uniform gage of 4 feet 8½ inches on the railways connecting the capital of the mainland Australian states from Brisbane to Perth. It is estimated that this will cost $120,000,000 of which the Commonwealth is to contribute one-fifth, the five states concerned finding the rest on a per capita basis. The Commonwealth line from Port Augusta to Kalgoorlie, 1,057 miles, which is one of the main links in the connection, is already on the 4 feet 8½-inch gage as are the New South Wales lines. Western Australia would have to convert 375 miles of 3 feet 6-inch line, Victoria 200 miles of 5 feet 3 and South Australia several hundred miles of 5 feet 3 inches, and 3 feet 6 inches, while Queensland would have to build 100 miles of new 4 feet 8½-inch line. It is also proposed to build several hundred miles of new line in New South Wales and South Australia in order to shorten the distance by rail from Brisbane to Perth, now 3,300 miles, by 469 miles. The conversion of the other lines in Australia to the 4 feet 8½-inch gage would be done later in piece-meal fashion. There are 22,046 miles of railway on the mainland of Australia, the proportion in the different gages being 5 feet 3 inches, 5,149 miles; 4 feet 8½ inches, 5,881 miles; 3 feet 6 inches, 10,866 miles; under 3 feet 6 inches, 150 miles. The cost of converting to the 4 feet 8½-inch gage all the lines not provided for in the $120,000,000 scheme recently adopted has not been estimated but would probably amount to $500,000,000.

## Again, the Water Bicycle Races

FRANCE has always been partial to new and odd methods of locomotion. It was France which first fostered the automobile when it was a feeble, balky, uncertain and unpromising thing; France placed her faith in the airplane even before the Wrights gave their practical demonstration of heavier-than-air flying; and now France is playing with water bicycles, winged bicycles and other toys, so to speak—but these are toys which may yet prove practical in the no distant future.

Another water bicycle race has just been held, this time at Enghien, just outside of Paris. As in previous contests of this sort, all kinds of queer contraptions participated in the race. Some contestants used craft driven by airplane propellers, others made use of the usual marine screw, while still others made doubly sure of their locomotion, so it would seem, by using airplane propellers and marine screws in combination. As luck would have it the simplest form of machine won. This machine, No. 5, driven by M. Bernard, won nearly all the races. In fairness to M. Bernard it is well to call attention to the fact that the driver, who must work the pedals as in bicycling, deserves just as much credit as the machine, if not more so.

The pedals of the water bicycle serve to drive the propeller or propellers, while the handle bars operate one or two rudders for steering purposes.

**This modified form of canoe, equipped with 15-horse-power engine, makes 25 miles per hour**

## Thermometer Deterioration

EVEN thermometers become old, and consequently inaccurate with age, mercurial instruments reading too high and spirit instruments too low. In the former case the bulb appears to shrink, thus forcing the quicksilver too far up the stem. This gradual shrinkage is supposed to be due to the fact that the external pressure on the bulb may be considerably higher than the internal pressure, the air as far as possible having been removed before the glass is sealed off. On the other hand, the spirit thermometer is sealed with the bulb covered in a freezing mixture, in order to lock up in the glass as much air as possible. The instrument thus starts with an internal pressure which in time appears to be reduced either by expansion of the glass under the internal pressure or by leakage.

## Turning the Canoe Into a Speedy Power Boat

EVERYONE is more or less familiar with the speed and easy-going characteristics of the canoe. And everyone has at some time or other come across the engine-driven canoe—generally a canoe equipped with a small gasoline engine of one-half to two horse-power. Now comes William H. Wray of Brooklyn, N. Y., with a modified form of canoe which he has equipped with a 15-horse-power twin-cylinder motorcycle engine. This odd power boat is sixteen feet long and carries three passengers. The engine drives the propeller by means of a chain. A speed of 25 miles per hour can be readily maintained.

## Technical Sponges

A SPONGE can be briefly defined as the skeleton of certain aquatic animals—naturally there are a number of varieties. This skeleton while being fairly strong when first used, gradually softens and breaks down through use and bacterial action. A patent for a tanning process has recently been issued to W. H. Allen of Detroit whereby the strength of the sponge is greatly increased and also increased resistance to bacterial action. The sponge is chemically in the same class of material as hides, and we know the lasting qualities of good tanned leather; therefore, it is to be inferred there is a good fortune for the tanned sponge.

**Where New York's gas meters are proved to be accurate before they go into use**

# Checking Up the Gas Meter

## How New York's Consumers Are Assured That They Get What They Pay For and No More

By William R. Andrews

IN New York City about four thousand new and used gas meters are tested each week for accuracy, first by the gas company, then by inspectors in the employ of the Public Service Commission. The result of one test made not long ago showed a general average in favor of the consumer by 1.79 per cent. A similar low percentage became evident in the tests of 59,475 meters made by the Massachusetts Gas and Electric Light Commissioners. The figures of the Board revealed the fact that only 206 of these meters were inaccurate. A few were fast, and those that registered slow were found to average 3.78 per cent over the average of the fast meters. Here again the results favored the consumer.

The gain by the public through such percentages as these is due to legislative enactment in the various States where commissioners have been appointed to supervise the relations between public utilities and the consumer of gas, water and electricity. For instance, in New York State gas meters are not allowed to run over one-half of one per cent fast, a trifling gain for the companies. The net result is so small that the tolerance may be compared to the one-eighth of an inch variation in a mile allowed a civil engineer in running a line for railroad trackage. It is pretty evident that the "gain" is almost infinitesimal in both instances. But there is still another factor to be reckoned with—the commission permits a meter to run two per cent slow. Thus the consumer whose meter fails to register correctly in this particular is the gainer, and by legal cognizance. If on test this discrepancy in the action of the meter is found the gas company cannot collect arrears. On the other hand a rebate is allowed if tests show a meter has been running fast.

Notwithstanding the advantage to the consumer in the few instances of meter variation in his favor, the law governing such cases was not passed with any idea of favoritism. The purpose was to meet the exigencies of certain mechanical contingencies which might affect the equitable distribution and sale of the company's product and its payment.

Curiously enough these statutes safeguard the consumer in a way he little realizes. The ancient law of *caveat emptor*, which governs the purchase of practically everything except electricity from a public utility corporation, seems to have become inoperative in his case. For, as gas is standardized in quality and fixed in price by law, he does not, when dealing with a gas company, buy at his own risk. As to electricity, the parallel applies only to the price-fixing by public service commissions. Everyone knows, of course, that there is no such thing as a possible variation in "quality."

All meter tests in New York City are conducted in the meter and appliance repair shops of the gas company at 111th Street and First Avenue. The building is 100 by 200 feet and is ten stories high. The meter department however occupies only three floors. The rest of the premises is used for general repair work, the storage of material and the testing of gas appliances—stoves, heaters, ranges, etc.

The overhauling of 4,000 meters a week is no slight undertaking and the cost of the meter tests is borne solely by the company. A considerable force of workmen is maintained and the burden of expense is not lessened in these days of plutocratic labor when an experienced meter tester draws a wage of $60 a week.

Meters to be tested or in need of repair are first sent to the central collection stations of the districts in which the company has divided the city. Thence the meters go to the 111th Street building and are sent upstairs to the testing department on trundle trucks in lots of 200 or less. There are eighteen sizes, ranging from the three-light meter to those which measure the gas consumed by 300 burners. Only a small portion of the meters received are sent to be tested at the instance of the consumer. The majority have been taken from apartments, private dwellings, stores, office buildings, shops and places of amusement in accordance with a prescribed routine. Experience shows that the wear and tear on the mechanism makes it necessary to remove a meter for repairs after six years' service. The overhauling and testing operations number thirty-two and cover a period of three weeks.

For the initial test an instrument called a meter prover is used. This consists of a large metal tank, filled with water, three and a half feet in diameter and about as high as a man's armpits. A cylinder of galvanized iron is suspended with a counterweight from a wheel at the top of a metal frame secured to the rim of the tank. The upper part of the apparatus towers considerably over one's head. Thermometers, a syphon pressure gage and a hose are the principal parts of the equipment. The gage is used to detect leaks, and a vertical metal scale on the cylinder shows any deviation in the meter's registering device when the gas used in the test moves the cylinder up and down in the water.

Besides these machines there are in use on the same floor several automatic provers invented by Marshal Cornine, the superintendent of the meter and appliance shop, and installed about 12 years ago. His invention saves considerable time. For instance: The tangent connected with the top dial over the indices on the front of a meter is set to make one complete turn to register two cubic feet in the tests. On the old style machines the tangent must be run twelve times. But the same result is obtained on a Cornine prover with one revolution of the tangent. The automatic provers are used for the smaller meters and the other type for the large sizes. All the provers are inspected by Public Service experts, who place the seal of the commission on each prover as it is shown to be correct in its operations.

A complete record is kept of every meter brought to

## America's Bid for the Gordon Bennett Cup

**By Austin C. Lescarboura**

AFTER all is said and done, it is the spectacular side of aviation that appeals to all of us—at least to all of us who are interested onlookers; for the aeronautical engineer and the man who has invested his money in winged travel are interested in a collection of facts and figures which mean little if anything to us. The greatest altitude, the fastest flight, the longest sustained flight—these achievements represent to the layman the momentary status of aviation.

So, speaking in the layman's language, we are to have an exposition of what has been accomplished in airplane design and construction during the past decade or so. The great international race for the Gordon Bennett Cup is to be staged in France on September 27th, and there is little doubt that the world at large will be astounded at the bursts of speed of many of the contending machines. It is only a short while ago that the first aerial meet was held at Rheims, where, on August 29th, 1909, Glenn H. Curtiss, piloting a Curtiss biplane with a 50-horse-power engine, beat the Frenchman, Bleriot, by six seconds over a twenty-kilometer course. He had traveled at a rate of 46.5 miles an hour.

In the coming contest no machine which cannot attain a speed well over 200 miles an hour need be entered. It would be ludicrous to enter such a "slow" machine. Again, it seems that any machine with less than 250 horse-power has no place in this coming race; indeed, we shall no doubt witness machines with as high as 600 horse-power engines participating. It has been rumored that some of the European contestants may employ engines of 1,000 horse-power!

The race is to be held at Etampes, near Paris, over a circuit course of 300 kilometers (about 180 miles). The start and finish will be at Etampes. Many monetary prizes are offered, aside from the Gordon Bennett Cup, which goes to the victor. Great Britain, France, Italy and the United States are among the twelve entries. While Germany is barred from this contest, it is rumored that German aircraft constructors have entered several of their machines through the neutral countries, most likely Holland, Denmark and Sweden. One feature of this great race is that pilots may use their own fuel. Thus it becomes possible for the contestants to resort to various synthetic fuels which have been developed for aviation purposes. It is understood that the Dayton-Wright machine will use synthetic fuel. Again, supercharger equipment is permitted, and no doubt more than one contestant will make use of this latest device for ensuring maximum engine efficiency. Hence this race becomes a real and fair test of the machine, the engine and the fuel, as well as the pilot.

Three machines have been entered by the United States for the great race. Two of the three machines are monoplanes, while the third, the Army Air Service entry, is a biplane. All three machines have been designed around some particular engine instead of the usual practice of fitting the power plant to the plane. And each machine has made better than 200 miles an hour in test flights, which speaks well for America's chances of winning the much coveted trophy.

First of all, let us consider the Curtiss monoplane. Here is a machine which is every inch a racer. The pilot's seat is far in the rear part of the body, as will be noted in the accompanying illustration. In fact, it is two-thirds of the distance from the nose to the tail. The monoplane is provided with a short and stubby propeller with stream-lined hub or "pot." The wing is very thick, and is braced on each side of the body by a single thick strut slanting down to the hub of the landing wheel. The radiator is arranged on either side of the body as shown, so as to reduce the head resistance to a minimum. The engine is a twelve-cylinder Curtiss type, developing 400 horse-power.

**The Curtiss monoplane racer, equipped with 400-horse-power engine. Note the position of the cockpit, two-thirds the distance back from nose to tail. Also note the radiator on the sides, so as to reduce head resistance**

### TABLOID HISTORY OF THE GORDON BENNETT CUP CONTESTS

**1909—Glenn H. Curtiss (American), winner. Race held at Rheims, France. Speed attained, 43 miles an hour. Curtiss biplane, 50-horse-power.**

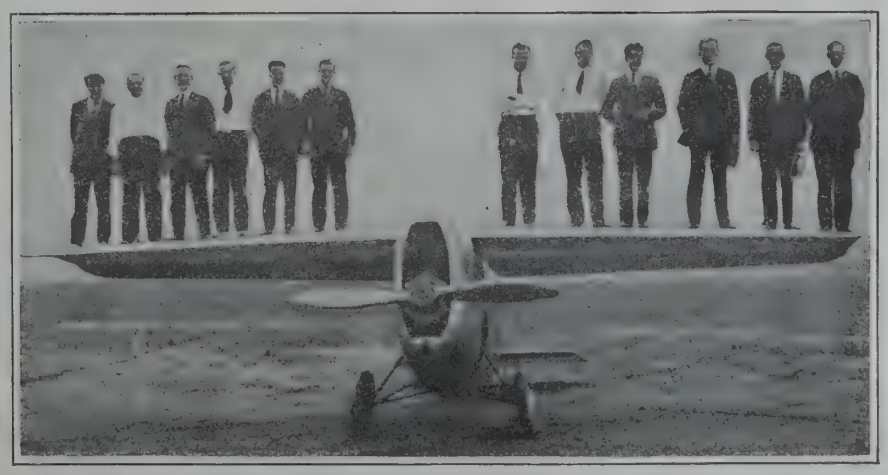
**1910—Grahame-White (British), winner. Race held at Belmont Park, Long Island, U. S. A. Speed attained, 61 miles an hour. Bleriot monoplane, 100-horse-power.**

**1911—C. T. Weymann (American), winner. Race held at Isle of Sheppy, Eastchurch, England. Speed attained, 78.1 miles an hour. Nieuport monoplane, 70-horse-power.**

**1912—Jules Vedrines (French), winner. Race held at Clearing, Illinois, U. S. A. Speed attained, 105 miles an hour. Deperdussin monoplane, 160-horse-power.**

**1913—M. Prevost (French), winner. Race held in France. Speed attained, 126.59 miles an hour. Deperdussin monoplane, 200-horse-power.**

**The Verville-Packard biplane, equipped with 500-horse-power engine. Unlike the Curtiss monoplane, the pilot here is pretty well shut in. This machine has the latest Packard engine which develops unusual power**



**The Dayton-Wright monoplane, equipped with 250-horse-power engine. The wings are rigid cantilever structure, made up of three-ply veneer. The landing gear can be pocketed on either side of the body**

This Curtiss monoplane is being entered by S. E. J. Cox, president of a Texas oil company, and millionaire sportsman. It is known as the "Texas Wildcat." In a recent test flight the machine developed 223 miles an hour, breaking the world's speed record by a safe margin. The monoplane has been built in duplicate, so that if anything happens to the first machine the second will be used. Roland Rohlfs and Clarence Coombs, record-holding aviators, will pilot the Cox planes in the cup race.

The Army Air Service is known as the Verville-Packard and is of all-American design and manufacture throughout. It was designed and built by the Packard Motor Car Company under the guidance of Col. J. G. Vincent, who also designed the engine. [A complete description of the 500-horse-power engine installed in this plane was described in our issue of September 4th, 1920, on page 226.] The engine has a total piston displacement of over 2,000 cubic inches and weighs approximately 1.94 pounds per horse-power, representing a distinct forward step in aircraft power plants.

The Verville plane was designed and constructed especially for this engine, but it is, however, in no way a freak racing machine. It is built for both service and production. The plane itself has been developed by the engineers of the office of the Chief of Air Service at the Engineering Division at McCook Field. It is felt by the Army men that in the face of the terrific speeds which will undoubtedly be shown by all planes entered in this year's event, the Army Air Service has an excellent chance to win. Captain Rudolph Schroeder, present holder of the world's altitude record, will pilot the Army plane.

The Dayton-Wright monoplane measures only 22½ feet from wing tip to wing tip. Its body is 12 feet long. The wings are of rigid cantilever construction. Instead of being covered with fabric, they are made of three-ply veneer. When the little machine is in flight the wheels and the entire landing gear are drawn up inside the body and the machine presents the appearance of a gigantic steel projectile darting through space at more than three miles a minute.

It is this retractible chassis, or landing gear, wing structure, and what is known as a variable camber or wing curve that make the Dayton-Wright a remarkable contestant for world speed honors. While technical details have necessarily been withheld, pending the race, it is known that a crank in the instrument board of the machine enables the pilot, after he has left the ground, to raise the wheels and landing frame into the fuselage, and at the same time using the same mechanism, automatically to flatten out the wing. The whole process requires only from 12 to 15 seconds. It requires even less time to drop the wheels and restore the wing curve in landing.

The curve in an airplane wing affects the speed at which the machine takes off or lands, but it also retards or accelerates its speed while in the air. For instance, the curve of the wing enables it to take off more quickly and land at slower speed, thus requiring a smaller field and eliminating danger in landing in an emergency. By evolving a means whereby the wing curvature can be altered at will, the Dayton-Wright designers have been able to decrease the landing speed to twenty miles an hour, and increase the racing speed in the same ratio.

By drawing up the landing gear and

# The Service of the Chemist

*A Department Devoted to Progress in the Field of Applied Chemistry*

Conducted by H. E. HOWE, Chemical Engineer

## Radium in Medicine

IF purchases can be taken as an indication, it would seem that medical men are approaching unanimity of opinion with reference to the use of radium, which at one time was held to be without value by at least one important group. Recent purchases of $120,000 worth of the rare element by medical men in a single month indicate the tendency and emphasize the necessity of conservation.

It is estimated that there have been between 105 and 110 grams of radium recovered from the ore thus far, of which 70 grams were from American ores. The European reserve stocks were practically exhausted for war purposes, being used principally for luminous dials and elsewhere in forms which mean its absolute loss to science. There are probably between 20 and 22 grams in the United States at the present time, part of which is that owned by the Bureau of Mines and loaned for medicinal purposes. The necessity for conservation becomes more evident when it is understood that the ore bearing the radium occurs in pockets, that the surface pockets have been practically exhausted, and that future supplies must come for the most part from those pockets which can be located by drilling. It is evident that this carries a considerable degree of uncertainty and while authorities differ as to the amount of radium that will possibly be recovered from now on, conservative estimators place it at a total of 100 grams.

## American Analytical Balances

A CONSIDERABLE percentage of the demand for analytical balances is for the type which has a definite sensitivity of one-tenth of a milligram under the full load of 200 grams in each pan. This type of balance has been successfully made by American methods, which means quantity production. One of the well-known manufacturers believed he could effect certain improvements if it were possible for him to obtain orders justifying new jigs and tools, and an order for 1,000 from a single progressive dealer was sufficient to guarantee the new work. An order for so many analytical balances of one type was something new in scientific apparatus of this character, but the result has been a moderately priced balance which meets the requirements of industrial chemists and many of the educational institutions.

## Tin Recovery

THE recovery of tin from scrap has engaged the attention of several chemists, especially since the demand for the tetrachloride of tin has been increased by the rapid growth of the use of silk. A new process has just been patented in which the scrap tin is first treated with a strong solution of sodium hydroxide at from 120° to 150°F. in an iron tank lined with graphite or some other material electro-negative to tin. The galvanic action set up between the graphite and the tin accelerates the solution of the tin, and the operation is repeated with various batches of scrap until the bath is rich in tin. The solution is then placed in a second iron tank and bales of scrap tin are suspended in the bath and a current passed. The tank acts as the cathode and the tin becomes the anode. In this process the tin from the bale is dissolved and deposited, while the tin is also deposited from the bath itself, so that it can be returned to the first tank and re-used.

## Graphite from Kish

THE story of how artificial graphite produced from anthracite or petroleum coke by electrolytic methods employing Niagara power has gradually replaced natural graphite, is well known. Natural graphite has held its place principally in the manufacture of large crucibles, but recently patents have been issued covering methods of manufacturing crucibles in which artificial graphite is an important ingredient. The output of artificial graphite has risen very rapidly, and from 1915, when it reached five million pounds, it increased to ten million pounds by 1918. Much of it finds its way into lubricants, paints, battery fillers, foundry facings, and boiler scale preventatives.

Attention has recently been called to the possibility of recovering graphite from the mixture of that substance with slag, iron oxide, fragments of iron, etc., which accumulate about a bessemer or open-hearth furnace or casting ladle, and known as *kish*. The graphite is formed during cooling by the crystallization of the excess carbon from the molten iron, and the graphite, which may reach 8-10 per cent, is in the form of light, thin flakes. If the mixture containing the graphite is carefully screened and treated with magnetic separators, the graphite may be concentrated and refined. The supply is probably not great enough to present a commercial possibility at the present time, but may form a worth-while source in the future.

## Flotation Applied to Fuel

THE experiments which have led to the perfection of the Trent process for the treatment of coal illustrate again the success which often attends the application of processes peculiar to one field to the problems in another. Certain types of coal carry their ash in a form sufficiently segregated to make it possible to separate it by ore flotation methods. This removes about eighty per cent of the ash and gives an oil-coal fuel possessing desirable characteristics. If advantageous, the oil could be recovered. One of the best features of the process is the possibility of reducing the coal to a fineness sufficient to pass a 200-mesh sieve by wet grinding methods, thus eliminating one of the principal hazards in the use of powdered coal, namely, the liability to spontaneous explosion of the very fine dry carbon dust.

## Experimental Coal Mines

DR. J. J. RUTLEDGE presented an argument in favor of demonstration coal mines before the American Institute of Mining and Metallurgical Engineers at their February meeting, urging the importance of such mines if the most is to be made of the technical skill that can be employed in solving the problems of underground coal mining. Some of the experiments which could be tried are: Satisfactory methods of stopping the slacking of mine roofs during the summer; determining the best method of mining in a particular field; developing better methods of timbering; a study of proper explosives; mining machines; methods of haulage; ventilation; generation and distribution of power; efficient pumping; greater safety in shot-firing; and a testing of the roof or bottom shale in metallurgical plants or in the manufacture of brick or terra cotta ware.

## Carbon

THE work on special charcoals for gas absorption in gas warfare defense has brought to many a better appreciation of the differences in charcoal and other forms of carbon. The field offers a wonderful opportunity for research of the most profitable kind, when the usefulness of carbon for clarifying and decolorizing is fully considered.

Lately a number of laboratories have undertaken the problem, their work differing in the raw materials as well as in method. Rice hulls, kelp, and lignite are some of the raw materials used. The premium which we pay because we have not been sufficiently interested in developing suitable decolorizing carbons is illustrated by the fact that one foreign company has met with much success in first licensing the use of their carbon at $5,000, then selling the material at $500 per ton, and in addition receiving a royalty of thirty cents for each 100 pounds of material decolorized with this secretly prepared carbon. A number of concerns use the material even under these conditions, and the prize should be enough to attract some of our best physical chemists.

## Motor Spirit

THE *Journal of Commerce* reports a new process for the extraction of commercial alcohol which, though still in the experimental stage, is said to be capable of producing a satisfactory motor spirit. The work has been carried on in England, where alcohol and derivatives have been recovered from coke oven gas by a sulfuric acid contact process. An average yield of 1.6 gallons of alcohol per ton of coal carbonized is reported and it is calculated that if all of the coke oven gas from the coal reduced to coke in England during 1918 had been subjected to this process, more than 23 million gallons of alcohol would have been recovered.

## Non-Coking Coals

EXPERIMENTS conducted at the University of Illinois on low temperature carbonizing of coal have been reported to the American Institute of Mining and Metallurgical Engineers, and while the work has really but begun, the indications are that the so-called non-coking coals of Illinois may be advanced one of these days into the class of coking coals. Working at 750°C., the gas produced was high in calorific value and the tars were of unusual interest.

## Methanol

IT has been pointed out before that in view of the importance of wood alcohol to the chemical industries, the legislation which might be enacted as the result of its use as a beverage became a subject for serious consideration. In the belief that the names wood alcohol and methyl alcohol were partly to blame, a change has now been agreed upon so that hereafter this article of commerce will be known as methanol.

## Aircraft Dope

FOR some time "dopes" made from cellulose acetate have had the preference for coating fabric used in aircraft production. It is more expensive than materials composed of cellulose nitrate since in their manufacture acetic acid and acetic anhydride are required and these raw materials are more expensive than those employed in the nitration of cellulose. However, the acetate is fire resistant or slow burning and that has given it a decided advantage. It has now been found that some five to eight per cent of ammonium magnesium sulfate when added to the nitrate makes it fire resistant, since when ignited a quantity of ammonia gas is given off extinguishing the flame.

## Furfural

FURFURAL is another of those substances upon which comparatively little industrial work has been done because of its scarcity and price, which made it out of the question for manufacturing purposes. Few industries could afford to pay $17 a pound for raw material. In attempting to use a part of our annual crop of corn cobs, it has been found that furfural is one of the materials that can be prepared, either as the principal product or as a by-product, and costs as low as ten cents per pound have been realized. At the Bureau of Chemistry it has been found that furfural may become the starting point for a large number of dyes which may become as important as one of the series now obtained from coal tar products. It may be condensed and, experimentally, a fast brown dye has been made by treatment with sodium sulfide for wool and silk, and with ammonium sulfide for the direct dyeing of cotton. The stimulation of such valuable research is sure to follow from the establishment of our organic chemical industries, but without encouraging legislation this will be impossible and development which often produces values in unexpected places will be stifled.

## Carbon Black

CARBON black is a fluffy, velvety pigment, usually produced by burning natural gas with a smoky flame against a metal surface and the product is entirely different from lamp black, with which it is sometimes confused. Lamp black is gray in comparison with carbon black and in all places where carbon black is used lamp black is practically an unsatisfactory substitute. In normal times we have been in the habit of exporting about 15,000,000 pounds and besides this have used in printers' ink ten to twelve million, rubber goods, twenty million; stove polish, four to five million; and miscellaneous, one million pounds annually.

The Bureau of Mines has undertaken an investigation of probable sources of lamp black and with the gradual lessening of our natural gas supply the question of carbon black may become a rather serious one. The present methods are known to recover but a few per cent of the carbon in the gas, and developmental work on efficient methods of production from natural gas and other possible materials is in order. The thermal decomposition of gas or other hydrocarbons with insufficient supply of air, or explosion with carbon monoxide, carbon dioxide, oxygen or their mixtures has been suggested.

**Some close-up views of the garden slug, with special reference to his major occupation of eating**

## A Queer Visitor in the Garden

**By Hamilton M. Laing**

HIS book name is Ariolimax columbianus, but he is better known as just plain "big slug." He *is* a big slug—almost unbelievably big when first we meet him. He attains a length of seven and a half inches and a thickness greater than that of a man's thumb—a veritable leviathan of his kind. When we meet him stretched out on his way across a woods path or find him clinging to vegetation far from the ground, he is like something seen only in the nightmares of a small boy.

In general appearance this slug is like a huge snail minus his shell. Instead of a shell on his back he carries merely a mantle and his single breathing pore is through the right side of this mantle. His eyes are perhaps his most peculiar feature: he has a double set of "horns" or tentacles, the front pair short, the hind pair much longer and in the tip of this rearward pair are his eyes. He can "pull in his horns" in very truth and the eye comes too—periscope and feeler in one. Also, each tentacle works independently of the other. His color is tawny green and his back usually is more or less mottled with brownish—just the combination to hide his slow-creeping form from prying eyes that might be peering about in the shadows of the moss-green woods.

A most interesting thing about him is his manner of getting over the ground. When extended and on the march his body seems magically to slip forward; we have to look closely to mark his steady progress; the slime trail behind him is best evidence. Though he has no legs he does not wriggle forward like a snake. His under surface really is his "foot" and he is glued to the ground, this flat member sticking tight and secreting the slime that marks his path. He moves forward in sections. His head and foreparts extend momentarily and after them in a series of minute ripples come the more rearward segments. In this way he can climb any obstacle from the spiny bark of the devil's club to the surface of a pane of glass. Timed and measured on a woods path he has been found to make two and one-half inches in two minutes or six feet three inches in an hour. Yet the scientists say that this slow-going chap came to Oregon and California from Asia, by way of Alaska; and that he walked!

The slimy trail glittering in the morning sun upon the cement walk or on the earth in the garden is the unfailing sign that Ariolimax has left the woods and come for a visit. When he is traveling extensively the amount of this mucilage he has to manufacture is considerable. Why he does not become permanently glued down with his own adhesive is one of Nature's mysteries; for when the mixture is taken between the fingers and worked half dry it has the stickiness of commercial glue. Doubtless one reason for the slug's dislike for the sun is that he is in danger of being dried up and cemented down.

Usually one of the interesting things about a creature is its food and it is over the food question that this big slug comes into closest touch with man. He comes out of the woods and into the garden for a purpose. His appetite is tremendous and there is little that he will not devour from a whole row of new lettuce to the top sprays of the tall chrysanthemums. What he eats seems to depend on circumstances; for when his expedition lands him on the lawn he accepts

(*Continued on page 268*)

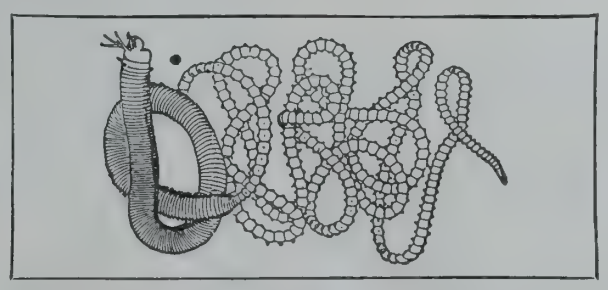
## Ships for Sheep

THANKS to that Western ingenuity which has so frequently overcome extreme obstacles, a three-decked barge has been devised for transporting sheep from winter to summer pasturage on the Chelan National Forest, Washington. The time element in moving 3,000 head of sheep has been reduced from 15 days to 15 or 20 hours.

**Big barge for moving sheep from winter to summer grazing grounds**

The accessibility of Lake Chelan, 3 miles wide and 50 miles long, renders practicable the use of a barge in hauling the livestock. Formerly, the sheep were driven overland from the winter to summer grazing territory, the tedious journey of 15 days through rugged mountainous areas proving disastrous to many of the lambs.

A gasoline boat propels the three-decked equipment,



**The palolo worm of the South Pacific, showing the rear portion that breaks off**

which was specially designed for the purpose. About 1,000 sheep are carried on each trip, the expense being 12 cents for each head. The barge is a connecting link between summer and winter pasturage, the sheep leaving the winter range country in the spring only to return when the leaves again assume a tint of hue in the fall. The lake itself is at an elevation of 1,800 feet above sea level, and is a dividing line between varying areas as to climatic conditions conducive to luxuriant pasturage.—By *S. R. Winters.*

**A moat designed to protect garden plants from slugs**

## Headless Worms—A South Sea Delicacy

EVERY year in October and November enormous swarms of the so-called "palolo" worms suddenly appear on the day before the last quarter of the moon along the coasts of the South Sea Islands. The natives await this event with keen interest, since they highly esteem these worms as a delicate tit-bit whether eaten raw or roasted. It is said, too, that Europeans who have succeeded in "acquiring" a taste for them find them very palatable and appetizing. It has long been noted that these creatures were always headless and this circumstance has now been explained, says a writer in *Kosmos* (Stuttgart), by the fact that the palolo worm is really only half a worm! In other words it is the rear portion of the body of an annular worm, the *Eunice viridis*, which finds its habitat in the crevices of coral reefs. This curious creature has its body divided into two sharply defined portions, as shown in the accompanying illustration. The essential part of the animal is the upper portion of the body, consisting of thick broad "rings," while the lower portion or "tail" is composed of much smaller annular segments. This part of the body, which may reach a length of 50 cm., is devoted to reproductive purposes. At the period of sexual maturity this section of the worm, which is filled with sexual products, breaks away from the main portion of the body and rises to the surface of the water, where it swims about for a time and then gradually separates into its segments, which discharge their contents into the water, thus fulfilling their function. Meanwhile the parent animal peacefully leads its obscure existence in the rifts of the coral reef and proceeds to grow another "tail." This is a typical example of the self-crippling capacity so often seen in the animal kingdom, and shows what an important biological function this peculiar power may serve. In this case, of course, the principal purpose is the extension of the territory in which the worm exists, since the lightness of the rear portion of the body enables it to float far and wide from the place of its origin.—By *M. Tevis.*

## Novel Plant Protection

IN the case of a rock garden, which contained a number of valuable Alpine plants, much trouble was experienced from slugs. Some important specimens were badly damaged by the pests and all ordinary means of keeping the enemies at bay were without avail. A plan which met the difficulty is pictured.

All around the garden a ditch was opened up. This was about 9 inches in depth and 7 inches in width. Strips of sheet zinc 20 inches wide were then secured. These were bent around in a U shape. The ditch was lined with cement and the zinc trough placed in position as shown, with the cracks cemented over so that the whole arrangement was water-tight.

When the garden was completely encircled with the zinc trough water was poured in. In this way the rock garden was completely cut off from the surrounding area. For a few days a thorough search for slugs was maintained among the Alpine plants. When all these had been destroyed there was no further trouble with the pests seeing that none of the creatures was able to cross the water barrier.—By *S. L. Bastin.*

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*

This device brings the emergency brake lever fully 6 inches nearer the driver's hand

## Bringing the Emergency Brake Within Reach

A NEW device introduced by a Los Angeles firm brings the emergency brake handle within reach of the driver without the tiresome groping and stretching for the iron handle.

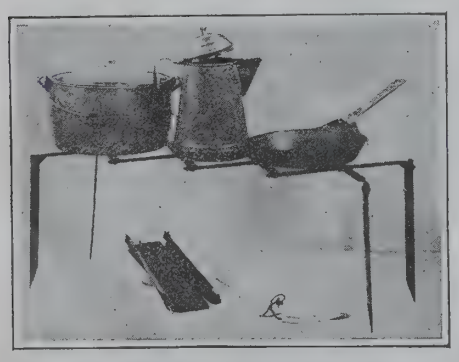
The device trips the ratchet of the emergency brake by means of a release which operates with the same movement of the hand that sends the lever backward or forward. The ball grip is easily grasped and the lever is, in reality, brought six inches nearer the operator's hand by using the device.

## Radio Banking Service

IT is reported that wireless banking is a success aboard the ex-German liner "Imperator." The Cunarder has established the first sea bank with a safe large enough to carry a huge amount of cash. Drafts on shore banks are honored and the money transferred by radio.

## A Camp Grate That Folds

WHEN this camp grate is folded it is only four inches wide and twelve inches long, with a weight of five pounds. When it opens it has a cooking surface of 36 inches, and will support three large cooking utensils.



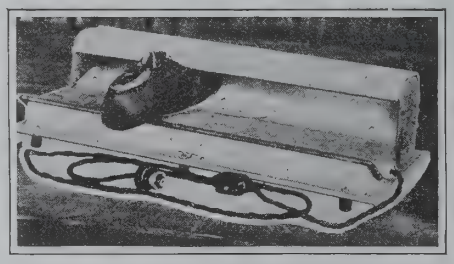
This camp grate can be folded into a small bundle 4 inches wide and 12 inches long

## Reclaiming the Barren Land

IN order to reduce the scarcity of food on the one hand and to increase the land available for settlement on the other, the German Government has suddenly turned its attention to the reclamation of barren lands. The area of barren land yet to be found in Prussia alone is estimated at not less than 3,705,000 acres. Between 1850 and 1918 approximately 1,970,000 acres were brought under cultivation. A further 3,705,000 acres of rich soil is yet to be obtained by drainage.

## A Stove That Softens Shoe Toes

THIS is one of the improved electrical devices used in the shoe business. It will not burn leather, yet it softens the toes and speeds up production. The shoe is placed right side up with toe of last under the shelf. An adjustable rod on top holds back the vamp keeping the box toe flat on the slab. Heat is regulated by a thumb switch. It is not necessary for current to be turned on continuously as when the asbestos slab is hot it will retain heat for some time without current. It requires but a very few minutes to soften the shoe toe so that it can be lasted by hand or on a machine.



The toes of shoes are softened in this small electric stove

## The Tilting Table Saw

AS the term "tilting table saw" implies, the force of gravity is capitalized in chopping wood by pivoting the table to the lower portion of the frame and so constructing that when a cut is finished the downward tug will pull the table from the saw and into position for moving the wood up for the succeeding cutting performance. The design is especially adapted to cutting cordwood or short chunks—frequently phrased as "stovewood length."

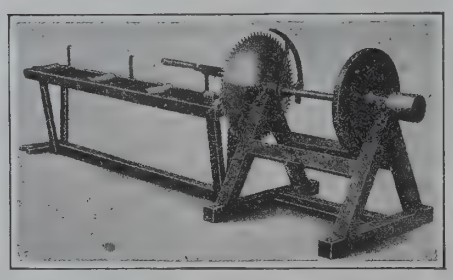
When designed exclusively for cutting cordwood, the table is constructed immediately in front of the saw mandrel, the uncut portion of the wood passing between the flywheel and the saw blade. The severed chunk then can fall directly to the ground, eliminating itself for the succeeding cut. The saw mandrel is less than 4 feet in length; and if the flywheel is stationed on the saw mandrel, poles or other lengthy pieces of wood cannot be placed on the table without coming into contact with the flywheel.

Consequently, tilting-table frames designed for chopping pole wood are of a varying construction. The flywheel is mounted on another shaft, permitting its operation below the table, or the latter is stationed on the side of the saw blade away from the mandrel. Such an arrangement permits of the wood being fed to the saw from the outside.

## A New Wheel Guard for Railroads

A NUMBER of men prominent in railroad circles and other men who preside over safety departments, got together in a northern Ohio town not long since to witness actual tests of the new guard which is attached to the front end of cars and extends to within a few inches of the rails. All tests were made with a dummy, weighing as near as possible the average weight of men employed as brakemen, switchmen and in other railroad capacities. In all tests, at which time the dummy was placed in positions resulting from falls from moving trains, the guard cleared the track of the obstacle, and in only one was it injured. This was in a case in which the dummy sat upon the tracks, and was passed under the train between the wheels, uninjured with the exception of having its overalls torn and scratched.

The guard itself is a forged bar of steel curved to conform to the shape of a car wheel. The upper end is T-shaped which provides means for bolting it to the carbolts of the underframe. The lower end holds a slipper. Normally this balances, but when an object is forced against it, it drops to the track and clears off any obstruction. It will not only be the means of saving lives of railroad men, but will prevent train wrecks caused by obstacles falling across the tracks. A large railroad tie was placed in such a position, and as it came in contact with the guard it was thrown aside and the train of several cars passed in absolute safety.



A tilting saw table which simplifies and speeds up sawing

## Saving the Heat That Goes Up the Chimney

IT is a well-known fact that with the fuels at our present and past disposal we are, as we have been, highly extravagant. So far as the consumer is concerned, to be sure, this extravagance is often involuntary, being attributable to furnace, stove and oven design that makes impossible the full utilization of the heat produced. In particular it is quite usual to have the gases that pass off up the chimney carry with them several hundred degrees of heat, which has not been utilized in any way.

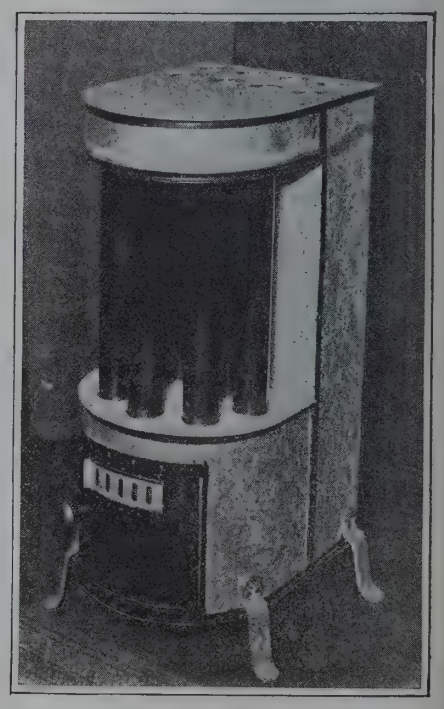
In the effort to use to the full the heating power of the conventional briquettes, a German manufacturer has placed on the market a briquette stove constructed on a new plan. The stove in question takes briquettes of brown coal or turf, and will likewise burn artificial fuel of various sorts, made from coal and coke tailings, etc. It is claimed that three briquettes will heat a room of moderate size. It is in some use as a sort of preliminary warming medium for rooms in which the temperature is later to be maintained by the rather more economical but not nearly so effective tile stove which has for so long been the bane of travelers in Germany.

These simple wheel guards are attached to railroad cars for safety's sake

The trick of this stove is the passing of the gases of combustion through the several heating chambers before they go to the chimney. They are allowed to retain only so much of their heat as is necessary to insure a good draft. Utilization of the heat heretofore carried off by these gases is effected through a quantity of tubes, arranged vertically in the chamber, and affording the necessary absorbing and radiating surface. The tubes are open above and below, and the gases pass freely through them and to the chimney. Effective radiation of the heat is assured by the exposure of the surface of these tubes to the room atmosphere, as indicated in our illustration.

## Canada and Carbide

THE manufacture of calcium carbide at various points throughout the Province of British Columbia is being strongly advocated these days. This material, which is manufactured from limestone and coke by subjection to heat in an electric furnace, is used for the production of acetylene gas, as a substitute for gasoline, and for certain chemical purposes. One ton of calcium carbide is obtained from 3,000 pounds of the mixed material.



German stove with unusually large radiating surface

# *The Farm Electrical—*
## *bigger crops, greater comforts*

WHAT farmer has not dreamed of the day when he would no longer be "the man with the hoe." And to many farmers, the day of realization is already here.

The electric power line is reaching the most remote districts and with it a new science, a new system and a better, more prosperous life for those who produce life's necessities.

Thousands of acres of arid, unproductive land have been reclaimed and made to yield glorious harvests, through irrigation with electric motors and pumps. Tilling, planting, harvesting, threshing, ensilage, cutting and storing of grain may be done quickly with less work and greater profits for all concerned.

"Chores" which get the average farmer up early and keep him up late, may be motorized at little expense. Today, the water is pumped, the cows milked, the butter churned, the milk separated, the tools kept sharp—all by electrically driven appliances.

And the farmer's wife? With electricity as her housemaid, life is worth living. Cleaning, washing, cooking and sewing are done at the touch of a button. When evening comes there is the MAZDA Lamp and comfort, for electricity has done the day's work and will do tomorrow's.

To make the electrical machinery which generates and transmits this force, to study its application in the form of light, heat and power and to make it available for the betterment of all mankind, is the endeavor of the General Electric Company, exemplified in a service which has extended over a quarter of a century.

95-167

GENERAL ELECTRIC COMPANY

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Pertaining to Aeronautics

AIRCRAFT HAVING INHERENT STABILITY.—J. A. FLEMING, 10 W. 65th St., New York, N. Y. The primary object of the invention is to provide an aircraft having a novel arrangement of surfaces and structure, making it inherently safe. Another object is to obtain longitudinal and lateral stability and to prevent sideslipping. Another object is to obtain the maximum of lift, and a low forward center of gravity by disposing of the greatest weight to the forward end of the body of the aircraft.

### Electrical Devices

FLASH LIGHT TESTING APPARATUS.—G. A. LEY, 3912 No. Seeley Ave., Chicago, Ill. The invention relates to flashlight photography and the testing of apparatus for use in connection therewith. An object is to provide a lamp box and lamp for testing the electric circuit connection which is to be used in blowing a fuse and igniting the flash powder; the device may be used with a battery in which case a battery box is provided with the lamp box or with the ordinary city current.

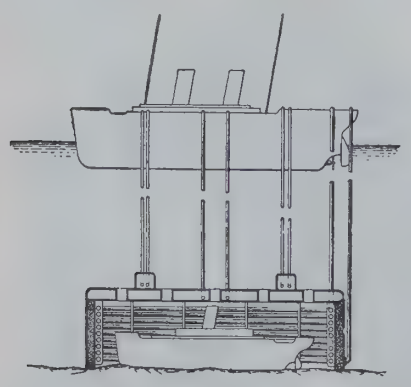
### Of Interest to Farmers

WAGON LOADER.—G. HAISS, 141st St. and Rider Ave., Bronx, N. Y. This invention has for an object to provide a device which is automatic in its operation. A further object is to provide a device in which the operation is continuous so long as there is any material to be operated upon. A further object is to provide a machine particularly adapted to operate upon piled material, and means for feeding the piled material laterally.

APPARATUS FOR HANDLING RACKS.—F. J. LOVERING, Octavia, Neb. This invention has for its object to provide a device especially adapted for placing and removing hay racks and wagon bodies from the running gears of wagons, wherein a wheel supported standard is provided, having means for lifting the rack or body one end at a time and placing it on the running gear, the wheels and the rack having means for preventing skidding movement during the lifting of the load.

### Of General Interest

APPARATUS FOR RAISING SHIPS.—W. F. GRUMME, 203 W. 103rd St., New York, N. Y. A hollow pontoon is provided by this invention which is adapted to be towed to and lowered over a sunken vessel. The pontoon is



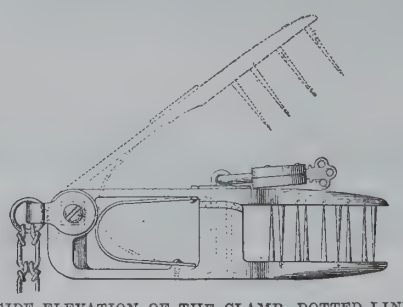
SHIP SALVAGING APPARATUS

provided with refrigerating means whereby the water enclosed within it may be frozen into a solid block of ice. When this is done the buoyancy of the ice brings the block, with the ship it contains, to the surface.

ROSETTE FOR BRIDLES AND OTHER PARTS OF HARNESS.—H. L. DAUGHERTY, Box 607, Carson City, Nevada. The object of the invention is to simplify and cheapen the construction of harness parts at the same time making them durable and attractive. The rosette comprises a hollow body having an inner flat wall provided with a transverse slot, and with a keeper adjacent the slot, a latch bar having a slidable connection with the keeper and having an angular portion adapted to enter the slot to engage the inner face of the flat wall and hold the latch bar in place.

SIGHT FOR FIREARMS.—J. E. KRAFT, Groveland, Cal. One of the principal objects of the invention is to provide a sight representing such a color to the marksman that it will contrast with the object aimed at. A further object is to provide a sight whose visual surface will be disposed at such an angle to the gun barrel that it will be always properly illuminated, irrespective of the angle at which the light falls on the sight.

ROBE SECURING DEVICE.—R. REID, 15 Jackson St., Sanford, Me. The invention pertains more particularly to robe clamps, and to devices of this character especially adapted



A SIDE ELEVATION OF THE CLAMP, DOTTED LINES SHOWING OPEN POSITION

for use in connection with vehicles. The primary object is to provide means by which a lap robe may be left in an automobile without danger of its being stolen therefrom.

CLASP.—L. B. HOCHSTEIN, 22 North St., Endicott, N. Y. The primary object is to provide a casp of the pivoted type especially adapted for retaining the open ends of a box or pasteboard carton in close relation. A further object is to provide a device which will be flat when in its operative position, and which may be entirely removed when in its inoperative position.

TOWEL CABINET.—E. J. SHAUGHNESSY, c/o F. O. Hendrick, 137 Greenwood Ave., E. Orange, N. J. An object of the invention is to provide a support for a continuous towel strip which facilitates the use of the strip. A further object is to provide a towel cabinet which will be economical in that the portions of the towel which are in use are maintained in a smooth condition, and the dirty or soiled portions are maintained out of contact with the clean, fresh portions thereof.

SETTLING TANK.—S. F. KELLER, Thebodaux, La. The invention has for its object to provide a tank of the continuous operating type for the clarification or separation of sugar cane juice or the like, after the juice has been treated with sulphur dioxide and neutralized with calcium hydrate, wherein the juice follows the natural trend of liquid that has been heated.

AMMONIA DISSOLVING COMPOSITION FOR USE IN REFRIGERATION APPARATUS.—C. DELAYGUE, Paris, France. An object of this invention is to provide a refrigerating composition which will dissolve large quantities of ammonia under high pressure with a resulting small volume. Another object is to provide a refrigerating composition which may be freed of ammonia by heating without giving off other volatile substances which would interfere with the refrigeration process. The composition consists of ammonium nitrate 3 grams, trimethylamin 2 grams, liquid ammonia 554 cubic centimeters, and sufficient water to make one liter.

### Hardware and Tools

LOCK.—L. E. CANTRELL, address L. M. Gibson, Maxwell House, Nashville, Tenn. The invention relates particularly to "pay-as-you-enter" locks which allow a person to enter a door on depositing the required coin. A money register is embodied within the lock to count the number of coins deposited and also the number of entrances through the door.

TOOL FOR REPLACING SUCKER RODS.—E. B. HATCH, Box 175, Turley, Okla. The invention relates to a tool for use in replacing sucker rods in oil wells. The object is to provide a tool by the use of which the dangerous operation of lifting the rods off of the elevator will be done away with, and which will make it impossible for rods to get away from the brakeman by proving a check for the rods in case the line should break, which will prevent the rods from falling farther than the tubing nipple.

### Heating and Lighting

COMBUSTION DEVICE.—S. YOUNG, Yquitos, Peru. The object of this invention is to provide mechanism of the character specified for permitting the utilization of fuel in the form of shavings, paper, straw, slack and the like, and for insuring the complete combustion of the same, and for conserving all the heat generated during combustion.

### Machines and Mechanical Devices

CRIMPING MACHINE.—E. T. REUTER and W. A. SKINNER, 366 Pearl St., Manchester, N. H. An object of ths invention is to provide mounting and operating mechanism for a pair of form plates instead of one which doubles the capacity of the machine over the Legge machine and which facilitates the employment of guards to protect the operator. With this device one of the plates is always descending so that double production is possible.

### Medical Devices

TRUSS.—G. H. EDDLEMAN, c/o J. Edington, Baltimore Bldg., Memphis, Tenn. The object of this invention is to provide an arrangement whereby the truss when once adjusted and placed in proper position may be permanently worn and all necessity for its removal, for instance in the bath, may be eliminated. A further object is to provide for various adjustments by which the pad may be properly and comfortably seated and thereafter locked in the desired position, permitting of free body movement.

### Musical Devices

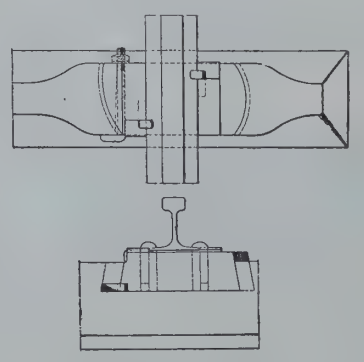
PHONOGRAPH NEEDLE.—J. HEINO, 1178 Washington Ave., New York, N. Y. This invention pertains to a phonograph needle which may be used any number of times, but in which the actual playing point is not of sufficient hardness to damage the record. A further object is the provision of a needle which shall incorporate means for holding the playing point so firmly that it is impossible that any slipping of the same might occur, but which nevertheless is capable of being instantly loosened and removed without the help of any mechanical skill.

### Prime Movers and Their Accessories

ROTARY ENGINE.—S. E. KOCHENDARFER, 58 N. Main St., Washington, Pa. This is an improvement on a prior application (Serial No. 164,436) which disclosed a rotary engine having L-shaped pistons. When the rotor was revolving fast there was a tendency for the piston to jump past the intake port and in certain positions to swing inwardly permitting escape of steam. These tendencies are overcome by an improved construction disclosed in the present patent.

### Railways and Their Accessories

CROSSTIE.—J. R. DOOLEY, 7 So. Springhill Ave., Mobile, Ala. The prime object of the invention is to provide a cross tie whereby rails may be supported and mounted thereon, and although the rail mounting may become defective on account of wear it will not be



A PLAN VIEW AND SIDE ELEVATION OF THE INVENTION

necessary to replace a cross tie, the construction being such as to enable the removable rail supporting section or block to be used, which may be removed from the cross tie and replaced in a practical manner. Another patent has been granted to the same inventor, the prime objects of which are to provide means for securing railway rails to the ties and for securing the meeting ends of the tie sections together.

LATERAL TAKE-UP DEVICE FOR LOCOMOTIVE AXLES.—H. B. FURSTONBURG, 1801 Park Ave., Shreveport, La. The present invention is an improvement on the inventor's previous patent (No. 1,202,701) which showed inner and outer take-up sections adjacent to each of the driving boxes, the inner sections being keyed to the axle and the two sections having abutting flanges. In the present invention collars are substituted for the inner sections and the flanges as well.

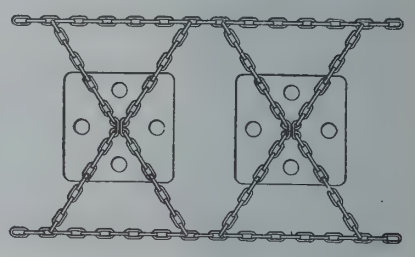
### Pertaining to Recreation

TOY AIRPLANE.—P. O. ROTH, 28 Pullis Ave., Middle Village, N. Y. A toy airplane of simple and comparatively cheap construction is provided by this invention. The toy is intended to fly a short distance through the air when thrown or projected by pressure from the rear. It is of strong construction and will maintain a substantially straight course on an even keel.

RACE GAME APPARATUS.—R. M. BRENNER, P. O. Box 151, Palisade, N. J. This is an improvement on the constructions described in patents No. 1,011,563 and No. 1,203,474, previously granted to Mr. Brenner. In the present invention each actuating device controlled by a player is rendered inoperative as soon as the racing figure reaches the goal. The construction insures winning of the race by the operator who exercises the most skill rather than speed.

### Pertaining to Vehicles

ANTI-SKID CHAIN.—E. BENJESTORF, Fenwood, Saskatchewan, Can. In connection with tire chains for the wheels of motor vehicles the inventor provides relatively flat plates



ANTI-SKID TREAD PLATE FOR TIRES

with lugs or projections which serve to prevent skidding of the vehicle. Owing to the fact that short lengths of chain pass between the lugs the possibility of clogging of the lugs with mud is removed.

ATTACHMENT FOR MOTOR VEHICLES.—D. L. STROUD, R.F.D. No. 2, Box 13, Mabel, Minn. The object of the invention is to provide an attachment adapted to support the rear wheels of a motor vehicle out of contact with the ground, to permit them to rotate freely to drive machinery of any character, and wherein means is provided on the attachment for permitting the rear end of the vehicle to be quickly and easily lifted on to the attachment to support the wheels for running freely.

HYDRAULIC JACK.—A. PAOLI, Hancock, Mich. The invention has for its object to provide a jack, small and compact of form, and especially adapted for use with motor vehicles, wherein a cylinder is provided having a base and a hollow piston movable in the cylinder and having movable therein another piston to which the saddle is connected, together with means for moving the hollow piston downward, to provide for a large amount of lift with small amount of controlling movement and without the use of valves or the like.

### Designs

DESIGN FOR A LAPEL RIBBON.—A. TILT, 51 E. 79th St., New York, N. Y.

DESIGN FOR A PIN, BADGE, FLAG OR SIMILAR ARTICLE.—C. A. HOWARD, 9 Maiden Lane, New York, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

IN the bearings sponsored by SKF its type of anti-friction bearings have been developed to their highest perfection. And SKF further provides an engineering service not only to assure to itself proper application and use of SKF marked products but to help the buyer to fully capitalize the mechanical value built into each device. This service is freely offered and is being continually broadened and advanced by laboratory research that is international in scope. You are assured a similar service behind every product bearing the mark—

*Dual Protectors*
*Of the American Home*

WHAT home would be without the beneficent insurance policy which restores and repairs after loss and damage? Without insurance those catastrophes, beyond the power of individuals to prevent, would be complete. And we companion this insurance with the protection of a COLT to thwart harmful and evil influences which, unless prevented, lead to catastrophe.

Thus—the stealthy shadow of the auto thief, seen from your bedroom window at your garage door, vanishes into the night when you challenge him with a COLT.

The sneaking figure of the fire-bug who, with vengeance in his heart for a fancied wrong, means to make a ruin of your home or factory when surprised, surrenders when confronted with a COLT.

The night prowler caught upon your veranda has no other thought but flight, instead of the savage rush he premeditated, when he comes face to face with a COLT.

Instead of battling the futile resistance of empty hands, the bold hold-up man who has stopped your car on the lonely highway becomes a shrinking coward when he finds you argue with a COLT!

And so we have the dual protectors of American homes, the insurance policy which provides a recompense for those losses which could not be helped, and a COLT Automatic Pistol or COLT Revolver which reduces to a minimum the unpreventable danger.

When you buy a COLT remember that you are getting "The Best that Money can Buy." Nothing else should satisfy.

Drop in and talk it over with your dealer.

## Splitting Hairs With Close-Limit Tools

(*Continued from page 243*)

it is considered that 20 degrees Fahrenheit difference in temperature will change the length of an inch block by more than twice the margin to which the close grinding is held. The heat of the hands and the heat of the machines make so much difference that the work is checked on the indicator gages between successive grinding operations.

The final few molecules are caressed off the blocks by the die-making group, who get and assemble the parts. By a series of gentle rubbings against flat cast-iron blocks, they finally bring the various sections to so nearly the same size that it is necessary to split an inch into millionths to find out which is which. The slots in the blocks that hold the die sections, the punch sections and the shedder sections must be made to almost exact dimensions, and must have their sides absolutely parallel with each other, and absolutely perpendicular to the surface of the blocks.

Then there is the little question of "locating holes" and "locating pins," which must be accurate to about half a medium heavy shadow, and a lot of other close work that requires more patience than answering questions in an orphan asylum.

It is possible to work to even closer dimensions than the hundred-thousandth of an inch limit on the most particular class of tools, but it very rarely is done. For instance, there are two firms, one in this country, and one in Sweden, that make standard blocks of various lengths which they guarantee to be of exact size to within a few millionths of an inch. Either firm will, upon special order, furnish blocks within one millionth of an inch variation from true size. The check measurements on the blocks produced in this country are made by optical methods, using the wave length of light as the final measure, as has already been told in these columns.

## The Greatest of Floating Cranes

(*Continued from page 247*)

tional facts now before us it will readily be understood perhaps that the operation of transferring a big 250-ton gun mounting would run through substantially the following series of movements. The crane stands up about as erect as it can and swings around on its roller bearings until it has the gun mounting before it. The load is secured and lifted by operating the tackle connected with the rear hoisting blocks. There are two independent blocks, each capable of a lift of 125 tons. But there is a special block with which they may be interconnected, the whole combination being able to deal as a unit with the 250-ton load. The crane now rotates once more on its roller bearing until it faces the location where the mounting is to be deposited. It then extends its reach by flattening the angle of the jib. When the load is above its destination, the steel tackle is again operated and the mounting deposited.

The arm or "neck" with which the crane reaches outward and withdraws inward is the longer part of a single unit. The shorter part is another arm set at an angle of perhaps 135° with the longer part, the whole forming a bent boom. The whole is a rigid unit. It is pivoted at the bottom of the short part. It has but a single movement up and down in a vertical plane. The lifting and lowering of the load is or may be done ordinarily with one of the block-and-tackle devices without any movement of the bent boom. The boom itself is elevated and depressed with or without the load, the point at which it is stepped being the center of its radial movement in its vertical plane. This depression and elevation of the boom is accomplished by one of the most interesting features of the whole affair. Back of the boom is a triangular rocking beam. One vertex is hinged to a central framework at a level about half-way between the foot of the boom and its elbow. Another vertex is linked to the elbow, while the third—farther to the rear of the boom—is linked to the vertical cross-head of the elevating device. The cross-head shifts up and down in a vertical plane, these movements being accompanied by a lowering and elevating of the jib. Double plate girders provide for the guidance of the cross-head. The shifting of the cross-head between its guides is accomplished by two remarkable screws. These are each 60 feet in length and 13½ inches in diameter. By means of powerful machinery the great screws are simultaneously turned and the boom with whatever weight may be upon it raised or lowered.

*Crane Lighter No. 4* is so weighted by the disposition of its machinery, a certain amount of dead weight ballast, etc., that when there is no load on the crane and its boom has been elevated to the limit and has its minimum reach in an athwartships direction, the vessel heels over 4 degrees and has its deck depressed on the side back of the elbow. When the boom is depressed to the 100-foot radius for the inner blocks and a load of 250 tons is on the hook, the vessel heels the same amount but naturally in the opposite direction. No shifting ballast is employed. The crane has actually been tested with a load of 312 tons.

Hydraulic brakes are employed with some precision in controlling the movements when the great load is on. Steam brakes are also used.

The two floating cranes at Panama—the *Hercules* and the *Ajax*—are duplicates of each other. The pontoon measures, roughly, 150 feet in length and 89 in width. When the jib is withdrawn to its innermost position, its tip is about 206 feet above the deck. There is under the operator's cab a counterweight of 150 tons. A second counterweight three times as heavy is in the after part of the pontoon and a third on the cross-head. All movements are effected through electrical means.

## Malaria Control

MALARIAL control through the application of anti-mosquito agencies re-emphasizes the dictum that an ounce of effort at their breeding places is more effectual than gallons of immunizing fluids after the pesky insect has once obtained a lease on life. Recognizing the necessity of making warfare on polluted streams and other breeding sources of the mosquito, the U. S. Public Health Service has conducted a series of intensive experiments in an effort of controlling production of the germ-laden pest.

Among the unusual control methods adopted in the prevention of the hatching of mosquito larvæ is the spraying of streams with kerosene or a heavy black oil, classified by dealers as a grade immediately below fuel oil. The application is made with knapsack pump sprayers or by means of automatic drip cans. Of course, the expensiveness of the oil is a factor to reckon with, but one small Southern lumbering town made effective its control operations at an aggregate cost of $2,506.40, or a per capita cost of $1.23½. Moreover, the visits of the physicians for the purpose of treating malaria were reduced 70.39 per cent compared with the previous year. The permanency of control methods would undoubtedly curtail the operating expenses in making warfare on the mosquito.

The novel departure of applying the oil by means of a drip can be proved practical by the utilization of small platforms, stationed over the streams, from which cans were suspended. These stands were built of scrub-oak saplings or odds and ends of timber assembled from the lumber mills. Spaced 200 yards apart, the drip cups were so designed as to deliver drops of oil from an elevation

(*Continued on page 262*)

# Where Lincoln Cars are Leland-Built

*The Lelands are noted for advanced methods in making fine machine tools*

*One of the departments where parts are ground to Leland standards of precision*

*Connecting rods are machined all over to remove superfluous weight*

In one of America's most modern factories, here Lincoln Cars are Leland-built.

Originally planned for the production of that marvelous mechanism — the Liberty Aircraft Motor — here produced in largest volume in the shortest time, that wonder work-shop turns to peace-time occupation.

Here now is found an almost limitless array of new equipment, representing added millions of investment and more suitably adapted to the new pursuit.

Here is machinery of the most modern kinds, seemingly more than human in its ingenuity; and literally thousands upon thousands of the most scientific and accurate tools and devices which genius has yet conceived.

Here the guiding hands rank with the world's most adept in their respective callings—men who have devoted their arts, their talents, and their skill to designing, developing, refining and building cars and motors of the finer class.

Here pervades the spirit of co-operation, and of harmony, and of fellowship—a spirit which has its source in the administrative offices.

Here is found ideal environment, that which appeals to men's better selves.

Here, too, are means for healthful recreation.

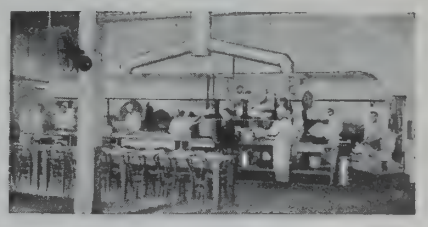
Here men are encouraged to develop the best that is within them; and here honest effort does not go unrewarded.

Here is seen the atmosphere of inspiration; and here is seen incentive to achievement.

Here men of the serious-minded type seek affiliation, not alone for the creature-comforts, but for the skillful training they acquire, and for the prestige which that training wields in the world mechanical.

Here men, and methods, and machinery; here inspiration, environment, and knowing-how, work hand in hand for a common purpose—the production of the highest type of motor car that man has yet evolved.

Here it is that Lincoln Cars are Leland-built.



*Where wholesome food is well cooked and served to employes at cost*

*One of our two main dining rooms designed and built for Lincoln employes*

*A room which invites rest and recreation is provided for women employes*

MATERIAL TRUCKING MEN WANTED AND MATERIALS

## The New Truck With The "WORM-LIFT"

*Lifts From Any Angle And Lifts Higher*

THE National-Chapman *Universal* Lift-Truck has three outstanding merit features. First: A single down thrust of the handle elevates it—no jack or pump motion. Second: It lifts from any angle—may be elevated from a right angle position in narrow aisles. Third: It lifts higher without extra exertion and raises a loaded platform 2⅜ inches off the floor—an obvious advantage on rough floors or in going over floor sills. Wouldn't you like to know more about this truck?

### Malaria Control

(*Continued from page 260*)

of 4 feet to swiftly moving portions of the creek or stream. As the can absorbed the warmth of the day, it was so regulated as to permit of the delivery of 15 drops of oil a minute.

By the drip-can outlet, 1,035 gallons of oil were distributed on old ditches, 70 gallons applied to new ditches, and 258 gallons used in exterminating the mosquito larvæ along street ditches. The 50 drip cans used represented an expenditure of $39, while the cost of constructing the drip-can stands was calculated to be $9. There were two knap-sack sprayers purchased at an outlay of $14.79, and labor and spraying in the operation of control methods were estimated to be $238.69.

### Water Pipes of Wood

(*Continued from page 250*)

coating. Such a coating may be a paint or it may be a disinfectant. It is said that coatings are useful with fir and pine. With redwood the case is not so clear. A mixture of tar and asphaltum is considered excellent for the pine and fir; but redwood has done so well without the protection of a coating that the matter remains in doubt as to this material.

Wood stave pipe is held together by steel bands or hoops placed at frequent intervals. There are two problems here. One concerns itself with the strength of band required to resist the bursting pressure of the contained water. This will naturally vary with the head and with the size of the intervals between bands. The second problem centers on the tendency of the tightened band to sink into the wood. The size of the band, the spacing interval and the bursting pressure—all play their part here. For almost any given pipe line there will be two or three sizes of band permissible, but the spacing for the different sizes will naturally vary also. A representative band is a round rod with a button at one end and, say, 5 inches of thread at the other. A fitting, called a *shoe*, is employed to cinch the ends of a band together. These vary somewhat in design. It is considered important that the shoe should be stronger in the body than the band itself, as thus it is possible to develop the full strength of the rod. A case has occurred, it seems, where the shoe was weaker than the band, and in consequence somewhere about 390 tons of steel were wasted.

The staves make butt joints with the stave ahead and the one to the rear. Naturally, these butt joints are distributed so as not to have an undue number at any one point of cross-section. In order to prevent leakage at these joints, the following precaution is taken. A steel or iron strip, perhaps ⅛ inch thick, called a *tongue*, is arranged to lie half in one stave end and half in the other. Slots are provided to receive the tongue. The width of the tongue will be, say, 1½ inches. Its length is a little greater than the width of the staves at the locations of the slots. This extra length permits insertion of the tongue ends in the side edges of the adjacent staves. They are coated over with an asphalt base paint.

It is said that, in the case of redwood pipe, the life of the bands determines the life of the pipe. It is accordingly important to prolong the life of these hoops and their shoes, and therefore to use the proper coating at the outset. A paint with an asphaltum base is considered a proper one. Now and then a band will have to be replaced; but generally speaking its life is understood to be greater than that of steel pipe. A reason for this has been given. The band, being round, exposes an inconsiderable surface to the weather. Red lead is considered a very good coating material, indeed. Galvanizing is a method of protection that is costly; but it appears to be the only thing employed in the Hawaiian Islands in connection with redwood.

Instead of the continuous wood stave

# The Right Valves for any Pump

Wherever a pump is in use, its satisfactory working depends largely upon the adaptability of the rubber valves employed. Maximum pumping efficiency is to be had only by the use of the right valves for the particular service.

For every pump pressure and capacity, and for every kind of liquid to be handled, there is a style of United States Rubber pump valves exactly suited to the work to be done.

Consult us in regard to your requirements. Our recommendations will be based on the type and style of valve seats used in your pumps, the nature of the material pumped, and the pressure or lift under which the pumps work.

Let us select valves of the right density for your work.

## Water Pipes of Wood

(*Continued from page 262*)

pipe, the whole of whose erection is carried out in the field, one may substitute short lengths of machine-made wood stave pipe. That is, machine-banded or wire-wound pipe may be employed. Such piping may be obtained in diameters ranging up to 24 inches, inside diameter. The lengths run from 8 to 24 feet, and are provided with the collars and couplings necessary to their secure junction in the field. Such pipe is understood to be made for heads running up to 400 feet. The band, or wire, is secured to the pipe by means of pressed-steel clips or staples or both. The sections, once banded, are dipped in melted asphalt and then rolled in sawdust. The asphalt affords protection, the sawdust makes it possible to handle the pipe.

Some of the more important installations of continuous wood stave pipe are the following: At Atlantic City, N. J., a 48-inch line, 5 miles long has been laid across the salt marshes where metal pipe lines have failed. A big piece of wood piping is the line laid for the Erie Construction Co. (a subsidiary of the Ontario Power Co. of Niagara Falls). The whole line is about 1½ miles long. The shorter half consists of 144-inch pipe and the longer half of 132-inch. Pretty big tubing. The maximum head in contemplation was 150 feet. But there is a mile of continuous wood stave pipe which forms part of a big hydroelectric development on the White Salmon River and which has the magnificent diameter of 162 inches. Some pipe! It is carried on wooden cradles 4½ feet apart, center to center. The weight of the contained water is nearly 900 pounds per linear foot of pipe.

## Checking Up the Gas Meter

(*Continued from page 252*)

the building. On large yellow oblong sheets of paper the meter's "pedigree" is entered—the size, the manufacturer, the premises it came from with the date, the number of years it was in service, the number of previous tests, and the date of each test. Beside the spaces for these entries there is a column in which is printed a series of indices similar to the clock faces of a meter, and hands are drawn on the diagrams to correspond to these on the meter under observation.

In the initial testing operation the meter, attached to the prover, is under conditions exactly the same as when in the home. In this first operation the "U" shaped water gage shows whether any gas is escaping from the meter box. Care must be exercised in attaching the hose. Sometimes three minutes are necessary to adjust it to the satisfaction of the tester.

After this preliminary test the meters are opened to see how much repairing is needed. Their condition determines whether they fall into the classification of light, medium, or full repairs. On the tenth floor a force of men puts in the parts which the previous inspection showed were needed. Upon the completion of repairs and a test of the meter for soundness, a high pressure test is made.

Sometimes a leak is not detected by the "U" gage. When this happens the meter case is filled with water. No matter how small the hole, it is soon discovered. After soldering, another test is made for soundness. Ordinary meters have 50,000 cubic feet of air passed through them to detect any defects, like a loose cog or a buckle at any point. In the operation several meters are linked up together, with a connection to a master meter. After this test there is a final one made with the provers before the meters are sent to what is called in the building the State Department—a space on the ninth floor, on the east side of the premises, where inspectors of the Public Service Commission are at work.

## Checking Up the Gas Meter

(*Continued from page 264*)

Here there are twelve proving machines identical in design with the ones used by the company. The inspectors, after verifying the company's tests, apply the seal of the commission at the top of each meter, near the upper edge of the index. So strict are the regulations as to the use of the seal that inspectors are under instructions to carry their sealing irons home with them at the end of the day's work.

On this floor the meters are painted and placed in bays, according to the ownership of the various gas companies throughout the city. On this same floor the prepayment or slot meters are tested.

An important part of the testing operations is the examination of the diaphragms. These are made of Australian sheep leather—found by experience to be the best material for this purpose—and are attached to the metal disks in the measuring chambers. Generally speaking, the disks and diaphragms constitute a kind of double bellows. The quantity of gas used is measured by the number of times they fill and empty—consequently they must not leak in the slightest degree.

Quality of leather and the exercise of all possible care in the manufacture of the diaphragms cannot prevent mishaps to them now and then. In severe weather a meter will sometimes freeze, which destroys the leather. It turns white and gets hard. All diaphragms are examined by an expert with a view to learning the extent of the repairs that might be necessary. In the majority of cases the leather only needs softening. This is accomplished by giving it a bath in Pennsylvania mineral oil heated to a temperature of 110 degrees Fahrenheit.

All new meters are tested for accuracy on the ninth floor. Great care is exercised in the adjustment of the tangent in the valve chamber. The tangent bears the same relation to the testing mechanism as a pendulum to a clock. Hence it must be adjusted to a nicety, if the meter is to meet the requirements set by the Public Service Commission, which, it may be added, guarantees the reliability of all meters upon which is has placed its seal after a test for accuracy.

## America's Bid for the Gordon Bennett Cup

(*Continued from page 253*)

thus lessening wind resistance, they have added 25 miles an hour to 125 miles an hour speed of the monoplane, and from 30 to 35 miles an hour while it is racing at 175 miles an hour or more with flattened wings.

The body of this very remarkable plane is of monocoque construction. In other words, it is made of thin strips of wood bound tightly with fabric strips laid in glue, the strips criss-crossing the under layer each time that a layer of wood is applied. The pilot sits inside the machine completely enclosed by the doors which open on either side just back of the point where the wings cross the top of the body as though laid over it.

The machine is powered with a special Hall-Scott racing engine of the Liberty Six 250-horse-power type, made by the Hall-Scott Motor Car Company of Berkeley, Cal. Although the Dayton-Wright monoplane will probably be the lightest powered entry in the Gordon Bennett race, its designers hope that the relative power and speed achieved will enable it to outfly heavier competitors. The efficiency of the motor is to be further increased by using a special synthentic fuel developed in the Dayton-Wright laboratories.

This unique monoplane will be flown in the races by Howard M. Rinehart, who with Milton C. Baumann, designed it. The plane is known as the "R-B," derived from Rinehart-Baumann.

# As a matter of fact

## Your first R-E-A-L cigarette pleasure will come with Camels

YOU'LL swing into the Camel procession as easily and as delightedly as any of the thousands of smokers who have found these cigarettes an absolute revelation in quality, in refreshing flavor, in mellow mildness and in body! Camels win your favor right from the beginning!

Camels are unlike any cigarette you ever puffed. They are a creation—an expert blend of choice Turkish and choice Domestic tobaccos. As sure as you are a foot high you will prefer Camels blend to either kind of tobacco smoked straight! They are so delightful, so unusual in every way you consider a cigarette!

You get chummy with Camels! They fit in with your cigarette desires just one hundred per cent! Your most exacting cigarette wish will be answered every time you light up a Camel. The satisfaction they impart to smokers is simply joyous.

And, Camels will not tire your taste! Smoke them liberally—always with keen relish! And, Camels leave no unpleasant cigaretty aftertaste nor unpleasant cigaretty odor.

You'll prove out our enthusiasm when you compare Camels with any cigarette in the world at any price!

*Camels are sold everywhere in scientifically sealed packages of 20 cigarettes for 20 cents; or ten packages (200 cigarettes) in a glassine-paper-covered carton. We strongly recommend this carton for the home or office supply or when you travel.*

**AVIATION ENGINES**

**Their Design, Construction, Operation and Repair**

***By* Major Victor W. Pagé, U. S. A.**
**Formerly of the Aviation Section**

THIS treatise, written by a recognized authority on all of the practical aspects of internal combustion engine construction, maintenance and repair, fills the need as no other book does. The matter is logically arranged; all descriptive matter is simply expressed and copiously illustrated, so that anyone can understand airplane engine operation and repair even if without previous mechanical training. This work is invaluable for anyone desiring to become an aviator or aviation mechanician.

The latest rotary types, such as the Gnome Monosoupape and LeRhone, are fully explained, as well as the recently developed Vee and radial types.

**Invaluable to the student, mechanic and soldier wishing to enter the aviation service.**

**Not a technical book, but a practical, easily understood work of reference for all interested in aeronautical science.**

***600 octavo pages. 253 specially made engravings.***

## A Queer Visitor in the Garden

(*Continued from page 255*)

the dandelions; when he reaches the vegetable garden even the rhubarb leaves disappear; and when he lands among the flowers he is equally impartial.

Yet though he is a gormand he is not nearly so destructive as the legions of his tiny brothers, the garden slugs. Ariolimax is big and easily found, easily kept away. Lime or salt is fatal to him. When he encounters either he perishes miserably, the salt especially making a dreadful mess of him: he disintegrates. A sprinkling of dry lime around a flower or vegetable bed usually will protect it except in wet weather. Even dry sand makes a fairly effective barrier, difficult for the invader to cross.

Though not much of the life history of this creature is shown in the garden, something additional is disclosed in the woods. The young are met early in the spring and doubtless the eggs are laid by the adult among the leaves and protective debris of the forest floor. When first hatched the young are like the parent but very small; but they grow rapidly and by the end of May they are about an inch in length. They are colored like the adults but are shorter and thicker in proportion to their length. Their mission in life seems to be merely to eat and grow, and they do both tremendously, arriving shortly at the size of their leviathan parent; and when the rains of autumn trickle through the firs they are ready for a six-foot-an-hour pilgrimage into the garden.

## NEW BOOKS, ETC.

BATTLEFIELDS OF THE MARNE. 1914. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 292 pp.; illustrated; maps and plans.

Combining a history and a tourists' guide, this handbook transforms a tour into a pilgrimage, and makes the very ruins tell their absorbing stories. The fine finish of paper used brings out well the strikingly artistic effect of the hundreds of illustrations. Following practical information that will greatly further the convenience and comfort of the traveler, a tour is outlined for the Ourcq, the marshes of Saint-Gond, and the pass of Revigny. The plans and maps are skilfully drawn and colored.

THE STANDARD ELECTRICAL DICTIONARY. By T. O'Conor Sloane, A.M., E.M., Ph.D. Addition by A. E. Watson. New York: The Norman W. Henley Publishing Company, 1920. 8vo.; 767 pp.; illustrated.

In its 1920 edition, this well-known reference work carries a substantial supplement containing the very latest developments of electrical science. There are 6,000 terms briefly defined; but the definition is immediately followed by a popularly-worded explanation that may run to several hundred words. These little articles are further amplified by hundreds of cuts and diagrams, the whole constituting an encyclopedic exposition of modern theory, experimentation and engineering.

YPRES AND THE BATTLES OF YPRES. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 139 pp.; illustrated; maps and plans.

Ypres, dominated by low hills, was the theater for some hot work during the war. Succeeding situations are here diagrammatically outlined for us. We find a clear account of the first and second battles, the allied offensive of 1917 in its six phases, and the German attacks of 1918. The material, richly illustrated, is so arranged as to make easy a two-day visit to the town and the salient, and covers all features of interest.

VERDUN AND THE BATTLES FOR ITS POSSESSION. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 112 pp.; illustrated; maps and plans.

Verdun took some of the mightiest hammerstrokes of the German army. The battles for its possession may be understandingly followed by means of the plans of the great offensives given in this guide. Our own soldiers helped to clear Verdun, and a noteworthy picture is the panoramic view of the battlefield as seen from a German observation post. There is a good plan of the city, many scenes from its streets, and folding maps that show fine detail.

RHEIMS AND THE BATTLES FOR ITS POSSESSION. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 176 pp.; illustrated; maps and plans.

The bombardment of Rheims and the wanton wrecking of its imposing cathedral form one of the most unforgetable chapters of the war. After seeing the plans and pictures of this excellent guide, we seem to have been actually over the ground. Both the student of the war and the tourist will find this a work well worth possessing.

LILLE BEFORE AND DURING THE WAR. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 64 pp.; illustrated; maps and plans.

Lille, another old historic town, has a page devoted to its history. How it fell in 1914 and how it was delivered after a four years' occupation is told in maps and text. The town is covered in four itineraries with very exact directions to the tourist, aided by plans and embellished by pictures of buildings, monuments, and works of art.

SOISSONS BEFORE AND DURING THE WAR. Milltown, N. J.: Michelin Tire Co., 1920. 8vo.; 64 pp.; illustrated; maps and plans.

This guide follows the same admirable arrangement of others in the series, giving first the chief historical events and a descriptive summary, followed by the incidents of the German occupations and evacuations and the life of the place during the thirty months' siege. The traveler is conducted to and through the cathedral, through the badly-damaged quarters of the town, by ruined churches, and finally to the surrounding scenes of desolation left in the wake of battle.

AMERICAN GUIDE BOOK TO FRANCE AND ITS BATTLEFIELDS. By E. B. Garey, U.S.A., O. O. Ellis, U.S.A., and R. V. D. Magoffin, Ph.D. New York: The Macmillan Company, 1920. 8vo.; 331 pp.; illustrated; maps.

As Major General Leonard Wood says in his foreword, "The names of the authors guarantee not only its practical value as a traveler's guide, but its dependability in matters of civil and military history." The book avoids the interminable detail of the ordinary guide, for various and good reasons; but it answers most questions on the mechanics of travel, sketches the terrain of the war with especial reference to American participation, and furnishes facts and figures in common demand. Our soldiers and their friends will find the account of operations and the Division Histories of the greatest interest. The pictures and folding maps deserve a specific word of praise.

THE DESIGN OF ALTERNATING CURRENT MACHINERY. By James R. Barr, A.M. I.E.E. and R. D. Archibald, B.Sc. New York: Isaac Pitman and Sons. 8vo.; 496 pp.; 340 illustrations; 17 folding plates.

This substantial work, a companion volume to Barr's "Direct Current Electrical Engineering," first considers complex wave forms and harmonic analysis; transformers, alternators and converters receive a very full treatment; mechanical features, insulation, efficiencies, tests and losses are dealt with from a practical point of view and, in addition to ample illustration throughout the text, there are sixteen folding plates that ably reveal the construction of the various devices.

AUTOMOBILE BATTERY CARE AND REPAIR. By Harold P. Manly. Chicago: Frederick J. Drake and Company, 1920. 16mo.; 335 pp.; illustrated.

Wherever starting, lighting and ignition repairs are made or storage batteries handled, whether in the shop or the public or private garage, this compact handbook will prove its worth. It is a manual for the workman whose aim is to turn out satisfactory work without lost motion or wasted time: it makes him intimately acquainted with the lead-acid battery and operating conditions, with charging equipment, and with the best method of test and repair.

FORESTS, WOODS AND TREES IN RELATION TO HYGIENE. By Augustine Henry, M.A., F.L.S., M.R.I.A. New York: E. P. Dutton and Company. 8vo.; 314 pp.; illustrated.

The economist, engineer and physician, to say nothing of the general reader, are insufficiently informed regarding the influence of trees on climate, water flow, soil erosion, and the purity of air and water. While this work is specifically concerned with reforestation in Great Britain, the information and general principles are largely applicable to our own needs, and should benefit American readers. Among other branches of the subject it takes up sanatoria sites, town parks, and conditions affecting the planting of water catchment areas.

# Why the *FIRST* PNEUMATIC TRUCK TIRE was U·S·

THE United States Rubber Company in 1911 gave to the public the *first* Pneumatic Truck Tire ever built in the world, because of its unbounded faith in the future of motor truck transportation.

It built it because of its traditional policy of looking into the future—of trying to *anticipate the needs* of all kinds and conditions of *truck tire users* and building tires to *meet* them.

Before the tire users themselves become fully conscious of their needs.

Before a new tire market is even developed.

* * *

Here are the problems which the United States Rubber Company undertook to solve when it began work on a Pneumatic Tire for motor trucks:

*How to increase tire mileage—to lengthen tire life—to give the truck owner greater tire economy.*

* * *

There is a difference between building tires for *tire users* and building them for *sale.*

The United States Rubber Company has never allowed the question of sales to influence its ideals of service.

## U.S. Pneumatic Truck Tires

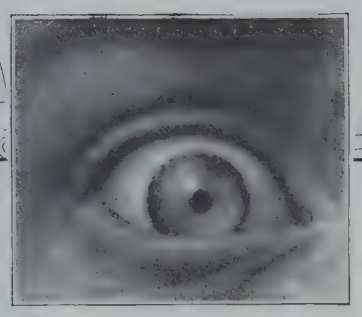
Normal eye
under right illumination



Same eye
under light with glare

# Eyes of Industry

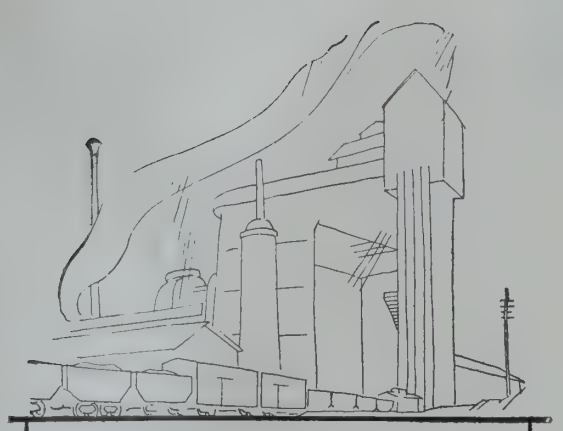
*One of many Benjamin reflectors, each designed for a special purpose*

Without sight practically all manufacturing ceases. Guard the eyes of industry and you guard industry itself. Light both guides and blinds. Too much light is like too much water—dangerous. "Avoid glare," say the foremost illuminating engineers; it causes eye strain, resulting in headaches, spoiled work, decreased production and many accidents.

Light of the proper intensity, correctly diffused and directed upon the work to be seen, is a subject that has received specialized attention from our Illuminating Engineering Department. Our success in producing lighting equipment in keeping with modern lighting standards is evidenced by the fact that hundreds of factories both large and small now use Benjamin Industrial Lighting equipment.

*Incorrect Illumination* in a factory handicaps both eye and hand. Its cost to you as determined by careful tests covering a wide range of industry is 12% *less* production, 25% *more* spoilage, and 25% *more* accidents. You cannot afford such a price for poor lighting. Change your illuminating system. It is affecting the profit side of your ledger, though you may not know it. One illumination authority says that production alone in an improperly lighted plant may be speeded up as high as 35% by the substitution of proper lights and reflectors.

Consult your own engineer, contractor or architect. Our Illuminating Engineering Department will co-operate with them gladly and without obligation. The facts are important—get them.



BENJAMIN PRODUCTS

The following are divisions of Benjamin products on which we will be glad to send information:

Industrial Lighting Division

Electrical Division (including Benjamin Two-Way Plug)

Pressed Steel Products Division

Enameled Products Division

Starrett Panel Board Division

SAFETY first—and *always*. Do you realize how much your motoring safety depends upon your brakes? Be guided by America's automotive engineers. They are keenly alive to the necessity for good brake lining. They test it—analyze it—weigh it in the balance before they specify its use.

These same experienced engineers have specified MULTIBESTOS as factory equipment on the cars and trucks shown herewith. They realize the stamina of its *interlocking* weave, its sturdy strands of wire and long-fibred asbestos. Play safe—have your brakes inspected frequently; reline them, when necessary, with MULTIBESTOS. You can depend on its long wear and high efficiency.

## A Mammoth Steam Unit and Its Work

By Sydney G. Koon, M. M. E.

RECENT reports of a remarkable run made by a forty-five-thousand-kilowatt steam turbine in a Providence, Rhode Island, lighting plant have shown figures believed to be a world record for continuous service for a unit of this size. The run covered 84 days, 11 hours, 36 minutes, or a total of 2027.6 hours. During this period the machine turned out 50,791,000 kilowatt-hours, or an average of 25,050 kilowatts over the entire period. This was just 55.7 per cent of its rating.

Attention has been drawn to the great economy of this turbine, the result having been obtained from about 1.4 pounds of coal per kilowatt hour. It is believed that the average coal consumption in central stations of the United States, per unit of power delivered, is fully double this figure. Consequently this machine is working valiantly in an effort to cut down the high cost of living.

Some of the results of this run, when compared with familiar items, make rather startling reading. The total coal burned during the run was about 71,000,000 pounds, or 35,500 net tons. At the usual bulk of 43 cubic feet per ton, this gives 1,526,500 cubic feet, or a pile of coal 305 feet long, 100 feet wide and averaging 50 feet high. To carry this coal, twenty trains of forty-five cars each would be required, each car carrying forty tons. To carry it by water would require five colliers, each of 7,100 tons cargo capacity. The United States Navy includes five coal-carrying vessels of about this unit capacity, which cost for construction an aggregate of $4,694,297.

The total steam consumption of the turbine is said to have been 609 million pounds. This represents the evaporation of 9,760,000 cubic feet of water, assuming that there was no water lost. The steam used, if at 200 pounds pressure, would have a total volume of 1,303,000,000 cubic feet, which is the equivalent of 87 Woolworth buildings. At atmospheric pressure it would form a continuous cloud of the width and height of the Woolworth building and 41 miles long.

The amount of water which was evaporated into steam was sufficient to give every one of the 1,750,000,000 inhabitants of the world a drink of water, each glass containing five and one-half ounces (one-third of a pint). This bulk of water would fill to an average depth of 6 feet 2 inches a swimming pool 30 feet wide and ten miles long, stretching from the Battery to two miles above Grant's Tomb, in New York City.

## Aluminum Dust Explosions

WE have had ample opportunity to know that organic dusts when suspended in air are highly explosive and the effects of explosion of gun powder, gun cotton, and the like, are understood for they depend upon the production of large volumes of hot gas of high critical point. This familiar explanation does not hold in many other instances. The Bureau of Mines, for example, in Technical Paper No. 152, presents data with regard to an explosion of aluminum dust, which material is largely used in the manufacture of metallic paint. Aluminum in this highly divided form burns quietly when a small quantity is ignited, but if the dust is distributed through a confined air space the combustion is violent in character. When so mixed with air, aluminum powder may be ignited by an electric spark and this has doubtless caused some of the explosions. When water is thrown on burning aluminum, hydrogen gas is evolved.

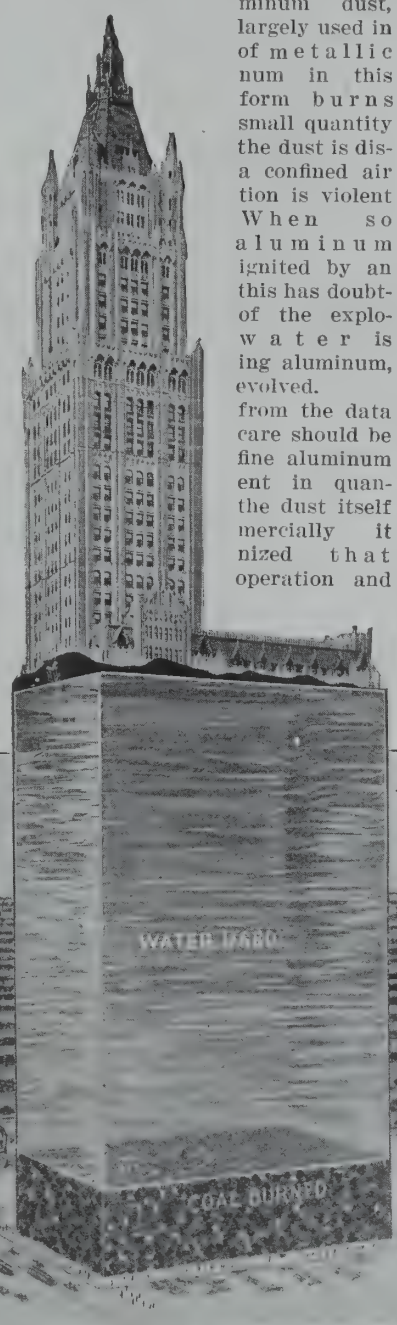
It is evident from the data presented that care should be exercised where fine aluminum particles are prescribed in quantity, and where the dust itself is prepared commercially it must be recognized that risks attend the operation and safeguards to insure proper handling should be planned accordingly.

## Photographic Developers

IT was to be expected that foreign manufacturers would endeavor to regain the American market and there have been numerous instances of advertising and other propaganda maintained for the purpose of retaining good will. In the January number of *Photographische Korrespondenz* of Vienna there is a note which refers to the progress made in America, although evidently the writer of the paragraph obtained his information from but one of our photographic periodicals since there are other manufacturers of these developers not mentioned. The article says that: "The cessation caused by the war of the exportation of photographic developers, of which Germany was the principal source of supply, caused foreigners to undertake the preparation of such substances in which attempts the German patent served as the starting point or was entirely used in the manufacture. The following developing substances similar to metol are found in the American market; monomet, serchol, phenomet, metoltoch, rhodol (monomethyl paramido-phenolsulfate), scalol, amidol, rexolon." Various claims of equality or superiority to the old German production which might be found in the advertisements of these materials are quoted in the aritcle, which concludes with a reference to the desirability of the old German metol, notwithstanding the large number of competitors which the war has introduced.

## Water-Proofing

IN a series of tests designed to improve the waterproofing of materials such as propellers for airplanes, the Forest Products Laboratory has demonstrated that when aluminum leaf can be used with a lacquer or varnish which cements it to the wood, the resulting coating is twenty-five times more effective than any other process for water-proofing wood. The leaf can be applied quickly and the cost is not prohibitive. The necessity for water-proofing a propeller is illustrated by the fact that at times eighty per cent of the propellers produced in France were rejected by the pilots, because of a lack of balance, much of which could be traced to unequal absorption of moisture. Of course, the same method of water-proofing is applicable to other appliances.



The coal burned would fill 50 feet of the Woolworth Building; the water used would fill the rest of the main structure to within a few feet of the tower's base. The coal would require twenty trains of forty-five cars each for its transport, and the steam generated, at working pressure, would fill 87 Woolworth Buildings, as indicated by the comparison of bulk at the lower left.

What the 84-day run of the big turbine means in terms of coal and water

## The Einstein Judges

AFTER a rather longer interval than we had anticipated, we are now able to announce the identity of the Einstein Judges. The decision as to the size of this committee we have made after careful consideration; and while we believe it to be a wise one, we realize that in some respects it may be a surprising one, and that the grounds on which it is based ought to be stated.

We are assured with complete certainty that the competition for the five-thousand-dollar-prize will be very keen, and that many essays will be submitted which, if they bore the names of their authors, would pass anywhere as authoritative statements. The judges will confront a task of extraordinary difficulty in the effort to determine which of these efforts is the best: and we believe the difficulties are such that multiplication of judges would merely multiply the obstacles to an agreement. It is altogether likely that the initial impressions of two or three or five judges would incline toward two or three or five essays, and that any final decision would be attainable only after much consultation and discussion. It seems to us that by making the committee as small as possible while still preserving the necessary feature that its decision represent a consensus, we shall simplify both the mental and the physical problem of coming to an agreement. We believe that the award should if possible represent a unanimous decision, without any minority report, and that such a requirement is far more likely to be met among two men than among three or five. At the same time, the bringing together of two men and the details of general administration of their work together are far simpler than if there were three or five. So we have finally decided to have but two judges, and in this we have the endorsement of all the competent opinion that we have consulted.

At the same time, a strict interpretation of the postal laws forbids that we introduce into the contest, by any suggestion of dividing the prize, what the Post Office looks upon as an "element of chance." It is therefore necessary to make provision against the remote contingency that the judges be really unable to reach an agreement. In this event, our own Einstein Prize Essay Editor will cast the deciding vote, between the two essays favored by the individual judges. Aside from this, of course, the SCIENTIFIC AMERICAN will have no voice in the award.

The gentlemen who have consented to act as judges are Professors Leigh Page and Edwin Plimpton Adams, of the departments of physics of Yale and Princeton Universities, respectively. Both are of the younger generation of physicists that has paid special attention to those phases of mathematics and physics involved in the Einstein theories, both have paid special attention to these theories themselves. We are gratified to be able to put forward as judges two men so eminently qualified to act. We feel that we may here appropriately quote Professor Page, who says in his acceptance: "As the large prize offers a great inducement, I had thought of entering the contest. However I realize that not many people in this country have made a considerable study of Einstein's theory, and if all who have should enter the contest, it would be difficult to secure suitable judges." Without any desire to put the gentleman in the position of pleading for himself, we think this suggests very well the extent to which the SCIENTIFIC AMERICAN, the contestants, and the public at large, are indebted to Professors Page and Adams for their willingness to serve in the difficult capacity of judges.

## Aerial Stunts and Public Safety

IT was inevitable that, in his quest of the novel and sensational, the photographer would, sooner or later, enlist the services of the airplane; and it was probable that, in his effort to secure pictures of a sensational character, he would ultimately expose both the pilot and the public to very serious risks. Evidence of this was seen during the recent contests for the America's Cup off Sandy Hook, when the airplanes repeatedly flew at dangerously low altitudes over the fleet of yachts and excursion boats that were crowded around the starting line, some of them threading their way through the fleet at an elevation of only a few feet above the water.

It is well understood that if a skilful pilot is flying at considerable height, he can pull his machine out of a dangerous situation such as a side slip, a nose spin, or a tail spin; whereas, at a low altitude a crash is inevitable. The peril of taking aerial photographs of sporting events lies in the temptation to descend to low altitudes and slow down the flying speed—a dangerous combination should anything go wrong with pilot or motor. As it was, there were several forced descents during the Cup races and it was more "by luck than good shooting" that no fatalities occurred.

It was reserved for the attempt to photograph the final match for the Tennis Championship at Forest Hills to demonstrate, in tragic fashion, the peril of close-up aerial photography. Two veteran airmen of the war, a pilot and a photographer, while circling outside the courts on which Tilden and Johnston were playing the final, suddenly went into a nose-spin and crashed a few hundred feet from the crowded grandstands. There is no doubt in the mind of the writer, who witnessed the fall, that these experienced men were the victims of their zeal to secure good close-up photographs—their maneuvers after they reached the grounds from Mitchel Feild and the behavior of the machine at the turns and in the fatal plunge confirm this opinion.

When the machine first reached the vicinity of the courts it was at a height of apparently twelve to fifteen hundred feet. After circling the field, it came down to about nine hundred and finally to about five hundred feet. The pilot then throttled down to a speed that was slow even for a Curtiss JN-4. At this low elevation and slow speed the pilot closed in on the field, circling a few hundred feet outside of the court and grandstands. He never passed over the field at this elevation, the press statements to the contrary notwithstanding.

The flight of the machine when throttled down was noticeably unsteady, and the banking at the turns seemed to be excessive for the speed. Finally, off the northwest corner of the court, a sharp turn to the left was made, with an exceptionally high bank. The machine appeared to side slip, then dived steeply and immediately went into a nose-spin, and so low was the elevation that there was no possibility of recovery. Both men were killed.

The moral of this distressing accident, which has robbed the country of two experienced airmen, is that the taking of close-up aerial photographs of sporting events at which large crowds of people are assembled should be absolutely prohibited. Had the machine gone out of control a few hundred feet nearer the courts, it might well have fallen among the eight or ten thousand people on the stands, in which event a score or more of lives might have been lost and twice that number of people injured.

Furthermore these aerial pictures of sporting events are not worth the danger incurred. At the best they fail to show any illuminating detail of the play, and for practical purposes they are greatly inferior to the superb pictures which can be secured from the ground or from the top of neighboring structures. The Army and Navy officials should put a ban upon photographic stunts of this kind and the State and Municipal authorities should follow suit.

## The Importance of Negative Results

ONE aspect of recent scientific developments which does not appear to have received its deserved attention, is the pointed lesson we have received regarding the importance of negative results in experimental investigations. It would be useless to deny the fact that the worker in science welcomes more heartily positive findings than the establishment of a negative conclusion. Science may be impersonal, abstract; but the scientific investigator is perforce concrete, human. He may set before him as an ideal an absolute impartiality, a complete freedom from bias, from desire to find anything but the truth, whether palatable or not. But ideals aside, he cannot help being in some degree influenced by a variety of factors, with the general result that he will on the whole give preference, in his selection of a task, to problems likely to lead to positive results.

It is therefore well that we should be reminded, from time to time, that negative results are always important, and, in certain instances, have proved of the very highest order of importance. Thus the foundation of the edifice reared by Einstein is the Michelson-Morley experiment, a classical piece of work conducted with consummate skill and care; the very fact that its results were negative necessitated the most extreme precautions, and none but expert experimenters would have been qualified to give us a report with the degree of reliability demanded in just such cases, where the effect looked for is either small or null.

It is interesting in this connection to note some of the other classical examples of negative results in experiments of superlative importance. There is, first of all, the accumulated evidence of numerous attempts to build a perpetual motion machine, resulting invariably in failure. It may be urged that these chimerical attempts were of necessity foredoomed to failure in view of the law of conservation of energy. But we may equally well say that the evidence of these consistent failures is one of the data on which we base our conviction in the law of conservation of energy. Similarly, the common experience that it is impossible to run an engine by the aid of the heat contained in a cold body (for example, to run an ocean liner by heat drawn from the sea) may be regarded as the basis of the so-called second law, the law which indicates the upper limit of efficiency attainable in a heat engine.

The mathematician too has a little group of negative results of his own that are of more than passing interest. For a great many centuries he tried to solve the classical problems of duplicating the cube, trisecting the angle, and squaring the circle; until his repeated failures led him to the conviction that the problems were not to be solved within the terms proposed. But he did not stop here; he has carried his investigations to the point where he can prove the impossibility of doing any of these things within the terms proposed, and can now say, not merely that failure to do them indicates their impossibility, but that they are impossible and he knows why. This categorical establishment of a negative result is something seldom met in other fields than the mathematical, and in fact enables the mathematician to escape much of the implicit sting of the failure to achieve something positive.

Some years ago we would have added to the list of classical negative results the attempts at transmuting elements. Today we have stricken out this item and placed it among the array of the accomplished facts of science, though to be sure the transmutation realized is not that active operation dreamed of by the alchemists, but a passive process over which we seem to have little or no control.

Lastly, of famous negative results, must be mentioned our failure to produce life by spontaneous generation. We are so accustomed, today, to the idea that life springs from life alone, that we hardly realize how to an earlier generation there seemed nothing in any way fanciful or improbable in the supposition that maggots, for example, originated, directly and without intervention of parents, from decaying refuse.

## Engineering

**Canada's New Highways.**—Five million dollars will be spent this year in making better main highways of Canada through Federal and provincial grants. Of this amount the Dominion Government will contribute $2,000,000 and the provincial governments $3,000,000. This is the first year in which the road money has been available, and in view of the time taken in preparing plans the initial year's outlays will not be so heavy as in some succeeding years.

**Ashes as Road Material.**—The city of LaCrosse, Wisconsin, is to continue the plan adopted about two years ago of covering the city streets with ashes. By this plan the sandy and almost impassable streets are converted into smooth, hard driveways. In the last two years the Board of Public Works has thus improved about ten miles of streets, using the ashes from residences and factories. Between 30 and 35 loads of ashes (two yards per load) are required for the improvement of one block of sandy street, at a cost of a little over $14 per block for haulage only, or about $186 per mile, as against the old practice of paying to have them hauled and dumped on waste land.

**Pressure of Concrete on Forms.** — A pressure-gage devised by A. T. Goldbeck and used for the last few years in measuring earth pressures behind retaining walls and under fills, has been applied successfully to the measurement of the pressure of concrete on forms embedded therein. The gage consists essentially of an air-tight metal cell having a circular weighing face 10 sq. inches in area, according to the *Engineering News-Record*. The concrete pressure against the face of the cell is balanced by admitting compressed air to the inside of the cell. When the pressures are balanced an electrical contact is broken which extinguishes a light and signifies that the pressure shown on the gage connected with the air pipes is equal to the pressure of the concrete.

**Hydraulic-Fill Dams.** — The hydraulic method of dam construction has great advantages, but many dams built by it have failed. As often built the center of the dam is composed of a clay core completely water-tight but very wet as a result of the method of construction, and so completely water-tight that it is incapable of permitting its own drainage. This soft core exerts the pressure of a liquid of high specific gravity upon the toes, and tends to push them out. Most of the failures of this type appear to have been attributable to this pressure, continues Allen Hazen, in the *Proceedings of the American Society of Civil Engineers*. The commonly used method of placing the core results in an exceedingly fine-grained material, but though this is very desirable from the standpoint of a water-tight dam, it may be that the extreme tightness is secured at the expense of stability. For success in using the hydraulic method, it is necessary either to increase the dimensions of the toes until they are large and heavy enough to resist the full liquid pressure of the core, or else to handle the core material so that the finest particles are wasted, leaving only the largest ones, thereby increasing the grain size to a point where drainage can be secured, while remaining sufficiently impervious for practical purposes.

**Local Magnetic Disturbances** of intensity equalled nowhere else in the world were observed for some years by one Professor Leyst in the vicinity of Koursk, Russia. He attributed this to the presence of large undiscovered bodies of iron ore. His data have been rescued and transported to Sweden, where they have been worked over, with the result that it appears the deposits in question must be two in number, each 108 kilometers long, and the largest in the world.

## Astronomy

**Spectrum of Jupiter.**—Mr. V. M. Slipher reports that, with the aid of dyes for sensitizing dry plates for the lower spectrum, he has been able to extend the photographic spectra of the planets into lower wavelengths than were formerly accessible. He has presented to the American Astronomical Society the results of observations of the spectrum of Jupiter, which reveal several new bands and lines due to the selective absorption of the planet's atmosphere.

**Polariscopic Observations During a Lunar Eclipse.** —M. P. Salet, of the Observatory of Paris, reports that the light of the moon during the total eclipse of May 3, 1920, was examined for polarization at that observatory, with Savart polariscopes placed before the eyepiece of a telescope. The different parts of the earth's shadow on the moon showed no trace of polarization. This result does not, therefore, support the observations of Arago, during a lunar eclipse in 1844, and of Zantedeschi and Freeman during subsequent eclipses, all of these observers having reported that they found evidences of polarization in the light of the eclipsed moon.

**The First Astronomical Photographs in Colors** are said to have been those obtained by MM. Gimpel and Touchet of the total lunar eclipse of May 3, 1920, at the observatory of the Astronomical Society of France, in Paris. As this was a pioneer undertaking, no data were available as to the proper time of exposure. The camera was attached to the small equatorial of the observatory, and pictures were taken with exposures ranging from 3 to 40 minutes throughout totality. All proved to be under-exposed except that with the longest exposure, which showed different shades of red coloration and several details of the lunar surface. At the next lunar eclipse the photographers hope to use the great equatorial of the Meudon observatory, which should produce as satisfactory results with an exposure one-twenty-seventh as long. Supersensitized Lumière autochrome plates were used.

## Industrial Efficiency

**Fuel Oil for Railroads.**—The great scarcity of coal has caused the Paris, Lyons, and Mediterranean Railway Company to transform some of its motive power from coal to fuel oil consumption, which is about to be followed by the Chemin de Fer de l'Etat, or State-owned Railway, and engines at its shops at Saintes are now undergoing changes for experimental purposes. Much attention is being directed to the announcement that the first-named railway company is planning to equip 200 locomotives for fuel oil and install numerous storage reservoirs of from 40 to 100 tons' capacity at various points on its lines.

**Germany's Shortage of Gasoline.**—In a recent general meeting of the Society of German Motor Car Manufacturers complaint was made that sales are badly blocked by the shortage of gasoline; that the importation from the United States is, in spite of very considerable orders most unsatisfactory seemingly on account of an enormous consumption in the United States; that it is hoped that Roumania will soon be able (as in former times) to again take up its gasoline export to Germany. In the course of the meeting it was further stated that it was planned to work hand in hand with the Austrian automobile industry concerning all economic questions.

**Pulpwood of Canada.** — Louis Piche, Provincial Forester, estimates that in Quebec there are 360,000,000 cords of all pulpwoods. Of this amount, there are 155,000,000 cords of available spruce and balsam which, at the present rate of cutting, namely, 3,000,000 cords per year, would give about 52 years' supply. It is estimated that there are, in Ontario, 250,000,000 cords of spruce and balsam. Of this it is estimated that at an early date the cut will be 1,500,000 cords, which indicates 67 years' supply. New Brunswick, with 36,000,000 cords of spruce and balsam, and an annual cut of 1,250,000 cords, has sufficient for a twenty-nine years' supply.

**Sea Lion Leather.** — Large numbers of sea lions on the British Columbia coast which destroy annually vast quantities of fish food may be slaughtered and their hides placed on the world's leather market, if a proposition which comes from Premier Oliver and has the approval of many experienced fishermen, is carried out. The sea lion weighs from 2,000 to 2,500 pounds, the hides being nearly an inch thick. These hides make a tough and durable rough leather such as is used in workmen's gloves and in saddles. It is stated that these animals will eat 50 pounds of fish in a day. Four hunters recently killed several hundred sea lions in one day in the Charlotte Islands.

**Traveling Railway Car Exhibit.**—One method of advertising, as effective as the use of motion pictures, is the railway car specially fitted to display merchandise, according to British business men. Accompanying this car (or cars) should be a salesman able to speak the language of the country where the car is traveling and capable of demonstrating the articles exhibited. Even if parts of a model of an agricultural implement or machine be shown, the salesman ought to be able to get a complete machine from a central agency or warehouse in the country where the exhibit is being made and show the practical working of the machine. It appears a demonstration would be a good selling argument. However, most manufactures are not so bulky or difficult to handle as farm machinery. To make sure of reaching business men, farmers and artisans, the coming of the Railway Car Exhibit is widely advertised in newspapers and on bulletin boards. Thus far the results in attendance and interest manifested have been beyond the most sanguine hopes of the promoters of the scheme.

## CONDITIONS FOR THE $5,000 PRIZE EINSTEIN ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essa ymust be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Essay Editor will cast the deciding vote.

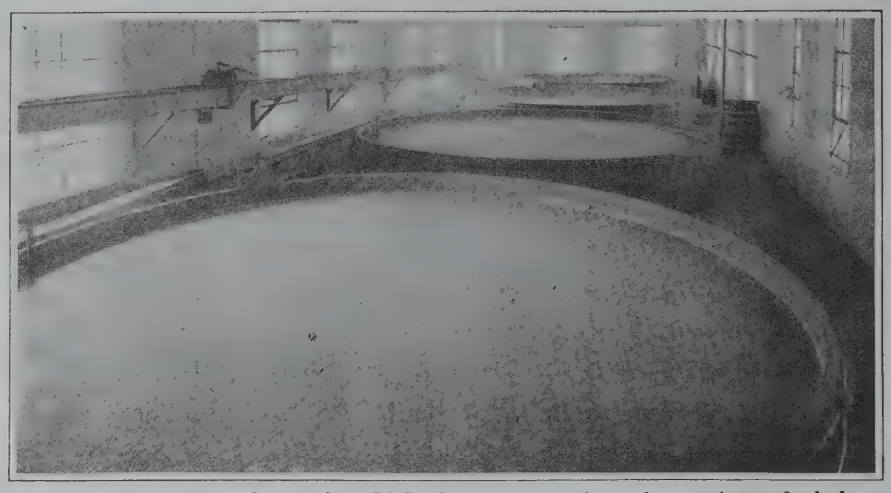
# Shall the Corn Fields Run Our Cars?

## The Possibilities of Synthetic Fuels, and the Source of the Alcohol to Make Them

By Robert G. Skerrett

ALCOHOL will inevitably play a part of steadily increasing importance in our economic life. For many years it has been indispensable to the industrial arts in one way or another, but from now on it will figure more and more in furnishing heat and motive energy. Indeed, the students of the subject realize that we cannot begin too soon to develop our sources of alcohol and to adapt our internal-combustion engines and other apparatus to the use of this liquid fuel.

If one will take the trouble to study the array of advertising matter having to do with automotive vehicles it will be plain that the engineer and the inventor are busy trying to get an augmented service out of a given quantity of "gas." This end is being sought either by the development of auxiliaries of a wide variety or by modifications of the engines so that they can work to better advantage when fed gasoline of lower quality. This procedure is, in a sense, a sop to expediency and does not scientifically strike right at the kernel of the problem.



**Part of a group of vats in which the fermentation of corn into alcohol is carried on**

The manufacture of internal-combustion engines, insofar as the art is directly related to the utilization of gasoline, is in much the same state as was the fabrication of heavy cannon before the evolution of modern smokeless propellants. In the days gone, the ordnance engineer had to design his gun so that it would be strong enough to withstand the gases suddenly and violently generated by black powder. The controlling factor was a mechanical mixture of saltpeter, charcoal, and sulfur. As far as lay in their power, the metallurgist and the gunmaker joined forces, and together larger rifles were turned out capable of holding the explosive gases safely in check. But there was a limit to progress in the matter of weapons using black powder just as there is in the building of engines relying entirely upon gasoline for their impulse.

Next came smokeless powder, a chemical product, and from then on the ordnance engineer was unfettered: he can now pattern his rifle to give definite performances in the way of range and initial velocity. Having designed his gun, he turns to the man of the laboratory to provide a smokeless propellant which will function in complete harmony with the physical characteristics and the intended purpose of each type of cannon. And, let it be said, that in the same general manner we must cease to rely upon gasoline, pure and simple, as a primary source of power and, instead, adopt composite fuels which the chemist will compound for us to meet stated conditions. In these alcohol is sure to figure conspicuously.

Six years ago, a synthetic fuel was brought out in South Africa and subjected to a series of tests which gave excellent results. The fuel was made up of about 60 per cent alcohol, 39 per cent ether, 1 per cent ammonia, and ½ per cent of arsenious acid. The purpose of the ether was to increase the "kick" and to make it possible to start an engine when cold. The ammonia neutralized the corrosive exhaust of the alcohol so that it would not injure exposed metal surfaces, and the arsenic was to denature the mixture.

A synthetic fuel invented in this country has been perfected for airplane service. This is composed of 38 parts of alcohol, 19 parts benzol, 4 parts toluol, 30 parts gasoline, 7½ parts ether, and 1½ parts of some ingredient which is not disclosed, probably a denaturant. The fuel, during a trial period of several weeks, proved to be more economical than high-test aviation gasoline. The carbon deposit was less than is normally the case, and there was a reduction in the amount of lubricating oil required. Composite fuels, as we have them now, are helping to carry us along during the interval of transition from the out-and-out gasoline engine to a motor which may be developed that will be able to use straight or nearly straight alcohol. In either event, the result will be the evolution of engines having superior characteristics; and the fuel, synthetic or otherwise, will be prepared to suit the motor instead of largely dominating its mechanical get-up as now.

It is a matter of pretty common knowledge among those familiar with the liquid fuel used in automobiles and trucks that benzol is added to some grades of gasoline to improve their deficient "kick," and this ingredient is said to check carbon deposits. Toluol also augments the energy factor. Both benzol and toluol are coal-tar derivatives, and can today be had in immense quantities from our by-product coke ovens and from up-to-date gas houses. But even so, the layman may wonder where we are going to get all of the alcohol that may be needed when we come to depend less and less exclusively upon gasoline.

Hitherto, most of our so-called industrial alcohol has been obtained from sugar-mill waste, i.e., the well-known blackstrap molasses. The amount of this basic raw product is decreasing, mainly because the refiners have brought into play processes which make it possible for them to secure from the molasses various marketable syrups to satisfy the popular sweet tooth. True, low-grade molasses can still be had from the sugar mills of the Far East and other remote sources, but this entails the service of special tank steamers and the added costs of transportation. How, then, are we to produce the great measure of alcohol which we shall want ere long?

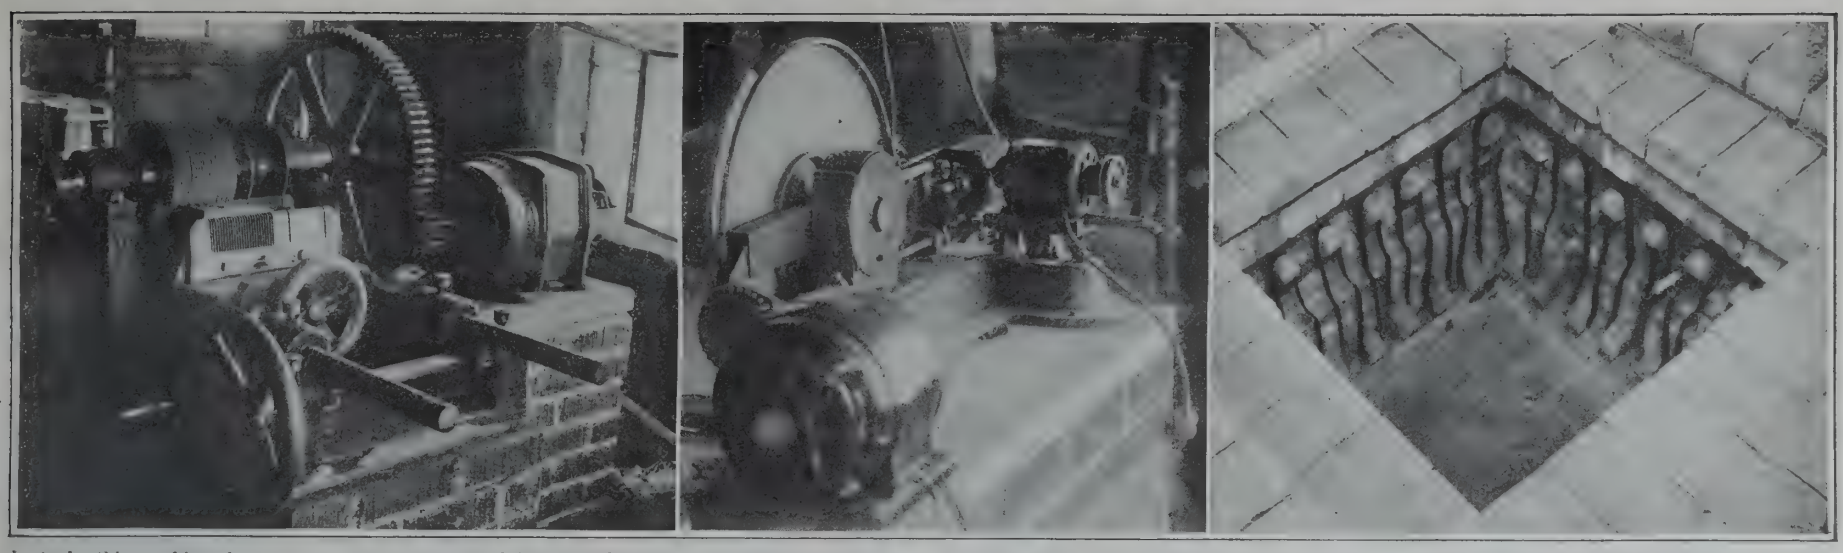
**Three steps in the extraction of alcohol from corn**



*Left:* In this machine the sections of shale are sawed into pencil-like strips for subsequent shaping into needles. *Center:* The grinding machine for shaping the needles. *Right:* The electric kiln in which the shaped needles are heated to 2,000° Fahrenheit, in order to give them the proper hardness. Note the strips around the sides of the kiln, which comprise the heating element

**From clay to phonograph needle via various machines and the tremendous heat of the electric furnace**

## Clay Needles for the Talking Machine

**By Allen P. Child**

THERE seems to be no end to the various kinds of phonograph needles. Playing records with a chip of a brick is the latest in phonograph needles—and the invention of an Iowa man. It is claimed that this needle of clay will play, with a very clear tone and with little surface noise, at least 200 times.

The needles are made from a dark red or chocolate colored shale. As the shale has practically no grain, and no grit is present, it is found that a very high polish is taken on where it comes into contact with the record. In making the needle the shale is cut from a bank in sections which are as nearly square as possible and each piece measures about 6 inches. The shale is brought from the clay banks and the sections are stored in sacks coated with paraffine. These sacks serve to keep the air away from the shale as it is liable to air check if exposed to the air when in a moist condition.

The sections of shale are then placed in an electric drier where it is dried very slowly. After thoroughly dried each section is clamped in a vise and is run through a saw which cuts it into pencil shaped strips 3¼ inches in length and ⅛-inch square. The shale pencils are placed on a pallet and are fed automatically into the needle machine where they are pushed out through the head where they come into contact with a grinding wheel with 10,000 revolutions per minute. As they leave the head each pencil revolves at about 600 revolutions per minute. The grinding wheel turns each pencil to a perfectly round needle.

After projecting about ¾ of an inch each pencil comes in contact with another grinder which is set sideways and a perfect point is turned on the needle. A high speed cutting wheel trims the needles to the required length after they have left the grinding machines.

After being placed in fire clay containers they are put in an electric kiln. In the kiln the heat is gradually increased to 2,000 degrees Fahrenheit. Needles are removed when the kiln has cooled sufficiently. The shale vitrifies perfectly at this temperature and is of a dark red color. If not over burned in the kiln the needles are of exceptional hardness.

## The Rocking of a Tall Chimney

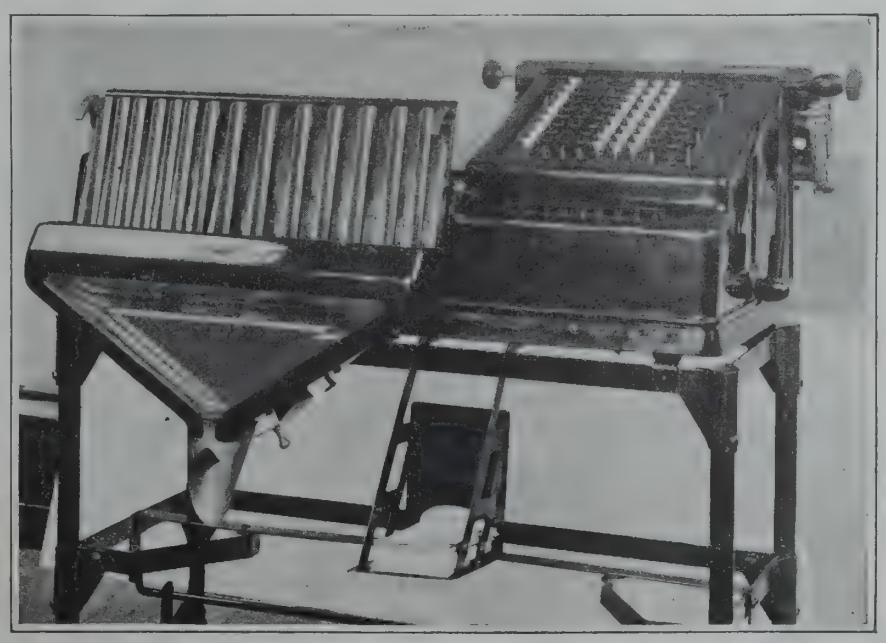
THERE used to be, and possibly still is, in certain quarters of Glasgow, Scotland, where are two of the tallest chimneys, a belief that the tops of those chimneys in high gales of wind swayed as much as 3 feet each way. Both these chimneys are built of brick. The oscillation of a chimney shaft taller than either of the Glasgow ones, built of reinforced concrete, at Saganoseki, Japan, has been carefully watched and measured by a Japanese engineering professor, says a writer in a British trade paper. The shaft is 570 feet in height and has a diameter inside at the top of 26 feet 3 inches. The wind velocities during the observations ranged from one mile per hour, a gentle zephyr, to a hurricane of 78 miles an hour. According to the professor the amplitude of the vibration at the top in a 50-mile wind was no more than 1 inch, that is to say something and nothing, about half an inch each way.

In the 78-mile wind, however, the amplitude was 7.32 inches as a maximum, and curiously enough the movement was not in the direction in which the wind was blowing, but af right angles to that direction. The professor calculates that in a gust of 110 miles an hour, which not infrequently occurs, the amplitude would be at least 15 inches. It is interesting further to note that the time taken for each complete vibration was practically the same whatever the velocity of the wind, the range being merely from 2.52 seconds to 2.56 seconds.

## Fuel Value of Wood

THE fuel value of wood has been the subject of more than one discussion and the following therefore may be of interest. A ton of coal may be taken as the equivalent in heating value of one cord of heavy wood, such as hickory, ash, oak, elm, beech, locust, birch, cherry, long-leaf pine, and hard maple. One and a half cords are required of short-leaf pine, Douglas fir, red gum, sycamore, soft maple, and western hemlock to equal a ton of coal, while in the case of cedar, cypress, catalpa, basswood, redwood, poplar, spruce, and white pine, two cords are equivalent to one ton of coal. Resin in wood gives twice as much heat as the wood itself, which accounts for the fact that the pines and firs have more heating power per ton than non-resinous wood.

It is to be understood that fuel value depends not alone upon heating power, but upon rapidity of burning, ease of ignition, minimum smoke, and uniformity in heat. Pines give a quick, hot fire and are consumed more rapidly than birch, birch giving a more intense flame than oak, while oak is noted for the steady heat it produces.



**This machine, based on the general principle of the adding machine, reduces the erstwhile tedious task of preparing the payroll to a simple mechanical operation**

## Putting the Payroll on an Automatic Basis

**By Charles Abbott Goddard**

MANY are the mile posts of progress along the course which has transformed the old-time office where all writing and computing were done by hand, to the business workshop of today with its battery of typewriters and adding machines, its equipment for duplicating letters and forms of all sorts, its steel filing cabinets, and its private telephone switchboard. "Push the button and the machine does the rest," is a principle that has had marvelous adaptation to every phase of business routine.

A product of this age of office efficiency which has proved its worth is a machine which adds making out the payroll to the long list of business details now accomplished with mechanical ease. For years one of the most trying tasks for every company with a large number of employes has been making up the weekly or monthly payroll.

Although the advent of the adding machine brought considerable relief in this work, there were still many chances for mistakes in handling the cash. Checking up a great number of envelopes already filled to find the error was a tedious business at best. The adding machine assured the accurate adding of the payroll, providing the necessary sub-total and totals, but its usefulness ended when it came to denominating the payroll and actually filling up the envelopes.

Now comes a machine that solves all of the paymaster's problems at once. It operates like a standard adding machine in so far as it adds and lists the payroll, giving the grand total and sub-totals. But it does not stop there. The next step it performs is to denominate the payroll, that is, to indicate exactly how many twenties, tens, fives, ones, half dollars, quarters, dimes, nickels, and cents must be drawn to pay correctly. This is so long and tedious a job that many cashiers and paymasters simply approximate these denominations, carry an extra change account and balance the cash when the payroll is finished. This entails extra bookkeeping and the possibility of having to hold up the entire payroll to send out for more coins if those of any denomination are exhausted.

The payroll machine eliminates this entire problem by indicating instantly when it gives the payroll total, in just what denominations this amount must be drawn to pay each item correctly. The cashier can thereby draw the total payroll amount in exactly the denominations that will be needed, knowing that when the last envelope is filled the last cent will be used.

This remarkable machine goes still further. When the money is on hand the scheduling device is replaced by a coin tray into which all coins, gold or silver, are placed. The operator then runs off each payroll item on a keyboard similar to the standard adding machine keyboard. Each time the operator lists an item and pulls the handle the machine automatically counts out the correct amount of coin and drops it into the employe's envelope, at the same time making a permanent

(*Continued on page 284*)

# New Concepts of the Past Century

## The Change in Outlook Since Classical Days, Which Makes Non-Euclidean Geometry a Possibility

### By the Einstein Prize Essay Editor

THE science of geometry has undergone a revolution of which the outsider is not informed. The classical geometer regarded his science from a narrow viewpoint, as the study of a certain set of observed phenomena—those of the space about us, considered as an entity in itself and divorced from everything in it. It is clear that some things about that space are not as they appear (optical illusions), and that other things about it are true but by no means apparent (the sum-of-squares property of a right triangle, the formulæ for surface and volume of a sphere, etc.). While many things about space *are* "obvious," these need in the one case disproof and in the other discovery and proof. With all their love of mental processes for their own sake, it is then not surprising that the Greeks should have set themselves the task of proving by logical process the properties of space, which a less thoughtful folk would have regarded as a subject only for observational and experimental determination.

But, abstract or concrete, the logical structure must have a starting point. It has been pointed out in these columns that the simplest words cannot be defined in terms of anything still simpler. In any logical structure they must therefore stand undefined. Equally, the simplest facts cannot be proved in the absence of simpler facts to cite as authority. If we are to have a logical structure of any sort, we must begin by laying down certain terms which we shall not attempt to define, and certain statements which we shall not try to prove.

The classical geometer sensed the difficulty of defining his first terms. But he supposed that he had met it when he defined these in words free of technical significance. "A point is that which has position without size" seemed to him an adequate definition, because "position" and "size" are words of the ordinary language with which we may all be assumed familiar. But today we feel that "position" and "size" represent ideas that are not necessarily more fundamental than those of "line" and "point," and that such a definition begs the question. We get nowhere by replacing the undefined terms "point" and "line" and "plane," which really everybody understands, by other undefined terms which nobody understands any better.

In handling the facts that it was not convenient to prove, the classical geometer came closer to modern practice. He laid down at the beginning a few statements which he called "axioms," and which he considered to be so self-evident that demonstration was superfluous. That the term "self-evident" left room for a vast amount of ambiguity appears to have escaped him altogether. His axioms were axioms solely because they were obviously true.

### Laying the Foundation

The modern geometer meets these difficulties from another quarter. In the first place he is always in search of the utmost possible generality, for he has found this to be his most effective tool, enabling him as it does to make a single general statement take the place and do the work of many particular statements. The classical geometer attained generality of a sort, for all his statements were of *any* point or line or plane. But the modern geometer, confronted with a relation that holds among points or between points and lines, at once goes to speculating whether there are not other elements among or between which it holds. The classical geometer isn't interested in this question at all, because he is seeking the absolute truth about the points and lines and planes which he sees as the elements of space; to him it is actually an object so to circumscribe his statements that they may by no possibility refer to anything other than these elements. Whereas the modern geometer feels that his primary concern is with the fabric of logical propositions that he is building up, and not at all with the elements about which those propositions revolve.

It is of obvious value if the mathematician can lay down a proposition true of points, lines and planes. But he would much rather lay down a proposition true at once of these and of numerous other things; for such a proposition will group more phenomena under a single principle. He feels that on pure scientific grounds there is quite as much interest in any one set of elements to which his proposition applies as there is in any other; that if any person is to confine his attention to the set that stands for the physicist's space, that person ought to be the physicist, not the geometer. If he has produced a tool which the physicist can use, the physicist is welcome to use it; but the geometer cannot understand why, on that ground, he should be asked to confine *his* attention to the materials on which the physicist employs that tool.

It will be alleged that points and lines and planes lie in the mathematician's domain, and that the other things to which his propositions may apply may not so lie—and especially that if he will not name them in advance he cannot expect that they will so lie. But the mathematician will not admit this. If mathematics is defined on narrow grounds as the science of number, even the point and line and plane may be excluded from its field. If any wider definition be sought—and of course one must be—there is just one definition that the mathematician will accept: Dr. Keyser's statement that "mathematics is the art or science of rigorous thinking."

The immediate concern of this science is the means of rigorous thinking—undefined terms and definitions, axioms and propositions. Its collateral concern is the things to which these may apply, the things which may be thought about rigorously—everything. But now the mathematician's domain is so vastly extended that it becomes more than ever important for him to attain the utmost generality in all his pronouncements.

One barrier to such generalization is the very name "geometry," with the restricted significance which its derivation and long usage carry. The geometer therefore must have it distinctly understood that for him "geometry" means simply the process of deducing a set of propositions from a set of undefined primitive terms and axioms; and that when he speaks of "a geometry" he means some particular set of propositions so deduced, together with the axioms, etc., on which they are based. If you take a new set of axioms you get a new geometry.

The geometer will, if you insist, go on calling his undefined terms by the familiar names "point," "line," "plane." But you must distinctly understand that this is a concession to usage, and that you are not for a moment to restrict the application of his statements in any way. He would much prefer, however, to be allowed new names for his elements, to say "We start with three elements of different sorts, which we assume to exist, and to which we attach the names A, B and C—or if you prefer, primary, secondary and tertiary elements—or yet again, names possessing no intrinsic significance at all, such as ching, chang and chung." He will then lay down whatever statements he requires to serve the purposes of the ancient axioms, all of these referring to some one or more of his elements. Then he is ready for the serious business of proving that, *all his hypotheses being granted*, his elements A, B and C, or I, II and III, or ching, chang and chung, are subject to this and that and the other propositions.

### The Rôle of Geometry

The objection will be urged that the mathematician who does all this usurps the place of the logician. A little reflection will show this not to be the case. The logician in fact occupies the same position with reference to the geometer that the geometer occupies with reference to the physicist, the chemist, the arithmetician, the engineer, or anybody else whose primary interest lies with some particular set of elements to which the geometer's system applies. The mathematician is the tool-maker of all science, but he does not make his own tools—these the logician supplies. The logician in turn never descends to the actual practice of rigorous thinking, save as he must necessarily do this in laying down the general procedures which govern rigorous thinking. He is interested in processes, not in their application. He tells us that if a proposition is true its converse may be true or false or ambiguous, but its contrapositive is always true, while its negative is always false. But he never, from a particular proposition "If A is B then C is D," draws the particular contrapositive inference "If C is not D then A is not B." That is the mathematician's business.

The mathematician is the quantity-production man of science. In his absence, the worker in each narrower field where the elements under discussion take particular concrete forms could work out, for himself, the propositions of the logical structure that applies to those elements. But it would then be found that the engineer had duplicated the work of the physicist, and so for many other cases: for the whole trend of modern science is toward showing that the same background of principles lies at the root of all things. So the mathematician develops the fabric of propositions that follows from this, that and the other group of assumptions, and does this without in the least concerning himself as to the nature of the elements of which these propositions may be true. He knows only that they are true for any elements of which his assumptions are true, and that is all he needs to know. Whenever the worker in some particular field finds that a certain group of the geometer's assumptions *are* true for his elements, the geometry of those elements is ready at hand for him to use.

Now it is all right purposely to avoid knowing what it is that we are talking about, so that the names of these things shall constitute mere blank forms which may be filled in, when and if we wish, by the names of any things in the universe of which our "axioms" turn out to be true. But what about these axioms themselves? When we lay them down, in ignorance of the identity of the elements to which they may eventually apply, they cannot by any possibility be "self-evident." We may, at pleasure, accept as self-evident a statement about points and lines and planes; or one about electrons, centimeters and seconds; or one about integers, fractions, and irrational numbers; or one about any other concrete thing or things whatever. But we cannot accept as self-evident a statement about chings, changs and chungs. So we must base our "axioms" on some other ground than this; and our modern geometer has his ground ready and waiting. He accepts his axioms on the ground that it pleases him to do so. To avoid all suggestion that they are supposed to be self-evident, or even necessarily true, he drops the term "axiom" and substitutes for it the more colorless word "postulate." A postulate is merely something that we agree to accept, for the time being, as a basis of further argument. If it turns out to be true, or if we can find circumstances under which and elements to which it applies, any conclusions which we deduce from it by trustworthy processes are valid within the same limitations. And the propositions which tell us that, *if* our postulates are true, such and such conclusions are true—they, too are valid, but without any reservation at all!

### What May We Take for Granted?

But how does the geometer know what postulates to lay down? One is tempted to say that he is at liberty to postulate anything that he pleases, and investigate

(*Continued on page 286*)

*WHEN the Einstein essays begin to appear in print, it will be found that many of them will have something to say about the non-Euclidean character of the geometry of the Einstein four-dimensional time-space manifold. This sounds like a very large order but it is not half so bad as it sounds. The competing essays, however, will not be able, in the space allotted, to give this phase of the subject anything like the background which it ought to have. It seems that such background may properly be supplied in advance rather than as an afterthought; so the Einstein Prize Essay Editor has prepared the accompanying material which, with another article in a later issue, aims to make it plain just what the mathematician is getting at when he talks of non-Euclidean geometry. We have asked this member of the staff to try to make good on the boast, which he recently incorporated into a review of Einsteinian literature, that he tries to be a human being. We hope that he has succeeded.*—THE EDITOR.

# Shortening the Route from Farm to Consumer

## One Way to Do This by Reversing History and Extending the Rôle of the Farm

By John T. Bartlett

SOME farmers only crop the land, as in grain farming and orcharding; a greater number both crop the land and raise livestock, utilizing the feed produced; a very small number crop the land, turn the crops into livestock products and then process the livestock products for consumption by the consumer. Are economic conditions such in America at present that there is an opportunity for the farm which is a complete factory, turning out a finished consumer product? This is a debatable, but important question.

Certainly such practice cannot become general in all branches of farming at present, since it would involve the milling of grain, the packing of meats, and the cooking and canning of fruits and vegetables on a scale which only a ridiculous minority of our growers could possibly contemplate. Even so, however, the dairy industry and the associations of fruit growers which have sprung up in various parts of the country show a tendency to undertake just this task on a cooperative scale; and here and there we find cases where the individual farmer is going in for a complete handling of his product. One $300,000 farm enterprise in the Northwest is predicated on a belief that the time is opportune for a type of large farm which performs every step, except retailing, in the production and distribution of such staples as butter, eggs, and all kinds of meats.

This is a property of 2,500 acres, intensively developed for the past ten years. It has a poultry plant which at times has held as many as 4,000 head. The intention is to standardize at 8,000 head. Dairy barn facilities are for 200 head of cows. The hoghouse has a capacity of 2,000 head. These are large-size buildings, as farm structures go, but not especially unusual. The interesting thing is that the farm equipment goes much further. It includes a $35,000 packing house, built in 1911 of tile and concrete and with a complete equipment all the way from slaughter room to storage. There is a creamery which has a capacity of 60,000 pounds a year.

Several score years ago both creameries and packing houses were unknown in the twentieth century sense. Butter was formerly wholly made on farms; now it is made in large or small creameries, some owned by coöperating farmers and others by private interests. Before cream is manufactured into butter nowadays it typically travels anywhere from several miles to two or three hundred from the point of production.

The same thing has happened in meats. Beef, pork and mutton were once slaughtered, cut up and cured on the farm where produced. Then came local slaughter houses and finally the great centralized packing plants of the present day. Farmers still do considerable slaughtering for home or neighborhood use, but practically no other. There was a time when the farm was a complete farm factory, and when its functions were not complete until it had prepared the product for the consumer. The whole trend of the times has been away from this condition.

Now, with the development of a higher level of merchandizing ability among farmers will farm enterprises which go back to the old function—with a difference—become extensive? Do economic conditions provide a place for such farms?

The experience to date of the Washington project is not conclusive. The farm has demonstrated one thing, that in its particular case it is not practical to cut out the retailer, building distribution on the parcels post. The original intention was to do this, and an extensive mail trade was built up, but the plan proved unprofitable. The present arrangement is distribution through the retailer. A retail store in Tacoma specializes in the farm's products; the farm trade-mark is featured, and a lunch counter is made an effective trade-builder. Working along these lines, the management believes its methods are economically sound.

On the other hand, a New England farm near Springfield, Mass., having a smaller output than this one in the Northwest, has established a system of consumer routes. A wagon carries eggs, butter and vegetables in summer and in winter these and such home-made country products as hulled corn, hominy, sausage meat, jellies, pickles. The farm is very careful in selecting a salesman. No ordinary farmhand will do. He must know how to sell, and how to build up good will. He is paid a salary and commission.

Again, one of the largest mixed farms in New Hampshire has for years eliminated all middlemen and marketed direct to the consumer, but here the consumer is a large Boston hotel which owns the farm. Butter, meats, fruits, etc., are produced. It is understood the farm thus operated is profitable. A big chain restaurant with establishments in many eastern cities did the same sort of thing for many years.

In all such methods to shorten the distance between farm and consumer, management is a critical factor. No plan of doing business is "fool-proof." There must be clever, shrewd management behind it to make it a success. The fact that many attempts to market in a new way have failed is indubitably partly attributable to the fact that inexperienced people have launched many such ventures.

### Some More Newspaper Astronomy

To the Editor of the SCIENTIFIC AMERICAN:

I was much interested in the article you had some weeks ago about the misinformation that was published in the Albuquerque paper. I ran across one yesterday in the *Los Angeles Times* that seems to me even worse, and thought you might appreciate it. It occurs in the "Questions Answered" column of this sheet, and is in reply to an inquirer who wants to know why the moon isn't always round. The oracle tells him:

"The moon is always round, but its changes in appearance are due to the earth's shadow being thrown upon it as the earth passes between the sun and the moon. The size of the shadow varies each night that the moon is visible."

It would seem that this explanation leaves something still to account for. So far as I know the earth is always the same size, and therefore it seems rather extraordinary that its shadow should vary in magnitude. Also, why the reservation about the nights when the moon is visible? Are we to suppose that no moon is merely a total eclipse?

Still, we shouldn't be too hard on him. Doubtless the same member of the *Times* staff attends to the astronomical queries and the advice to the lovelorn, and too great accuracy should not be expected of one who adopts such widely divergent specialties.

Los Angeles. A. E. T.

### Protect the Standing Train

To the Editor of the SCIENTIFIC AMERICAN:

I would respectfully ask, in view of this last terrible accident on the New York Central, if it would not be pertinent to again call attention to the absolutely criminal carelessness of leaving the rear of a standing train unprotected, as well by derail as by signal. A train might run by signals, but never by a well-placed derail.

If not in this case, the particulars of which are not at hand, certainly in most cases, there is time to place a derail in addition to the ordinary signals, and seldom would a derailed train work the havoc to itself that it would by crashing into the rear of a standing train. GEO. T. PAINE.

Waterville, Me.

### Pure Water at Low Cost

To the Editor of the SCIENTIFIC AMERICAN:

Inasmuch as the question of pure water is an important one in every household, and as the supply of pure water is not always available, I will briefly outline a simple means of obtaining the purest of water (distilled) at a minimum of cost and with no other appliances than those found in the average kitchen.

I use an aluminum tea-kettle and a quart glass milk bottle. I have the milk bottle tilted so that its bottom is about six inches above the lid of the kettle, the neck of the bottle passing over the spout of same. Very little heat is required to keep the water in the kettle at a boiling point, and the condensation, drop by drop, will amount to a quart, without interfering in any way with other kitchen work.

Inasmuch as the ordinary means of distillation is complicated and expensive, this simple way in which I obtain absolutely pure water is worth passing on.

Rhinelander, Wis. J. C. TEAL.

### The Origin of Coastal Ripple Marks

To the Editor of the SCIENTIFIC AMERICAN:

Permit me to ask the attention of the author of the article on the *Geology of Ripple Marks*, and of your readers, to a theory I have reached during ten years of study of the method of their formation.

It has seemed to me that these markings are usually, if not always, caused by water driven upshore by the ocean waves and the forming of little pools or lakelets in depressions of the sand by the lowering tides. As the tidal ebbing continues the water in the little ponds seeps through the sand, seeking the lowered level of the adjacent water. In doing so the scales of hornblende and quartz are sorted, compacted, and wrinkled by the currents of sinking sea-water into the characteristic contortions and ripples. An admixture of mud in the higher levels results in the larger and more contorted wrinklings.

Atlantic City, N. J. GEO. M. GOULD.

### Life on Mars?

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of March 20th the insistent problem of life on Mars is attacked by a correspondent, C. Fitzhugh Talman, an avatar of Martian habitability. Mr. Talman writes in fine conservative vein as he seeks to "revert to sanity on the subject." He summarily dismisses the possibility of biological evolution on Mars, stating that "nothing we know of the evolutionary process warrants such an assumption."

I deny the validity of this sweeping assertion, and thereon join issue with Mr. Talman.

Nearly every biologist knows that, glowing in the photospheres of distant suns and buried in the soil of alien planets, there exist the same chemical elements that compose the organic creations on this earth—sodium, nitrogen, calcium, carbon, oxygen, et cetera. When a planet cools to the "terraqueous" epoch, as the late lamented Doctor Percival Lowell termed it, these chemicals are brought into play in the planet's life history.

Mammalian structures, increasingly complex and elaborate, originated in the depths of our hot primæval oceans, later to emerge upon the land areas. In even the "least propitious milieu" they found the means of sustenance and growth, and forthwith proceeded the drama of life on our planet.

True, the latitude within which Nature can adapt her creatures is generous, yet Huxley's protoplasmic life-molecule only functions and survives within limits from 32° Fahrenheit to 107.6° Fahrenheit at the upper extreme. Exposure for brief periods to higher temperatures, such as 150°F. and 160°F. in Death Valley is possible, but generally tends to evaporate the water in the tissues and coagulate the albumen in the bodily fluids.

Now, Doctor Lowell demonstrated from Merriam's survey of the San Francisco peaks in Arizona that the maximum summer temperature during the breeding season to which high mammalian orders were exposed—not the rigors of winter cold—determined the possibility of survival. He furthermore showed that the climate of Mars must resemble that of an elevated plateau in a desert region such as Arizona.

Several years previously Arthur Stentzel, analyzing the problem on mathematical grounds, arrived at a mean annual temperature for the poles of Mars of about +12°F.—far higher than its distance from the sun implies. But as summer comes on, the temperature at the Martian equator rises to the mean annual value of 98.1°F. or ten degrees higher than the earth's. This amply included and justified the upper limit determined on less exact data by Doctor Lowell in his work, "Mars as the Abode of Life" a few years previous.

San Francisco, Cal., U.S.A. DONALD P. BEARD.

# Running the Gauntlet of Quality Production

## The Tests That an Automobile and Its Parts Have to Meet Before Passing from the Factory

By Ralph Howard

INDUSTRIAL Europe has long recognized with grudging admiration the cheapness and speed of American standardized quantity production. It has in general felt itself unable to compete with our methods, but has comforted itself with the belief that these methods could never equal the supreme quality of jobs produced by the hand-fitting work of their skilled mechanics.

This was true for a time, but is true no longer. American shops are now turning out work which is both standardized and of supreme quality. There is a considerable number of our factories which can produce goods equal in every way to the best Europe has ever made, and with the added advantages of standardization. American watches are now equal to the Swiss, American machine-made shoes are as good as the English hand product; American machine tools lead the world.

Recognition of this advance in the quality of our production has come very slowly, even at home. Abroad it has barely begun to appear. The reasons for our success are little understood, yet they are simple, and when once known show why our methods not only do produce the highest possible work, but must inevitably do so. They are a skilful combination of science and art, applied rigorously to industrial processes. Perhaps the best illustration of this, because of the wide range of work done, the large number of operations involved and the severe tests to which the product is put, is to be found in the automobile industry.

Under the old system a skilled man achieved accuracy in the assembly by making each part fit the part with which it was to work. The final touches were by hand. The fit could be made exact. Under the modern method there are no final touches to be put on when the parts come to the assembly lines. They have been finished with such accuracy that each will fit into place perfectly without further attention, and fit as well as by any possible skilled adjustment.

There are about 2,300 individual parts put into a big passenger car, ranging all the way from the tiniest screws to the two-hundred-pound cylinder-block castings. The magnitude of the task of having each one of these parts come to the assembly line perfectly fitted to take its place with any other part chosen haphazard from the stock bins can be seen. Yet it is accomplished by a wide and rigid system of inspection under which it is almost impossible that any unfit part can reach the stock rooms. The errors that occur are negligible; they are always corrected by the further inspection of the assembled product that finally takes place.

The extreme degree of accuracy which is insisted upon in the machining of parts is shown by the limits of tolerance which are permitted on inspection. These of course vary widely; it would be merely extravagance to demand hair-line accuracy in a door-latch, or a profile accurate to the thousandth of an inch in the fan. But to say of the machining of the working parts that they were merely accurate to a hair's breadth would be a libel. Many of them are four or five, and some ten times, as accurate as that.

In one car tolerances that come within a thousandth of an inch are too numerous to list. There are 331 of them—and each of these is an accuracy to half the thickness of the finest human hair. Of these 81 are on the rear axle and brakes, 29 on the steering gear, 72 on the clutch, 102 on the motor and 47 on the transmission. But there are nineteen processes which are permitted a tolerance of only half a thousandth; there is one that is held to three ten-thousandths, there are three to .00025 and two to two ten-thousandths of an inch. These tolerances are, for practical purposes, absolute. They cannot be exceeded except in the laboratory, at carefully fixed temperatures, since the heat of the hand will cause a variation of at least a ten-thousandth of an inch in a three-inch standard steel measuring block.

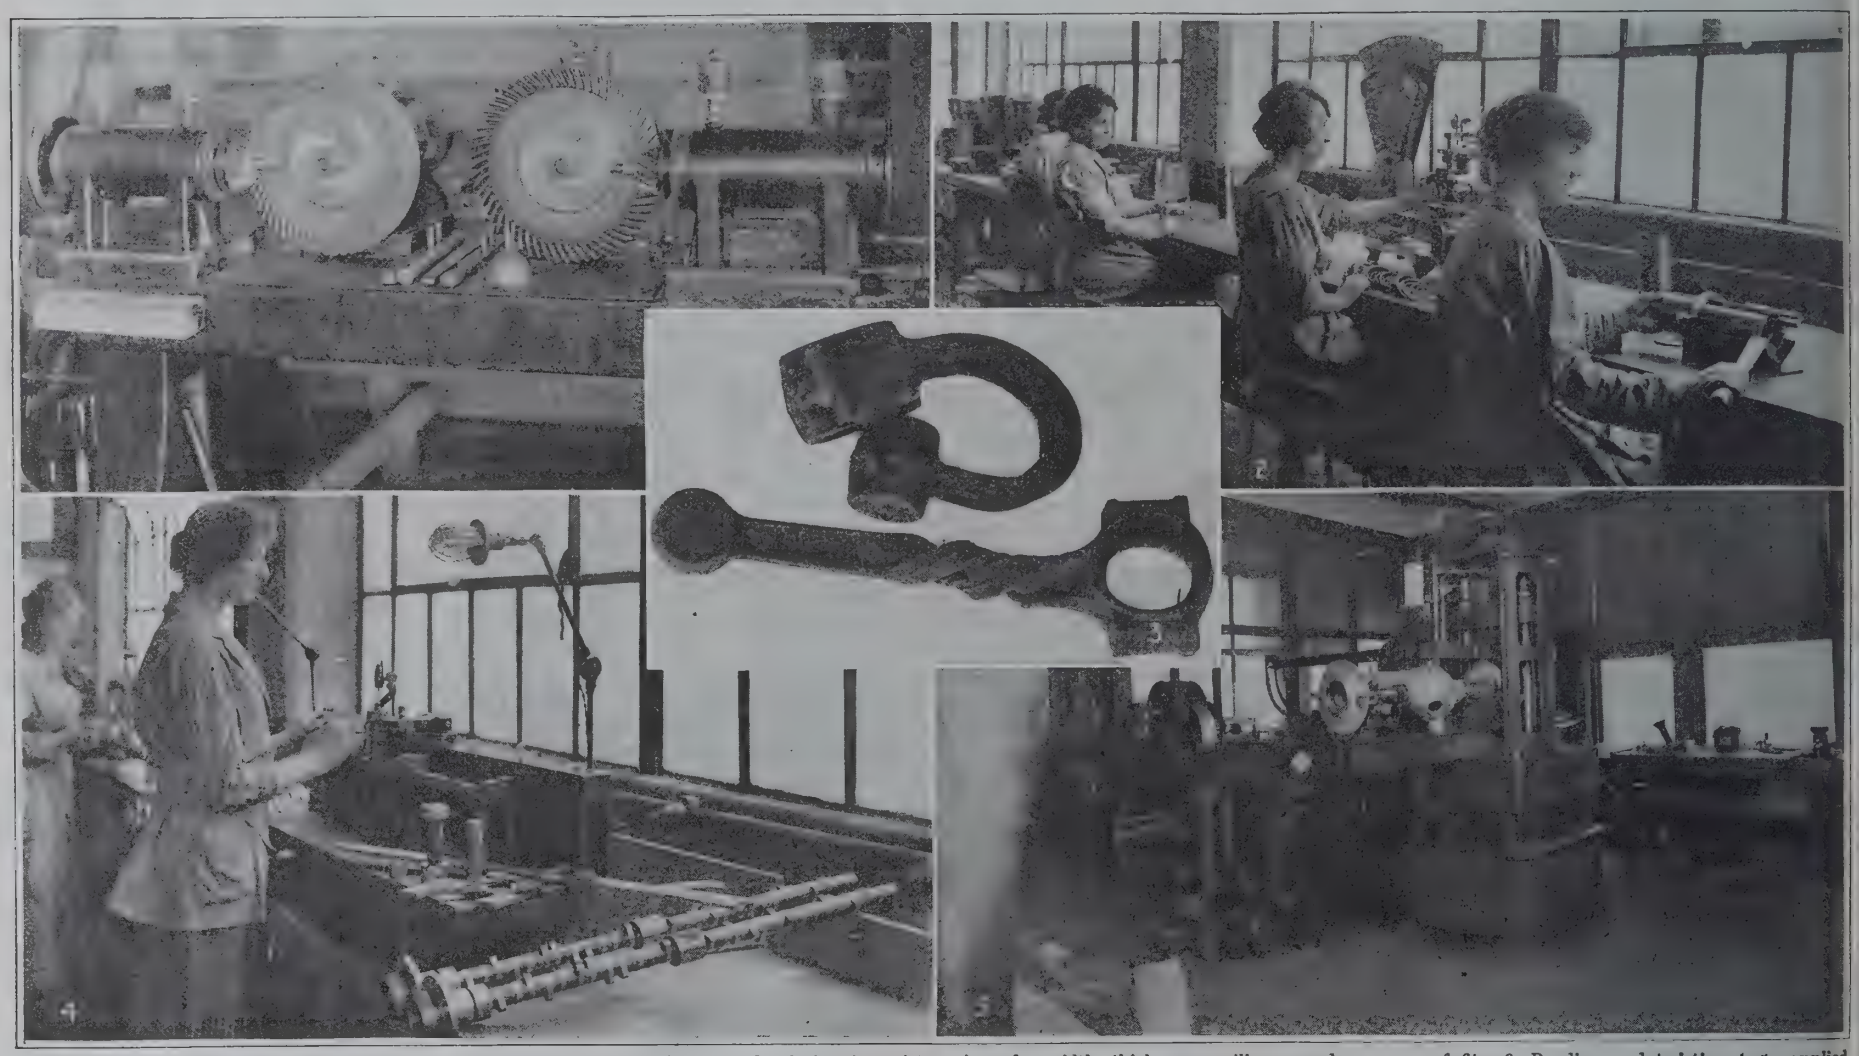
To maintain the inspection which will insure such accuracy is one of the most costly, as it is the most necessary, factors in quality production. Approximately one employe in every twenty is an inspector, and in addition minor executives, like the jobsetters, have definite inspection functions. The mass of gages necessary is staggering. There is a total of some 15,000 in constant use; of these 3,000 are to a thousandth of an inch, and they are kept accurate by constant inspection which brings each one to a testing machine about once every three weeks. It is needless to say that with such accuracy demanded on inspection of parts, there is a most careful inspection also of drills, jigs and bushings, to insure that inaccuracies do not creep in during machining.

All inspection is by blue print specifications, and for many of these inspections special gages and profile forms have to be used. So small a thing as a valve, for instance, is inspected on nine different points. The slot is tested for width and length. The stem is ring-gaged for its entire length. A profile gage is used to test the length and the angle of the face. Both the face and the end of the stem are tested on the scleroscope for hardness. There are 24 such valves to each engine—a total of 216 inspection operations for the engine valves alone.

The steering rod calls for 26 inspections, and a total of 43 inspection operations, since several tests have to be made at different points. There are six tests on each piston ring. Each of the 60 teeth on a transmission gear is tested separately, not to mention the inspection for other points on the gear.

The cam shafts show how complicated the inspection must sometimes become. These are steel shafts, about three feet long, with bearings at either end and a gear at one end, and with two dozen cam wheels. Each of these wheels must be tried in a special gage to insure accuracy of eccentricity and accuracy of placement for timing; each must be tested on both faces for hardness. The tolerance on the machining is one thou-

(*Continued on page 288*)



1. If the gear does not run noiselessly when tested on this motor it is rejected. 2. Testing piston rings for width, thickness, resilience, and accuracy of fit. 3. Bending and twisting tests applied every little while to connecting-rod blanks taken at random from stock. 4. Gaging cam-shafts to insure that they will give accurate timing. 5. Crushing an axle-housing in a machine capable of exerting a pressure of 100 tons

## Coasting With Wheels Instead of Runners

IT appears that coasting is pretty much of an all-year-round sport in Switzerland. Indeed, no sooner does the snow disappear and the warm weather is well under way than the sled is replaced by a small three-wheeled coaster of the general type shown in the accompanying illustration. This vehicle is steered by means of a simple handle controlling the single front wheel. A set of brakes operated by foot controls serves to check the speed during the downward rush over the smooth roads.

**With the advent of warm weather the Swiss tourists abandon the sled and turn to the three-wheeled coaster**

## Raising Two Million Baby Trees

FROM the moment the tiny seeds are placed in beds until the bedraggled "monarch" of the forest yields to the storm and stress of years, trees are not impervious to the undermining depredations of insects and rodents. Mindful of this fact, Uncle Sam establishes safeguards around the seed bed as well as jealously guards the grown-up trees in the National forests.

Acreage devoted to sprouting young trees for transplanting 7,000 acres of land annually is covered with fine screening as a protecting influence against insects and rodents that would uproot the otherwise promising crop. A type of screen recently devised for this purpose is so constructed that the sides as well as the top are detachable, thus permitting of storage in compact space when the screening is not in use.

Seeds selected for perpetuating the National forests are assembled by the U. S. Forest Service the previous fall for planting the following spring. Germination tests are first made to determine the vitality of the seed, after which they are sown in beds at a rate sufficient to yield about 150 trees to the square foot.

Ordinarily, Uncle Sam replenishes his diminishing stock of trees in the National forests at a rate of 1,000 young trees to the acre. Couple this fact with the production of 150 trees to the square foot in the seed bed and you can calculate the mileage of screenings used in safeguarding the plant life from its enemies. The seeds are brought to fruition in large nurseries, the photograph showing a seed bed with a capacity for producing about 2,000,000 plants. The view is of the Savenac Nursery in Lolo National Forest, Montana.

**One hundred and fifty trees to the square foot are raised in these screened-in plots of ground, or a total of two million plants at Montana U. S. Forest Survey nursery**

## Can We Fire-Proof Aerial Mail?

THE witticism of the experienced aviator, "Flying is perfectly safe—that is, unless you happen to fall," is taken literally in a re-fashioned adaptation by the United States Post Office Department in establishing safeguards around the aerial mail service. Disastrous crashes of mail-transporting machines at Baltimore, Cleveland and elsewhere, resulting in the loss of postal pouches from fire, have proved canvas cloth thoroughly immersed in sodium silicate to be ineffectual in protecting the mails. Consequently, the one-piece asbestos container has been adopted for installation in twenty parcel-carrying airplanes. Ten yards of asbestos cloth, with an equal measurement of khaki cloth, of 12-ounce weight, is the composition of the fire-resisting material. The asbestos cloth is of substantial quality, weighing 2¼ pounds to the square yard, and the container is bound together with 1,500 copper rivets. It is made secure in the airplane by thin steel strips and screws having great power. Asbestos buckles and straps are used in fastening the mail in the compartment of the plane. The baggy covering has a capacity for snugly enclosing eight of Uncle Sam's largest No. 2 mail pouches, affording protection for 320 pounds of postal matter. The maximum capacity of mail-carrying planes is 620 pounds. Three different types of asbestos containers are being installed. Twelve DeHaviland planes, six of the new type R-4, and two of the old type R-4 machines are being equipped with containers. The containers are being constructed by the Mail Equipping Shops in Washington.

A series of tests has been conducted by officials of the Post Office Department at its landing field, College Park, Maryland, to determine the reliability of the containers in safeguarding mail from conflagrations. A pouch of dummy letters, enclosed in the asbestos covering, placed in a barrel of shavings which had been soused in a gallon of gasoline, then applying the torch, was the basis of the experiment. After being subjected to intense heat for twenty minutes, the mail was removed. With the exception of the packages of letters on the outer edges of the container being charred, the mail was practically intact.

A spraying apparatus for shooting fire-extinguishing liquid in the mail, gas and engine compartments of the airplane; an automatic ignition interrupter, and the placing of an asbestos bulkhead between the gasoline and other compartments of the plane—these are the fire-resisting precautions designed to increase the efficiency of a mail service that is hazardous at best.

Copyright Harris & Ewing

In burning a pouch of dummy letters enclosed in asbestos for 20 minutes, only the edges of several packages of letters were charred

## Spoilage of Corn

IT is well known that every year thousands of tons of sound corn deteriorates or spoils during storage and transportation. According to one authority, during a period of four months in one year the deterioration of corn arriving in the Chicago market exceeded the value of four million dollars, and the problem of keeping meal in a state suited for human consumption has long been a problem. In view of these circumstances, a study has been undertaken at the Kentucky Agricultural Experiment Station. The conclusions state that excessive moisture is the principal cause of deterioration and spoilage of corn. If the moisture does not exceed twelve per cent, sound grains can be preserved for a considerable time. Such grains will readily absorb moisture if exposed to air in which free moisture exists, and molds, which cause the very rapid deterioration of oil and starch in corn will develop on grains containing fifteen per cent of moisture even at normal temperature if the ventilation is inadequate. If twenty per cent of moisture be present fermentation, producing alcohol and acetic acid, takes place under similar conditions. The danger during exportation is probably due to the failure to dry the corn before placing it in the holds and in not keeping the moisture below twelve per cent during the voyage.

In the case of corn meal, the germ seems to contain an easily oxidizable substance which, when exposed to the atmosphere, produces an acidity, which however will not develop if the corn meal is deprived of its moisture. If the temperature be lowered the development of acidity is retarded. Meal made from degermed grains is inferior to that made from whole grains and the latter, if it does not contain over twelve per cent of moisture, can be kept away from moisture and held in a condition fit for human consumption for some four to six months.

## A Fire Caused by Water

A FIRE which was somewhat unusual in its origin occurred the other day in a dwelling-house in England, says a writer in an English paper. It started in the fusebox containing the fuses for the various lighting circuits in the home. The box was attached to the kitchen wall, and immediately above it ran the two pipes supplying the hot-water system. When the kitchen fire was out, the water in these pipes was, of course, cold, so that they acted as a surface condenser on the kitchen atmosphere, and a steady drip of condensed water took place down the kitchen wall. The pipes were whitewashed, and the condensed water in consequence carried with it a certain amount of calcium carbonate, which destroyed the rubber insulation of the conductors at the point where they passed from the metal tubes in the wall into the fusebox. In turn the copper conductors were corroded with the formation of copper carbonate, and finally the section of wire remaining was so small and its resistance became so great that it got red-hot with the current passing, and set fire to the insulation, spreading ultimately to the woodwork of the fusebox. Fortunately, the failure of the lights gave warning and allowed the fire to be extinguished before any serious damage had been done, but if it occurred in middle of the night, when a light was switched on for a few moments only, the results might have been very different. Of course, no good electrical engineer would place a fusebox or any electrical apparatus on a wall which was liable to dampness, but in these days, when so many people are calling themselves electrical engineers with nothing more to support the claim than an elementary knowledge of wiring, the householder cannot be too careful.

**Sardine fishing and canning plant on Monterey Bay, California**

# From Fish to Food

## How the Toothsome Sardine Is Prepared for the Market by Regular Factory Methods

### By Arthur L. Dahl

BIG industries, as well as big events, grow out of little things. The sardine is probably the smallest fish utilized for food, and yet the canning of this toothsome morsel is developing into a very large industry on the Pacific Coast. We have often heard of a tail wagging the dog, and the sardine industry is a case in point, for its beginning in southern California grew out of the exigencies of another fish-canning industry—that of the tuna. Tuna fish are large, very undependable in habits, and although canned tuna is a strong rival of the salmon, the conditions surrounding the tuna-packing plants were very unstable. There was either a feast or a famine of the big fish, and to stabilize conditions somewhat the packers turned their attention to utilizing some of the small fish caught by the fishing fleet operating in the vicinity. The first sardine canning was done merely as a side issue, to keep down overhead, but its development has been so rapid that now the sardine industry outranks that of salmon fishing in many parts of the West Coast.

The type of sardine packed on the Pacific Coast, is larger than its eastern cousin, or those of European countries, but the meat is fully as good in flavor and texture, and the western sardine is rapidly coming into favor because, the fish being larger, more food can be bought for the same amount of money charged for the smaller fish of the East.

The sardine occurs in great abundance along the entire west coast of the United States and southward on the coast of lower California. It is taken the year round and is especially abundant from September to December. It spawns in the spring. It is an oily, delicately-flavored fish that resembles very closely the European sardine.

The principal sardine fishing-grounds are off the Coronado Islands, in La Jolla Bight, off Redondo, at Santa Monica, Newport and around Santa Catalina Island, in southern California, and in and about Monterey Bay and at Santa Cruz in central California. A number of commercial sardine-packing plants have been established near the fishing grounds, and in these plants the most modern equipment has been installed for cleaning and canning the tiny fish.

Off the coast of Maine, where numerous packing plants are located for the handling of sardines, the fish are caught largely by the use of weirs, but in California this method cannot be used because the coast sheers off into deep water. There are no flats and no places to put weirs, and the only way one can get sardines is to go out with nets. The Japanese and Italians are especially efficient and go out just before daylight, and by the phosphorescent gleam in the water can encircle a school of sardines and bring them in. Sometimes they get so many they cannot land them in the boat. To prevent the fish from being mutilated by piling them too deep in the fishing boats, various regulations have been promulgated by the fishing authorities limiting the height of the fish in boats.

The sardine fisherman ordinarily use a round haul or circle net, about 1,200 feet long, 50 feet deep in the wings and 150 feet deep in the bag. A line of corks are fastened along the upper edge and a lead line along the lower edge. The mesh ranges from ½ inch in the bag to 3 or 4 inches in the wings.

The net is kept in the stern of the boat, and when a school of sardines is sighted one end of the net is let out and the boat circles about until the net is entirely out and the two ends are close together. It is then slowly drawn in by hand until all of the fish are forced into the center of the bag of the net, where it is an easy task to scoop them out with wire scoops.

At first the fisherman would merely dump the fish into the boat to a consid-

1. Filling the cans with the raw sardines; the upper conveyor brings the empty containers to the girls, and the lower belts carry away the filled cans. 2. Where the sardines come from—hoisting a catch from fishing boats to cannery. 3. Clamping on the lids. The boxes are carried on the belts to and through the capping machines, and with hardly a pause on to the cooker.

**Three stages in the process of converting sardines from fish to canned food**

**Left: German "biscuit" porcelain coins, 2, 3 and 5 mark pieces. Right: Siamese porcelain tokens issued by gamblers but prohibited in 1871**

## German Porcelain Money—An Old Idea Revived to Offset Cheap Marks

IT is now proposed to issue coins in Germany of a denomination of 2, 3 and 5 marks of porcelain. The mark has depreciated to such an extent that it would hardly pay to coin it in anything more valuable than copper or iron, and porcelain seems to be an excellent medium of exchange. Municipal coins particularly for use on cars, "tram currency," are now in use in Hamburg and other cities. The factory facilities are large at Meissen and there is nothing specially to make at present so that there seems to be no reason why porcelain coins should not be manufactured at the erstwhile plant that turned out vases and wonderful dinner sets. The coins are very sanitary, as to clean them it is only necessary to throw into water. Owing to the technical plant required for their fabrication—we cannot say minting—they are very difficult to counterfeit. Porcelain coins are not new, as two of the old English potteries adopted "china" or porcelain tokens. They were made at Worcester in denominations of one and two shillings. In 1801, five and seven shilling tokens were issued at Pinxton. These were oval in shape, flat on one side and convex on the other side, which bears the value in large figures. They were called "chang" or "chanu" money, a dialect corruption of the word Chinese.

It is the oriental use of porcelain for coinage which possesses the most interest. Siamese porcelain tokens were in use from the middle of the 18th century until 1871 when they were forbidden. The majority of these pieces were issued in Bangkok, largely by gambling houses, the fraternity at that time having an enviable reputation for honesty! There are at least 890 known kinds. They occur in a great variety of shapes, colors and values. The denominations are on the reverse and are generally in blue. The native name of this currency is "Pi." The inscriptions are usually in Chinese as the gambling houses were usually owned and operated by Chinese.

The origin of the coins or tokens is interesting. Gamblers in Siam squatted down on an oblong mat at one end of which the cashier or *croupier* was seated in a kneeling attitude. The coins which changed ownership so frequently were thrown a considerable distance, and, being bullet-shaped, often rolled in the wrong direction. To remedy this the owners introduced special counters like the well-known "chips" with which the average red-blooded American is entirely familiar. In time porcelain was adopted and the use of the counters was gradually extended to general use as they were issued under authority granted in the gambling license or concession. So they rapidly became a medium of exchange and were found to fill a long-felt want for small money, but the circulation went beyond its legal sphere. Counterfeits soon made their appearance and the gamblers made constant changes in the size, shape and colors for they are found in round, oval, star, lozenge, gourd, leaf, butterfly, bat and fish shapes. Finally the government interposed and would not allow the tokens to circulate as money although they probably still pass muster in the games of "fan-tan" or whatnot which so interest the Celestial. There is a large collection of these tokens in the Museum of the American Numismatic Society in New York. For our photographs we are indebted to our valued English contemporary the *Illustrated London News*.—By *A. A. Hopkins.*

## What Automobile Racing Does to the Delicate Machinery Called Man

WHEN Gaston Chevrolet climbed from his little green racing car after winning the 500-mile International sweep stakes automobile race at Indianapolis recently, after having driven steadily for nearly six hours at the average speed of 88.16 miles per hour, his eyes were almost lifeless. In medical phraseology they were "dead." His face was haggard and drawn. The muscles of his legs and forearms were cramped and knotted. His head drooped and his steps faltered.

In fact he looked like a man who had just taken a dose of poison.

And that is exactly what happened!

The strain of clutching the wheel of his car for more than five hours and forty minutes, never once relaxing his hold or taking his eyes off the dizzy white stretch of brick pavement always ahead of his speeding machine, had caused physical fatigue equivalent to poison, for fatigue is defined as poison by prominent medical authorities. And fatigue poison is just as effective in its action as arsenic or carbolic acid. An overdose of either would be fatal.

The accompanying pictures tell the story of Chevrolet's complete exhaustion. One shows him, fresh, alert, smiling and full of energy, ready for the gruelling 500-mile race. The other shows him, gaunt, and haggard of face, with colorless eye, drooping head, sagging body and cramped muscles, as attendants helped him from his car after the race, and assisted him to his garage. It is hard to believe that the two pictures are of the same man—yet a period of only slightly more than six hours elapsed between their taking.

"The extreme exhaustion suffered by Chevrolet from physical exertion and severe strain of driving 500 miles without a stop at the terrific speed he maintained," declares Dr. Clyde Leeper, a medical expert of Akron, Ohio, "caused certain chemical changes to create poisonous decomposition in the muscles of his body—in other words the production and accumulation of waste substances such as carbon dioxide and lactic acid. In large quantities these are typical fatigue poisons.

"Chevrolet after the race had the 'dead' eye which we found so often among wounded men overseas, among men who had endured long suffering from wounds and exhaustion and men who had become shell-shock victims. Chevrolet's extreme fatigue was equivalent to a severe shock to the complete nervous system—almost the same as if he had been hurled forty or fifty feet in an explosion, and severely stunned. Bicycle riders, marathon runners and long distance swimmers suffer similar fatigue. They all have that 'dead' eye after the acid test of endurance."

Chevrolet's muscles were so cramped his fingers had to be pried loose from the steering wheel. Huge knots in the muscles of his forearms had to be massaged and rubbed down. And chemical action in his body, created by the extreme exertion and strain, caused him to lose several pounds during the race.

Other drivers suffer similar fatigue, many in shorter races. The faster the speed maintained, the more severe the physical strain. For instance, at Beverly Hills when Art Klein drove the 50-mile speed classic at the rate of 111.8 miles per hour, his fingers were clamped to the steering wheel so tightly they had to be pried off. He was powerless to relax the death-like clutch.

# The Romance of Invention—XVII

## The Heart of the Gas-Filled Lamp—Ductile Tungsten and the Man Who Made It

By C. H. Claudy

IT is a conservative estimate to say that the use of the tungsten filament in the modern electric light saves two millions of dollars a day in current.

Behind that saving lies one of the most romantic stories of scientific research which can be imagined. The romance finds its roots in the fact that tungsten is naturally the most intractable of all metals, as for certain purposes it is the most useful. Almost it seems as if Nature defied the scientist and the laboratory to win it for man's use. Not only has it a higher melting point than any other substance (save only carbon), so that it cannot be melted or cast (since anything containing tungsten to be melted would melt before the tungsten), but the metal when produced as such in any other form than a fine powder exhibits characteristics of hardness and brittleness which defy the hammer, the lathe and the die.

Yet today we possess ductile tungsten. We make fine drawn wires of it; we make little disks of it which serve as contact points in our automobile ignition system; our modern X-ray tubes depend upon it.

Given a few ounces of finely powdered metallic tungsten, which cannot be melted in anything because "anything" will melt at a lower temperature than tungsten, how shall one make of it a solid metallic rod? Given a solid metallic rod of tungsten which will break if dropped upon the floor like so much glass, how shall one shape it, work it, draw it into wire?

That was the problem which Dr. W. D. Coolidge undertook to solve with the help of the great electrical laboratories at Schenectady and the resources of men, money and facilities freely provided for the search, because of the enormous commercial importance of the production of tungsten filaments for electric lamps, *which would not break.*

It would take pages, where here are available but paragraphs, to describe the long series of experiments which led to the final success, or more than to indicate the discouragements. The worst of the matter was that there was no knowledge in the beginning that search was not being conducted for something which didn't exist—every shred of evidence available seemed to point to the fact that tungsten was not naturally and never could be made ductile, that the hunt was a hunt for the non-existent.

But Dr. Coolidge had persistency and faith, with a firm belief that if there were no direct way there might be an indirect way; and through indirect ways he worked until he produced the finished article—ductile tungsten, now available, in wire and in rod, in block and in sheet for the purpose which only a metal of such a high melting point (3,000 degrees Centigrade) can serve.

The metal, in the form of a powder, produced by treating the oxide (obtained by chemical means from the tungstate of iron and manganese or from the tungstate of calcium, both of which occur in nature) with heat and hydrogen, is pressed in a mold to form a slender square rod. In this condition it can no more be picked up than can a slender square rod of wet sand. But like wet sand, it can be slid upon a slab, and if that slab be of molybdenum (a metal of the same family as tungsten and with a high melting point of its own) the whole can be inserted into an electric furnace and in an atmosphere of hydrogen raised to a white heat. Kept at this temperature for a sufficient length of time, the individual grains of the metal, while they do not melt, do draw together and become a semi-sintered body. Whether they weld or adhere each to each by surfaces only, makes no difference. The rod, slightly shrunk, can now be handled, though it is yet more brittle than glass and can no more be drawn or hammered than a stone.

The next process is to grip its ends in copper jaws, one pair a fixture at the top of a hydrogen container, the other floating in mercury at the bottom. Through the rod is now passed a current of electricity which heats it again, this time to a temperature just short of the melting point of the metal. The copper jaws at the upper end and the mercury at the lower are water-cooled to keep them from melting, but the rod between is white hot with a heat beyond any otherwise applied to any metal.

*THE story of Dr. Coolidge adds a new angle to the Romance of Invention—the romance of a man who is hired by a great corporation for the single purpose of inventing things, and who proceeds with marvelous facility to invent things that might well have seemed impossible. Indeed Dr. Coolidge himself emphasizes the fact that the great success which he has had in his work with tungsten and its applications is to be attributed not alone to any genius and persistence which it may be his good fortune to possess, but equally to the fact that he is backed by the resources of one of the greatest commercial organizations in the world. And certain it is that many an invention which has not been brought to perfection would have flourished and borne fruit had the prospective inventor been assured of a comfortable salary, competent assistance in every collateral issue, and unlimited financing of such steps in his work as might be beyond the means of a private investigator. The story of tungsten tells us that among all the things that are intrinsically possible, there is nothing that syndicated invention may not hope to conquer.*—THE EDITOR.

When the rod comes from this treatment it has shortened materially. Its particles have shrunk together, coalesced—it has become a solid piece of metal. And now if the original powder was neither too coarse nor too fine and the heat treatment has been just right, the rod will permit itself to be hammered—a little—at a high temperature. This hammering must be very delicately done—a blow too hard and the white hot rod breaks, never thereafter to be satisfactorily welded by any process known to man. In practice the "hammering" is called "swaging" and consists of repeated blows of pairs of successive dies, each pair slightly smaller than its predecessor. A special swaging machine was devised expressly for this work, which regulates the blow to the exact weight necessary, and gives new shape to the rod by gradual steps.

Smaller and smaller gets the rod, and with each hammering, each heating and each decrease in size, it gets more and more tractable, until, when reduced to the size of the lead in a pencil it is in a condition where at last it may be drawn, hot, through diamond dies, and come out the other side in the form of a fine wire, strong as steel and almost as flexible as copper.

There were tungsten filaments before ductile tungsten—processes of mixing the powder with an amalgam or some other binder and distilling out this binder from wire formed from the mixture, resulted in true tungsten wire, but wire which broke with a jar and shattered with a blow. Electric lamps made of such wire were resistive to the heat developed but could no more be applied; for instance, to automobile headlights than glass could be used to make baseball bats. Not until tungsten was made ductile, not until the investigation and research under Dr. Coolidge demonstrated that what the life history of the tungsten group of metals seemed to say did not exist wanted only enthusiasm, determination and time for its complete discovery, did the modern tungsten-filament lamp become a possibility.

The American Academy of Arts and Sciences gave Dr. Coolidge the Rumford Medal for his work in producing ductile tungsten. Not one man in a million, perhaps, who reads by a tungsten light, who sees an electric sign or runs an automobile having an ignition system dependent for its operation on a little pair of tungsten contact points, or who has an X-ray picture made of what ails him with a tube that is efficient and powerful because it has a tungsten target at one end and a hot tungsten cathode at the other, knows the name of the young man with the happy smile and the enthusiastic devotion to this work which has so greatly benefited the world. The scientific world knows, however, and the SCIENTIFIC AMERICAN section of the great American public is now told—Coolidge is the man who did it.

The search for ductile tungsten was conducted with the idea that it was the solution of the great industrial problem—the production of economical and efficient electric lights, possessing long life and ability to keep their candlepower well up during long use. But many other uses have been found for ductile tungsten, of which by no means the least important is its employment as the "target" or anode in an X-ray tube.

The X-ray tube is so much a special tool, confined almost exclusively to the physicians and the sick room, that those without broken bones or foreign bodies intruded into their living machines, or who fail to provide work for doctors by getting pneumonia or cancer or some other diseases which may be either investigated or treated with the strange light rays which pierce ordinary tissues almost as easily as sunlight does glass, know little about it. In the light of Dr. Coolidge's work with the tube, it may even be said that the scientific world didn't know much about it until he took hold of it and developed the hot cathode tube.

Prior to that time, a certain minimum amount of gas in the tube was essential to carry the current across the gap between anode and cathode. In the Coolidge tube the cathode is formed of a tiny spiral of tungsten wire which is heated by a current of electricity. When sufficiently hot, it emits electrons which carry the current impressed upon the terminals across the gasless gap between. Exhaustion of gas in the Coolidge tube is carried to as high a point as modern vacuum production can attain, with the result that puncturing troubles disappear, the focal spot no longer moves, and local heating of the glass is conspicuous by its absence. Moreover the intensity of the X-rays produced is easily and directly controlled by the amount of heating permitted in the hot cathode. High or low penetration may be obtained at will from the same tube, and, equally as important, one operator may exactly duplicate the conditions under

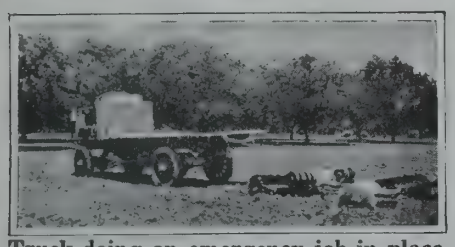
# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*



**Truck doing an emergency job in place of a disabled tractor**

## Motor Truck as Tractor

THE motor truck is constantly proving its versatility and adaptability to all kinds of work on the farm. Not only is its usefulness increasing for delivery work on and about the farm but it has also demonstrated that it can work in uncultivated fields in case of an emergency. This is the discovery of William Berkenstock of Fullerton, California, who used a three-ton, four-wheel-drive truck to disk and sub-soil a ten-acre orchard, in which he was preparing to plant young citrus trees. When his tractor broke down and he was confronted with the task of disking the field before the trees arrived he hooked the disk on to the truck and dragged the entire tract with ease. While this is unusual work for a truck it demonstrates, nevertheless, its versatility and power in emergency cases and also brought out the tractive power of the four-wheel-drive principle in an unmistakable manner.

## Delivering Coal for $1 Per Ton

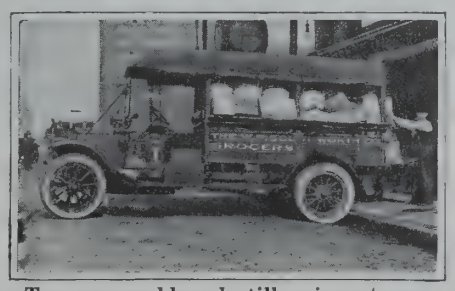
THE big advantage of a motor truck in the coal business is that it brings the outlying sections of the city closer to the coal yards. A prominent firm of retail coal dealers of Brooklyn, New York, use a truck for delivering coal to residences, factories, stores and office buildings, most deliveries being to retail trade. This delivery has heretofore been considered most economical by teams, however, including all items of expense, the motor truck has been delivering coal for $1.00 a ton.

The motor truck actually covers twice the radius of a team, and does the total work of 2½ teams. For instance, during one month recently, this machine made 91 trips, traveled 684 miles, and delivered 526½ tons of coal. In the same month the teams averaged but 325 tons. This average shows that the motor truck delivered 61 2/3 per cent more coal in spite of the fact that this tonnage was hauled twice as far as the horses traveled.

These motor trucks are loaded from overhead hoppers, and a 6-ton machine can be filled in seven minutes. Every morning the motor trucks are weighed to give the actual empty weight each day to subtract from loaded weight. This empty weight varies from time to time and the variation must be taken account of in order to give customers exact weight. The accompanying illustrations show how trucks can be used advantageously in coal hauling. One shows the hopper loading system that cuts down delivery costs, the other shows light trucks hauling lump coal.

## Veteran Truck in Grocery Service

A PROMINENT truck company frequently has said in its advertising that the useful life of its product has not yet been determined and this statement seems to be borne out by the performance of Truck "A," dean of the delivery fleet of a Cleveland house, which has entered upon its tenth year of daily service and bids fair to emulate the example of Mr. Tennyson's well-known brook and run on forever. While not the oldest truck of its make



**Ten years old and still going strong**

in operation today, a number of trucks antedating it in delivery, Truck "A" is unquestionably the veteran to remain continuously in the service of its original owner. It was in May, 1910, that this two-ton truck was delivered to the purchasers by the maker and immediately put into commission in charge of a driver who was a lover of fine machinery and at once made the truck his pride. So carefully did he care for the truck and so carefully was it driven, that in a little more than nine years but one slight mishap marred the record of truck and driver, though all of the work was performed in the midst of constantly increasing traffic perils in the growing city of Cleveland—a wonderful record which, unfortunately was ended by the death of the veteran driver a few weeks ago.

Originally the truck was used to transport goods between the company's three stores in Cleveland, in general hauling from the depots, and in delivery service. When it was four and a half years of age, the owners estimated from the records kept that the truck had then covered 200,000 miles. Since that time a portion of the burden once borne by Truck "A" has been transferred to heavier trucks which have been added to the fleet, but it has easily added an additional 100,000 miles to its record and is today, according to the superintendent of delivery for the company, "in good shape and doing about forty-five miles per day."

This bears out the contention that has been made from time to time in these columns by the writer that more trucks are worn out by abuse than by use.

## Horses Displaced by Tractors

THE number of horses displaced by tractors in the corn belt is largely determined by the number it is necessary to keep for corn cultivation and other work current at the same time which the tractor cannot do. This is perhaps the most important of the facts brought out by an investigation recently made by the United States Department of Agriculture in seven corn belt states, relative to the influence of tractors on the use of horses, the results of which have been published in Farmers' Bulletin 1093.

The Department has drawn on the experience of 191 tractor owners in the preparation of this bulletin, which is designed to enable the corn belt farmer to answer for himself the following questions:

For what operations can I use the tractor?

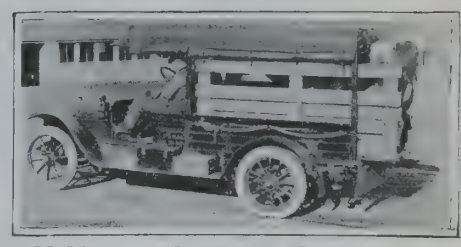
In what operations will it displace horses in whole or in part?

How many horses will it displace on my farm?

It was found that the number of horses disposed of by the farmers in question after buying tractors was between two and three a farm. The average number of acres tillable by horses was increased 12 and the average size of the farms by a total of 22 acres. Several operators displaced horses entirely on plowing, disking and harrowing. Few operators allowed their horses to stand idle while the tractor was in use.

The tractors were used for an average of 29 10-hour days a year on the home farms, no records being taken of custom work. A three-plow tractor on these farms does the work of 8½ horses in plowing, disking, harrowing and harvesting.

The results of this study further substantiate the conclusion that the principal advantage of a tractor lies in its ability to do heavy work in a shorter time than is possible with horses.



**Making good use of the truck in handling live stock**

## Small Packers Aided by Trucks

IT is due to the successful operation of the motor truck as a live stock carrier that small packing centers are being established in different parts of the country. Packing centers shorten the haul to market as the products do not have to be hauled to distributing centers before being sent out to the ultimate market. This in turn has an important bearing on keeping the cost of meat down to a minimum. The live-stock grower instead of loading stock in cattle cars to ship to the different centers now hauls it to the nearest packing center in his motor truck, saving time and expense as well as delivering cattle and hogs in the same condition they left the farm. The consumer in the vicinities of these packing centers is able to get fresh meat at a price lower than if the meat had come a great distance. Thus it can be seen that the benefits of the motor truck are not just those that are directly attributed to it, but are benefits that redound in a greater area than is realized.

The accompanying illustration depicts one practical method of transporting live stock by small motor truck. The animal is carried in a special rack or crate that fits inside the main body and which can be loaded or removed without disturbing the live stock the truck is to carry. This simplifies handling the animals, especially when small and active, as sheep or swine are, and also protects the truck body from the filth inevitable in transporting live animals for any distance.

## Motor Trucks Help Small Towns

MANY a small town which for years has appeared to be doomed to oblivion because it was not lucky enough to get on a railroad line is being put on the map today, and the motor truck gets the credit. This new mode of transportation opens up markets both ways, making it possible for residents of these communities to ship their products at low cost to neighboring cities, and also brings to them the goods of the outside world, thus permitting a growth in population that would otherwise be impossible, especially in newly developed oil and mining districts.

***Left:*** **Rapid and economical delivery of the coal to the truck from the railroad.** ***Right:*** **The largest sizes of coal are economically handled by big trucks.**

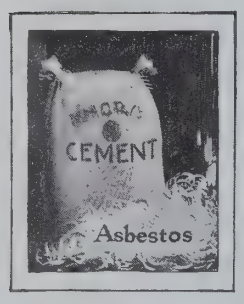
# Shingles of Asbestos beautiful, fireproof and economical



*Asbestos Shingles should not be confused with asphalt or other so-called composition shingles manufactured to meet the demand for low-priced roofing material in the face of rising costs. Asbestos shingles have earned from the Fire Underwriters' Laboratories the high rating of Class A.*

TWO considerations seem to be the basis of everyone's choice of a home roofing material—appearance and durability. And both are important.

Charm in a home roof is as necessary in its way as dependability and durability, for many good-to-look-at roofings fall far short of what might be called a perfect housetop specification. Tile, for instance, is heavy and costly; slate, if not expensive, is heavy and has certain limitations in color and weathering properties.

Even the wood shingle (the traditional house roof of America) is now challenged by the beauty of Johns-Manville Asbestos Shingles which are fireproof, and hence satisfy fully the fire authorites of the more than 114 cities that have prohibited the use of inflammable roofs.

Here, then, in asbestos shingles, we find the one roofing material that combines *all* the qualities that a perfect roofing should have.

Permanently durable and fireproof because they are actually made of rock (asbestos mineral fibre and Portland Cement) nothing organic in their composition to rot, warp or disintegrate under varied weather conditions.

Supremely artistic in their appearance, with all the soft tone values and weathering properties so lacking in other mineral roofs.

No wonder that both architects and house owners are pressing our factories to utmost capacity.

Johns-Manville Asbestos Shingles are easily laid in either the American or Hexagonal method of arrangement and in gray, brown, red or in the beautiful Colorblende assortment—the aristocrat of all roof coverings

*Throw a Johns-Manville Asbestos Shingle into a red-hot furnace. It will not burn.*

## Shall the Corn Field Run Our Cars?

*(Continued from page 274)*

In Germany nearly 70 per cent of the annual output of more than 100,000,000 gallons of alcohol is got from potatoes. In France, on the other hand, the chief source of industrial alcohol has been the molasses from the beet sugar refineries. Both of these basic raw materials are to be had in the United States in abundance, especially potatoes of the kind known to the farmer as seconds and culls, for which there is only a limited market. Potatoes that are unfit for food, because diseased or touched by frost, can be utilized in the manufacture of alcohol. A ton of the tubers, if they contain 16 per cent of starch, will yield 25 gallons of alcohol. Many millions of tons of potatoes are sacrificed yearly which could thus be profitably consumed in the distillation of motive spirits.

But probably the most promising native source of industrial alcohol is our vast corn belt; maize for years has stood pre-eminently as the cheapest raw stuff for the distillers. It is easy to raise, and stands transportation and storage admirably. It is undeniably true that wood waste is susceptible of furnishing a great volume of industrial alcohol, but there are difficulties of an outstanding nature which now seriously hamper putting any of the processes in service upon a commercial scale of moment. Similarly, recent developments in the field of chemistry have shown that it is entirely practicable to get a goodly measure of alcohol from the waste liquor of the mills engaged in the making of sulfite paper stock. The Germans are said to obtain quite 3,000,000 gallons of spirits from this origin annually; and the Swedes are employing a kindred method at thirteen of their sulfite mills—10,500,000 gallons of 100-per-cent-pure alcohol are thus realized in the course of a twelvemonth.

But alcohol in quantity enough for industrial and motive purposes is not to be had from by-product materials. We shall have to count upon an ample primary substance which can be cultivated for that purpose season after season. Here is where corn meets every requirement. It can be planted and harvested within ninety days throughout an enormous area; and a ton of the grain should yield about 89¼ gallons of pure alcohol. A large distillery should be able to handle 10,000 bushels of corn a day, and do this 300 days a year. That is to say, a plant of this size would have an annual output of 7,500,000 gallons.

In 1919 we grew 2,900,000,000 bushels of corn, representing a possible source of 7,250,000,000 gallons of alcohol. As a matter of fact, during the past year, our gasoline consumption amounted substantially to 3,100,000,000 gallons. Manifestly, then, if one-fourth of our corn had gone to the distillers of industrial alcohol we should have been in a position to get enough motive spirits to cut down the use of gasoline by fully 58.4 per cent. And if alcohol were used as the basis of a synthetic fuel such as those already mentioned, the mixture with ether, toluol, and benzol would effect a gasoline economy of quite 70 per cent in one case and 100 per cent that with ether alone.

The point to be kept in mind is that our farmers have it within their power tremendously to amplify the acreage planted in corn; and it has been suggested by the agricultural authorities that it would be possible to secure a still greater yield of alcohol if cornstalks were utilized. But this theoretical source of more motor spirits need not be considered because there are practical difficulties that stand in the way of putting laboratory revelations along this line to commercial use. Success in the manufacture of industrial alcohol rests fundamentally upon a sufficient and a continuous supply of the primary raw material, and, because of its keeping qualities, corn can be harvested and then held in storage where it can be drawn upon months thereafter. In this respect it is unlike a number of other potential vegetable sources of alcohol which can be turned to account for this purpose only during a comparatively short season.

Without going into the details of the making of alcohol from farm products, it will suffice to say that the first object is to convert the starchy content of potatoes, corn, etc., into sugar through the agency of fermentation; and as a further result of the action of the yeast the sugar is split up into alcohol and carbonic acid gas. Subsequent continued distillation separates the alcohol from the water with which it is combined, adding step by step to the strength or purity of the spirits.

According to present practice, little if any of the carbonic acid gas is saved from the fermenting mash, and right here exists a means of greatly lessening the cost of alcohol. A bushel of grain during treatment will give off seven pounds of $CO_2$. This gas has a ready market in the charging of bottled waters, beverages, etc., and for use at soda fountains. In fact, the present demand is far in excess of the supply. The $CO_2$ liberated during fermentation is in its purest state and is superior to that made from marble dust, which has to be very carefully filtered, etc., to render it salable. Carbonic acid gas figures in refrigerating systems, and its fields of application are wide and varied. With a proper installation there is apparently no reason why this money-making by-product of the distilleries should not be conserved.

Lest there be a mistaken notion that a foodstuff as such is lost in the manufacture of alcohol from corn, it should be kept in mind that there is a fibrous residue or "slop" which contains 12 per cent of fatty matter and 33 per cent of protein. This, when dried in drums, looks not unlike middlings, and constitutes an excellent feed for hogs, cattle and chickens. The thin slop may, however, be fed to livestock by mixing it with roughage or by adding a proportion of the "middlings." This brings us to the story of a new fuel, which is rapidly growing in favor and finding many serviceable applications.

## Putting the Payroll on an Automatic Basis

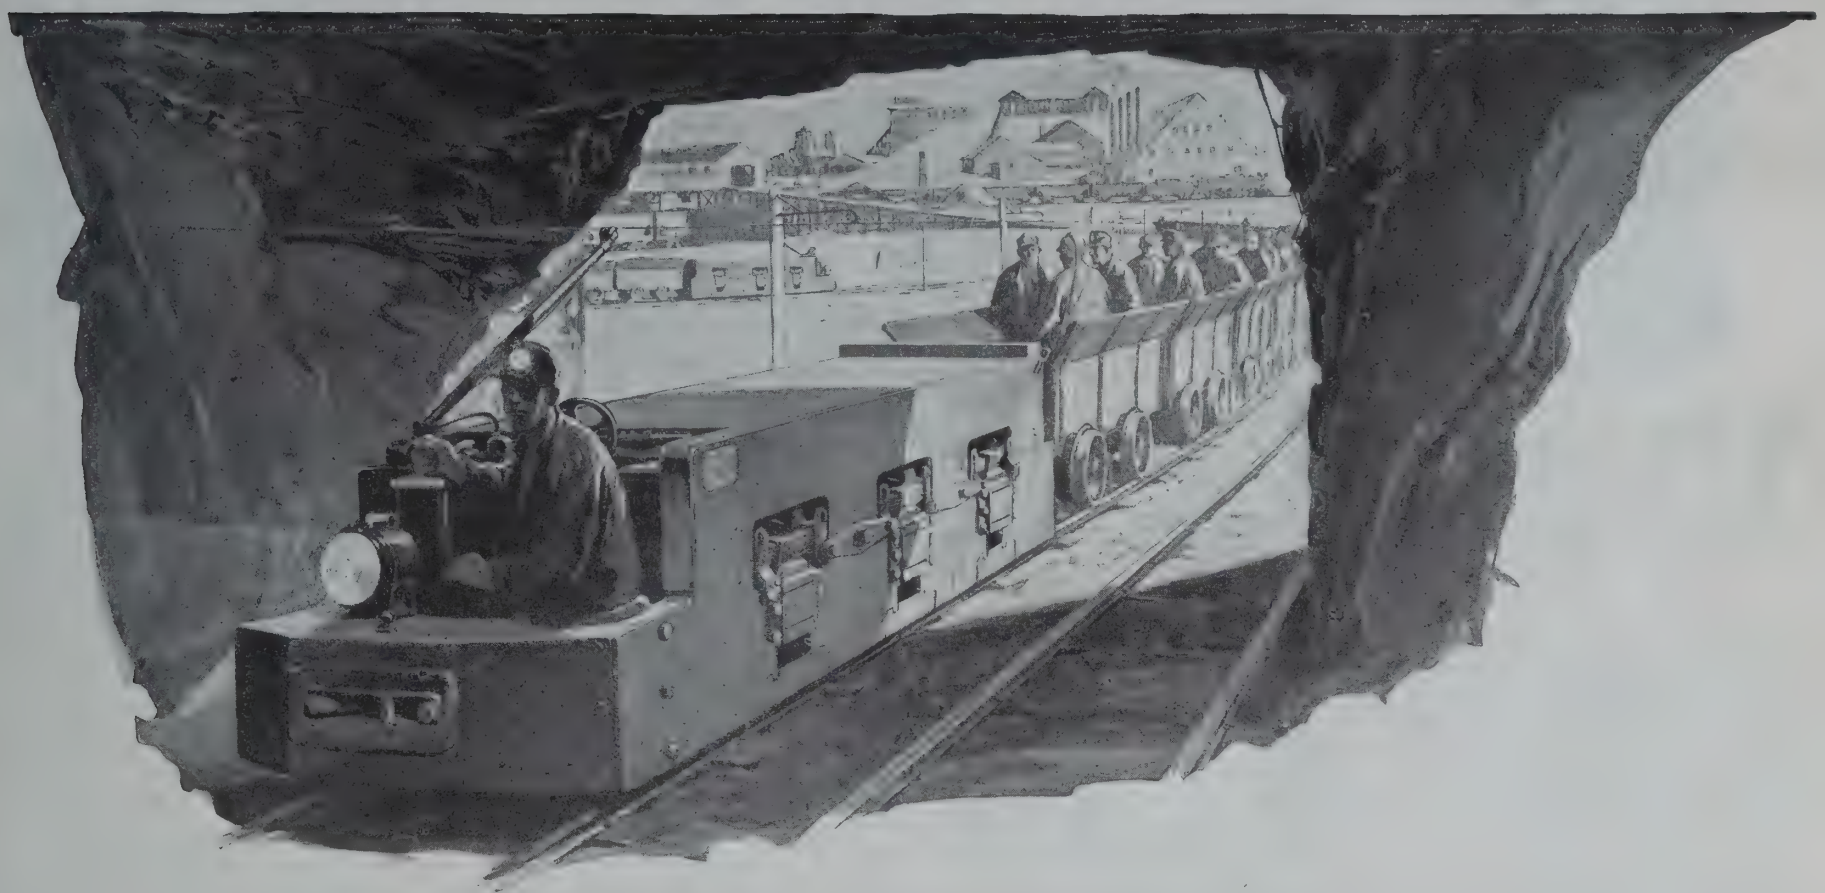
*(Continued from page 275)*

printed record of the amount put into each envelope. In using paper money instead of gold coin the procedure is slightly different but the results are identical. The payroll is thereby apportioned in a fraction of the time otherwise necessary and there is a printed record of the total amount put into each envelope. This record is perhaps the most important individual feature of the machine.

Under the old system, if an employe claimed that his pay was short it was practically impossible to check his claim once he had opened his envelope. Even though the cash had balanced after making out the payroll it was possible that some other employe might have been overpaid a similar amount. With the International payroll machine all such claims can be readily adjusted because the paymaster knows from his printed record exactly how much was put in each envelope. Even if the operator should make a double error, it will appear in the printed record. The machine thereby protects the employe against possible clerical errors and at the same time protects the employer against the claims of dishonest, careless, or mistaken employes.

When not required for payroll work, the machine can be used for adding and other computation in the same way as other visible adding and listing machines are used. This in no way interferes with the payroll mechanism which is connected or disconnected at the pressure of a key.

*In the basic industries of this country, without which other industries could not exist, electricity is the dominant factor in rapid and economical development*



# The "Black Diamond" Miner's Best Helper

WHEN a coal miner clamps on his electric headlight, jumps aboard an "empty" and rolls smoothly along the "motor road" into the mine, his electric day has only begun.

Down in the mine, an electric spark ignites the blasting charge which tears away rock and opens the vein—an electric drill helps him cut his coal. While he works, electric light brightens all operation — electric pumps draw flood water from his path—electric fans supply him with fresh air, increasing his efficiency and protecting him from dangerous smoke and gases.

Small electric locomotives pull cars of coal to the main thoroughfares of the mine, where they are made up into heavier trains and hauled to the tipple by more powerful electric locomotives. There a huge electric hoist lifts cars bodily and dumps the coal into the breaker to be crushed and screened into various sizes by electric motor-driven machines—and later dropped into railroad car or ship by the same operator throwing another switch on the electric control panel.

These manifold phases—necessary to the successful electrification of the mining industry — were broadly encompassed by the accumulated resources and engineering initiative of the General Electric Company.

Such service and facilities are at the disposal of all industry.

# After 10 Days

## See what this new way does for teeth

*All statements approved by authorities*

There is a new way of teeth cleaning which millions now employ. Leading dentists everywhere advise it.

You can see the results wherever you look—teeth that glisten as they never did before.

This is to offer a ten-day test. Then to urge that you let your mirror show how much it means to you and yours.

### Fights the film

The object is to fight the film which causes most tooth troubles.

That viscous film you feel on teeth is their great enemy. It clings to teeth, enters crevices and stays. Then it dims the teeth, and night and day it may do ceaseless damage.

---

It is the film-coat that discolors, not the teeth. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.

Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea. Very few people escape these troubles which are caused by film.

### What ruins teeth

Much of this film remains on teeth under ordinary brushing methods. Many tooth pastes even favor the film. Thus millions find that well-brushed teeth discolor and decay.

The reason lies in film, and dental science has for years been seeking a way to combat it.

The way has now been found. It has been proved by decisive clinical and laboratory tests. Its efficiency is beyond question. And this method has brought to millions a new era in teeth cleaning.

The methods are all embodied in a dentifrice called Pepsodent—a dainty tooth paste which complies with every modern requirement. That is the product we ask you to test in your home.

### Acts in numerous ways

One ingredient of Pepsodent is pepsin. Another multiplies the starch digestant in the saliva to digest starch deposits that cling.

Another result is to multiply the alkalinity of the saliva to neutralize mouth acids, the cause of decay.

Two factors directly attack the film. One of them keeps the teeth so highly polished that film cannot easily cling.

Thus in several ways, new and efficient, Pepsodent combats the teeth's great enemies. It brings essential results which Nature intended, and which old methods failed to accomplish.

### The way to know

Ask for a 10-Day Tube. Watch the results, then read the reasons for them in the book we send.

Those whiter, cleaner teeth you see mean safer teeth. They mean that film, great tooth wrecker, is being day by day combated.

Compare the results with old methods. Then judge how much this new way means to you and yours. Cut out the coupon now.

**Send this coupon for a 10-day tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how the teeth whiten as the film coat disappears. It will be a revelation.**

## New Concepts of the Past Century

*(Continued from page 276)*

the results; and that whether or not his postulate ever be realized, the propositions that he deduces from it, being true, are of scientific interest. Actually, however, it is not quite as simple as all that. If it were sufficient to make a single postulate it *would* be as simple as all that; but it turns out that this is not sufficient any more than it is sufficient to have a single undefined term. We must have several postulates; and they must be such, as a whole, that a geometry flows out of them. The requirements are three.

In the first place, the system of postulates must be "categorical" or complete—there must be enough of them, and they must cover enough ground, for the support of a complete system of geometry. In practice the test for this is direct. If we got to a point in the building up of a geometry where we could not prove whether a certain thing was one way always, or always the other way, or sometimes one way and sometimes the other, we should conclude that we needed an additional postulate covering this ground directly or indirectly. And we should make that postulate—because it is precisely the things that we can't prove which, in practical work, we agree to assume.

In the second place, the system of postulates must be consistent—no one or more of them may lead, individually or collectively, to consequences that contradict the results of any other or others. If in the course of building up a geometry we find we have proved two propositions that deny one another, we search out the implied contradiction in our postulates and remedy it.

Finally, the postulates ought to be independent. It should not be possible to prove any one of them as a consequence of the others. If this property fails, the geometry does not fail with it; but it is seriously disfigured by the superfluity of assumptions, and one of them should be eliminated. If we are to assume *anything* unnecessarily, we may as well assume the whole geometry and be done with it.

The geometer's business then is to draw up a set of postulates. This he may do on any basis whatever. They may be suggested to him by the behavior of points, lines and planes, or by some other concrete phenomena; they may with equal propriety be the product of an inventive imagination. On proceeding to deduce their consequences, he will discover and remedy any lack of categoricity or consistence or independence which his original system of postulates may have lacked. In the end he will have so large a body of propositions without contradiction or failure that he will conclude the propriety of his postulates to have been established, and the geometry based on them to be a valid one.

### And What Is It All About?

Is this geometry ever realized? Strictly it is not the geometer's business to ask or answer this question. But research develops two viewpoints. There is always the man who indulges in the pursuit of facts for their sake alone, and equally the man who wants to see his new facts lead to something else. One great mathematician is quoted as enunciating a new theory of surpassing mathematical beauty with the climacteric remark "And, thank God, no one will ever be able to find any use for it!" An equally distinguished contemporary, on being interrogated concerning possible applications for one of his most abstruse theorems, replied that he knew no present use for it; but that long experience had made him confident that the mathematician would never develop any tool, however remote from immediate utility, for which the delvers in other fields would not presently find some use.

If we wish, however, we may inquire

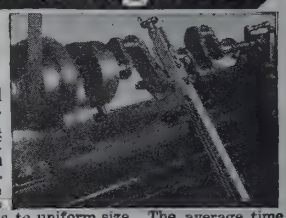
## Weber Crank-Pin Re-Turning Tool

**No Filing**
**No Offsetting**
**No Jigs**



This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

## Understanding

A BOY is learning to shoot an arrow from his bow. His father stands behind him, reaching down to steady the bow and with his own hand clasping the boy's fingers on the string. He draws the arrow to its head and releases it.

The boy acquires an understanding of the method, the *how* of this simple art. Their positions, one standing over and the other "standing under" illustrates why "understanding" is practical, *usable* knowledge. It is best gained in a practical lesson, standing and learning *under* a man who knows the *how*.

This process of teaching and learning has gone on decade after decade in the Grinnell Organization. Newer and better practices in designing and installing industrial piping equipments have been *understandingly* taken up by superintendents and foremen and passed down, in turn, by them to assistants and workmen.

That is how Grinnell Company for 70 years has been constantly making a part of itself all that is best in industrial piping practice. Such experience we believe is today embodied in our nation-wide organization for purchasing and testing materials and planning, fabricating and erecting them into industrial piping equipments of every sort.

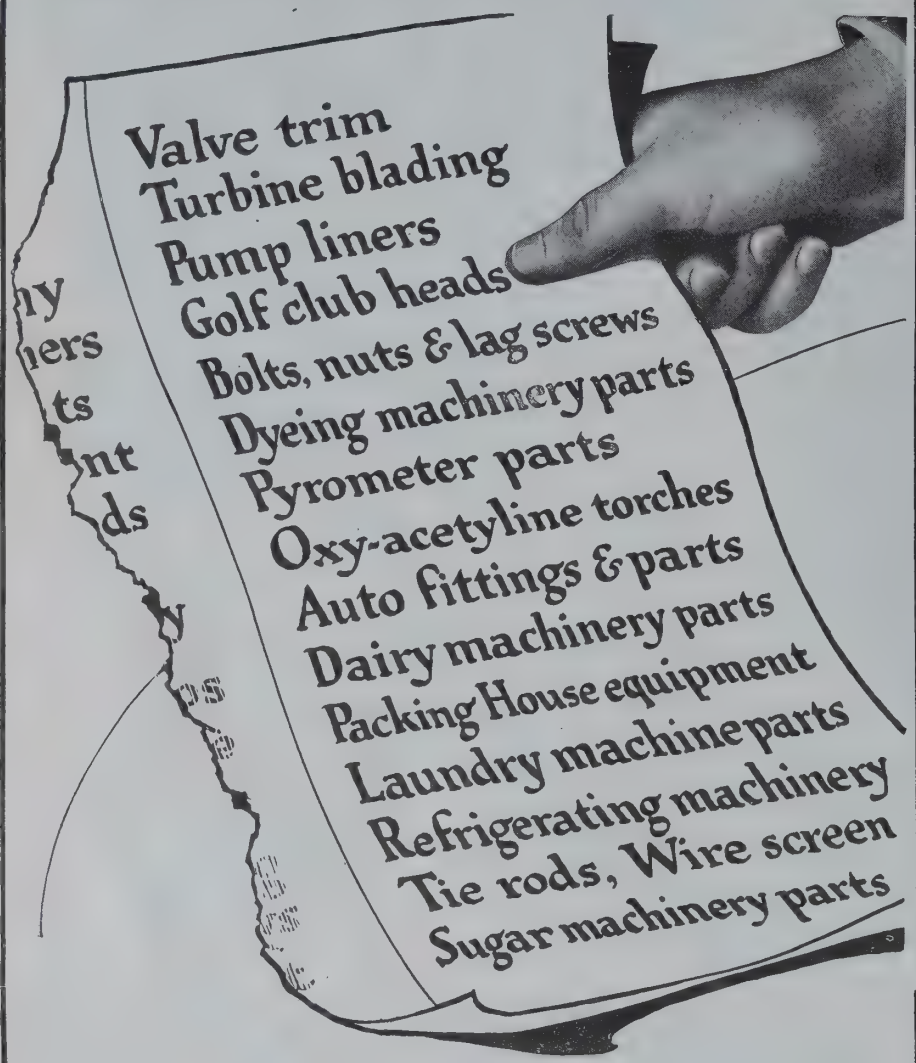
# The service is there when the metal delivers it



YOU pay for the design-time and labor that go to make a metal useful. Then rust, acid action, steam wear, salt pitting and high heats limit its service life and so discount your investment.

These corrosive forces have least effect on Monel metal. In fact such seasoned engineering organizations as J. G. White, Stone and Webster, Dwight Robinson Co., etc., have adopted Monel as standard for anti-corrosive service.

Monel valve seats and stems on 200lb. 125deg. F. superheat lines at the Sherman Creek station, United Electric Light and Power Co., New York, show no wear after six years' continuous service.

Monel shaft sleeves, impellers and runners on condensers and condenser pumps at the Cos Cob Plant of the N. Y. N. H. & H. R. R. have stood up for years against the corrosive action of polluted salt water.

Monel metal for thermo-couples, oxy-acetyline bodies and other heat exposed parts is giving an equally good account of itself in exacting service. (Its ratio of expansion is practically that of steel.)

In chemical process machinery, Monel is specified for filter cloth or for parts directly in contact with active solutions by the best informed consulting engineers.

## New Concepts of the Past Century

(*Continued from page 286*)

with perfect propriety, from the side lines, whether a given geometry is ever realized. We may learn that so far as has yet been discovered there are no elements for which all its postulates are verified, and that there is therefore no realization known. On the other hand, we may more likely find that many different sets of elements are such that the postulates can be interpreted as applying to them, and that we therefore have numerous realizations of the geometry. As a human being the geometer may be interested in all this, but as a geometer it really makes little difference to him.

When we look at space about us, we see it, for some reason grounded in the psychological history of the human race, as made up in the small of points, which go to make up lines, which in turn constitute planes. Or we can start at the other end and break space down first into planes, then into lines, finally into points. Our perceptions and conceptions of these points, lines and planes are very definite indeed; it seems indeed, as the Greeks thought, that certain things about them are self-evident. If we wish to take these self-evident properties of point, line and plane, and combine with them enough additional hair-splitting specifications to assure the modern geometer that we have really a categorical system of assumptions, we shall have the basis of a perfectly good system of geometry. This will be what we unavoidably think of as the absolute truth with regard to the space about us; but you mustn't say so in the presence of the geometer. It will also be what we call the Euclidean geometry. It has been satisfactory in the last degree, because not only space, but pretty much every other system of two or three elements bearing any relations to one another can be made, by employing as a means of interpretation the Descartean scheme of plotting, to fit into the framework of Euclidean geometry. But it is not the only thing in the world of conceptual possibilities, and it begins to appear that it may not even be the only thing in the world of cold hard fact that surrounds us. I had hoped to make clear in this place the reason for these statements and something of their significance; but after repeated boiling down I find that these introductory remarks occupy all the space that can be given to the subject in a single issue, so must postpone the conclusion of the matter till another date. This preliminary discussion will have fulfilled its mission if it has made the layman understand why Bertrand Russell, eminent mathematician, was able to say: "Mathematics is the science in which you never know what you are talking about, or whether what you say is true."

## Running the Gauntlet of Quality Production

(*Continued from page 278*)

sandth of an inch, the tolerance on the hardness is five points on the scleroscope, which is the closest test commercially practicable. Altogether, there are, on this single part, a total of 34 inspection operations, and since many of them must be repeated on each cam, the total number of inspection points is 140. On all the parts named there is one-hundred per cent inspection; that is, every one is inspected. On parts where such great accuracy is not required, the inspections are made on five or ten per cent of the parts, and unless trouble is discovered the balance are passed. Because of this fact, it is impossible to say exactly how many inspections of parts have been made for each car assembled. The number will be above 20,000 and below 25,000.

But if inspection of finished parts is necessary, we must not forget that the foundation of the quality of any product must be the materials that enter into it, and in its methods of selecting materials and handling them the American quantity production system has won a long advantage over the European hand-work system. These methods have now reached a point where nothing is left to chance, and where the exact properties of every piece of metal and of any other material are accurately calculated for the duty it is to do.

The automobile factory of this article purchases 18 fundamentally different kinds of steels, under 45 different sets of specifications, in order to meet the wide range of the needs of a single car. It uses, for the same purpose, seven different brasses, six different bronzes, and so on down the list, each material being chosen to fit a very definite function. Among the non-metallic goods it purchases leather, rubber, wood, glass, felt, fabric, asbestos, cork, gasket materials, bakelite and fibers. The inspection of these materials on their arrival at the plant is only the first step in the process of control.

Many of the materials undergo processes which produce fundamental changes during manufacture. The specifications for the steel alloys, for example, are so varied under heat treatment and carbonizing that it is possible for the factory experts to tell from a single particle of the finished material from which one of more than a hundred working parts it was broken. Finally the Materials Test Division has the added duty of determining from any returned or broken part whether there is any weakness due to manufacture, and recommending changes in specifications to meet it.

For these varied purposes the factory maintains an organization which centers in the laboratories with their expert scientists and elaborate testing machinery, and extends through a system of patrols to every corner of the factory. All materials are watched during processing and not allowed to wait for final inspection to reveal errors. They are constantly held to rigid specifications on all points that at all affect the duties they are to perform.

The testing begins before the purchase of any material, when samples are taken to the laboratories. In these the apparatus is elaborate, covering physical, chemical and microscopic examination. The chemical methods used are checked daily with samples of known content from the United States Bureau of Standards. The physical laboratory includes machinery for testing hardness, tensile machines capable of exerting 200,000 pounds force, torque machines which can exert above 600,000 inch-pounds, and impact machines. The microscopic laboratory is equipped to photograph enlargements of from 30 to 2,000 diameters.

Specifications for purchase of materials are drawn up after the tests on samples have been completed. After delivery of material no lot is permitted to go into manufacture till samples from it have also been tested. This is true whether the purchase is of raw, partly finished, or finished goods, and in the two last named classes of material the specifications have many times been so exacting, and so exactly enforced, that they have resulted in considerable improvements in the factories from which the purchases are made.

To illustrate, the control over a single piece—the ring gear—may be cited. When the steel arrives at the factory it is analyzed chemically for five different elements, which must be in exact proportions. Samples are then heat-treated and tested in the physical laboratories for tensile strength and elasticity. If these are correct, the steel is released, and goes to the forge shop.

There an inspector watches the temperature at which the forging is done. The forged blanks then go for a preliminary heat treatment, where the laboratory inspector checks the pyrometer. There are two heat treatments, then a test for hardness. After being machined the

(*Continued on page 290*)

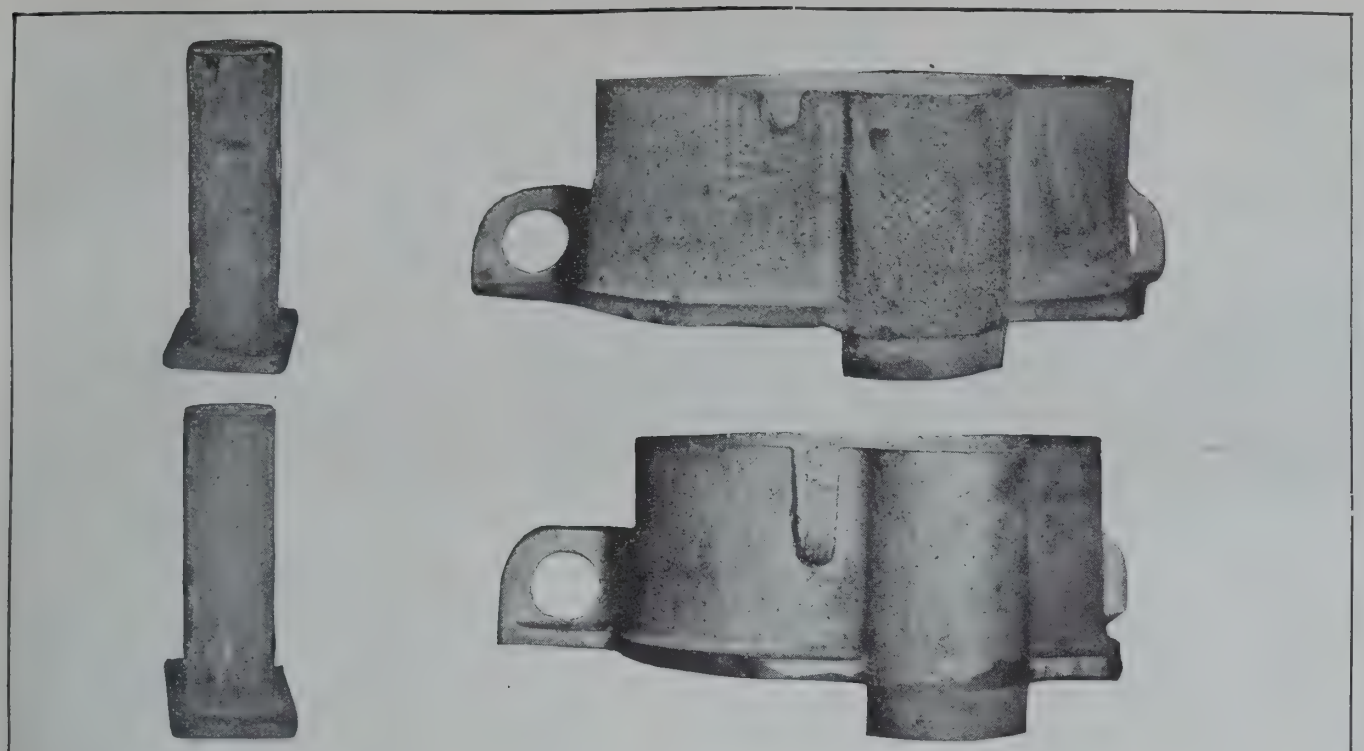

*Fig. 1—(Above) castings produced from hand-made moulds in comparison with (below) the same castings as produced by machine moulding.*

# Increasing the Use of Jigs Speeds Standardized Production

THE man who coined the phrase "doing it in jig-time" was a musician—not a machinist.

On the other hand, the machinist has put the idea to work at far greater profit than has his musical contemporary.

In point of fact the jig comes close to being the foundation of standardized large-scale production. Therefore, any precaution which either increases the applicability of jigs or reduces time in fitting castings to jigs is multiplied in later operations until it mounts into a saving of first importance. Scores of jobs which, in the practice now adopted in machine-shops, go to the layout tables could just as safely and far more profitably be jigged.

Just one condition determines whether the jig-work can be widely utilized in a machine-shop or whether the slower, more expensive layout process must be generally employed. It is a condition which is decided once for all before the machine shop becomes responsible for the progress of the work. It lies solely in the quality and *uniformity* of the casting. Neither adaptable machines nor skillful machinists can remedy the loss of time occasioned by poor castings.

Past foundry practice was built around a faulty understanding of human capacity which still persists in many foundries. The moulder is asked to perform operations demanding two utterly opposed abilities.

First comes the heavy work of shovelling sand and ramming it vigorously into the mould.

Immediately he is called upon to stop this heavy muscular labor and try to perform an operation as dainty as any required of a pianist or artist—he is compelled to attempt to draw the pattern accurately and steadily from the mould without causing the slightest flaw in the delicate sand surface, and without disturbing and breaking the thin walls and partitions of the sand by the slightest quiver of his muscles.

Obviously this method demands too much of any human muscles. The result is that after drawing a mould by hand there is immediate need for painstaking "slicking" and "patching" to repair defects in the mould-surface and delicate partitions. This, however, is merely an attempt but not a real remedy.

In the first place these repairs cannot be accurate because of the obvious inaccuracy of "free-hand" efforts. Secondly the slicked and patched spots in the sand are hardened more densely than other parts of the mould. The gases generated in pouring, instead of escaping freely and evenly at all points, are checked at those dense points, forming pockets of gas and treacherous "blow-holes" in the cast metal.

As a result, when the casting is machined three conditions show up: (1) the pad of finish metal is uneven, demanding extra cuts in many places and thus slowing down production; (2) the uneven texture of the metal is unnecessarily destructive of cutting-tools; (3) blow-holes or lack of alignment compel the scrapping of many castings even after the expenditure of much expensive machine work.

Out of all the centuries in which casting has been carried on it is only in the past fifteen years that the way to solve these obstacles has been found.

The modern cure goes directly to the root of these troubles—it successfully eliminates the uncontrollable variation in every muscular act by substituting machine-power at each step. Moulding machines replace human muscles.

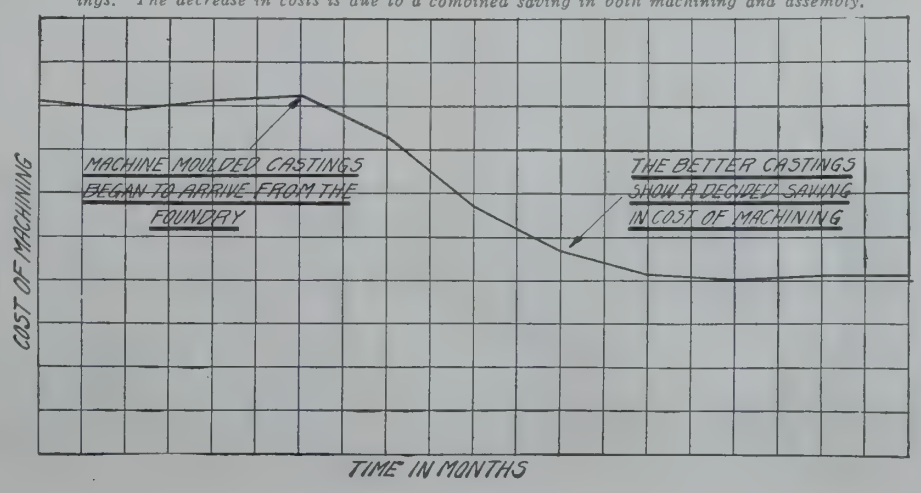
Machine-power rams the sand vigorously but evenly around and over the pattern. It jolts the sand to exactly correct density. It lifts and rolls the flask over smoothly. It draws the pattern without a quiver in true and vertical lift. The mould remains perfect with no need for slicking and patching.

This operation a machine repeats hour after hour through the day without variation. The moulds produced by machine during the fag-end of the shift do not deteriorate nor vary. The castings which come to the machine-shop from a careful machine-foundry are accurate to within $\frac{1}{64}$". This uniformity in size allows the casting to be jigged quickly—a very important and profitable feature. A small casting can be dropped into its jig and it will fit without any adjustment of the jig. A large casting will allow a jig to be placed on it—and again no adjustment of the jig is necessary. The expensive jig thus spends its entire time in useful machining rather than in wasteful adjustments. The uniformly-sized casting not only permits rapid jigging but also rapid machine work—both in the number of cuts to be taken on each surface and in the uniformity of cut. The temper-trying and costly discovery of a distorted casting—after a part of the machine work is done—is also eliminated.

These results are not limited to machining on any particular type of castings but are common to light, intermediate and heavy work.

The saving in maching costs, due solely to the elimination of human muscle in the previous casting operations, averages 17%, a figure reached by combining reports from machine shops operating on widely different types of work. The percentage of defective castings is reduced, on the average, 71%.

*Fig. 2—The graph below shows a typical result of a change from hand-made to machine-moulded castings. The decrease in costs is due to a combined saving in both machining and assembly.*



# Better Castings
## —and More Per Day

The machine-operated foundry not only builds up a list of more solidly-satisfied customers but at the same time profits from internal advantages.

Machine-production of castings increases output without increasing man-power, maintaining steady de-

## Running the Gauntlet of Quality Production

(*Continued from page 288*)

blank is returned for three more heat treatments, the pyrometers and process on each being carefully checked. Then there is a final test to make certain that the results are as they should be. So much for a single part. The process varies, of course, with each part. Similar watch is kept on all, as well as on the handling and mixing of brasses, bronzes and so forth.

The function of the laboratories does not end with the completion of the car. No product is perfect when first put out, and the labatories watch for "bugs." Whenever any part comes back as imperfect the laboratories gather it in. The microscope is the usual detective here, and it is possible to tell from the structure of the steel almost exactly what has happened to it.

Recently, for example, a front axle was returned with the complaint that it bent. Tests showed that it was soft, and a piece went to the microscope. This revealed an entirely different structure in the steel from that which was supposed to have left the factory, and indicated that the bar had been heated and hammered. With this clue it did not take long to learn that the owner of the car had been in an accident that bent his axle, had then had it straightened at a garage, and was now trying to get a new one on the false ground of imperfection.

But the principal work is of a different nature, and is illustrated on another axle—that for a truck. It was figured by the engineers that an elastic limit of 100,000 pounds for this piece would be ample, but several broke, and the limit was raised to 125,000 pounds, the laboratories specifying a different heat treatment. There was still breakage, and it proved impossible to get a higher strength with the steels available. So the company went into the market with a demand for a new steel and was able to get one that could stand 160,000 pounds. Still there was a little trouble, and under the microscope it was found that the weakness was in the steel itself. This resulted in the arrangement previously cited, under which the laboratories have full control of the heat-treatment. The specifications were changed, and were rigidly enforced, and the trouble disappeared.

A similar series of analysis was made with ball bearings. At first there was no standard, but exhaustive work finally led to the decision that the necessary quality could be secured by a heat-treatment which would produce the rare structure of spheroidal cementite. This has proved satisfactory, and the manufacturers of the ball bearings have improved their whole product to meet the specifications laid down.

In spite of all care imperfections creep in, and the whole series of tests is capped with two final inspections, one of the engine and at the very last one of the completed car itself. This last inspection is made by a department having no responsibility to the production department, and answerable only to the president of the company. It puts the car into operation and checks this on 34 different points, besides a general inspection for appearance.

## From Fish to Food

(*Continued from page 280*)

erable depth, and often in going from one side to another they would walk on the fish, causing considerable damage to those trod on. So the modern method is to place the fish into shallow boxes which are piled one on another so that the fish are brought into the cannery in perfect condition. Since most of the fishing boats operate within 20 or 25 miles of the canneries, it is merely an hour or two after being caught that they are delivered ready for canning, and they are processed immediately upon receipt at the

LEGAL NOTICES

PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

cannery. The capacity of the sardine boats ranges from 4 to 10 tons, and practically all of them are operated by gasoline engines.

A novel method of locating sardine schools was tried out recently in southern California, and so successful did it prove that a definite scheme has been worked out by the fishing companies. The scheme is to use hydroplanes to skim close to the surface of the water and watch for the schools, and when discovered word is instantly sent to the waiting boats, which go to the locality of the fish. So far, the seaplanes used have been those attached to the Naval Air Station at San Diego, and as these machines are equipped with wireless outfits the aviators can keep in instant touch with their headquarters. When a seaplane sights a school of fish it wires back to the aviation field from where the information is telephoned to the Fish and Game Commission office at San Diego for distribution to the several canneries in the vicinity.

When the sardines are brought to the cannery, they are hoisted out of the fishing boats in large buckets, weighed and placed in large storage tanks until required for the cutting tables. Surrounding long work tables are large numbers of women who remove the heads and entrails of the fish. The bodies are then placed in large washing-vats, where they are thoroughly cleaned before being spread on flaking trays. These trays are either placed in the sun for the fish to dry or they are run through drying ovens. The tails are next removed and the bodies trimmed to the desired size.

The smaller fish are then fried in olive oil, drained, cooled and sent to the packing table. The larger fish are placed in cans which are inverted on trays and placed in steam vats where the fish are cooked and drained at the same time. The requisite amounts of olive oil and salt are then added, the cans sealed and heated in retorts, and later tested, labeled and packed in cases. To meet the different demands of the trade, the sardines are put up in a variety of sauces, including olive oil, cottonseed oil, tomato catsup, mustard and souse.

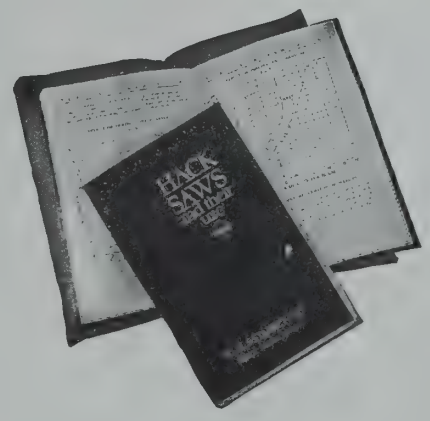
The broken bodies and the parts trimmed off in fitting the fish to the cans are made into sardine paste, and the waste parts are cooked, the oil pressed out and the residue made into chicken meal and fertilizer.

The waste in the sardine industry affords excellent material for the preparation of a high-grade fish meal. As it comes from the packing table it has been steam cooked and partially dried in the process of preparing the fish for packing, and can be taken after collection from the packing tables directly to a plant equipped for pressing and drying.

In an experimental plant maintained by the government it was found that from 27 to 33 per cent of meal could be obtained from the fish residue, and from raw materials containing from 12 to 17 per cent of oil, over one-half of the oil was removed by pressing. The oil obtained was bright, clear, and of very high quality. The fish meal from excessively fat fish contained 17.51 per cent of oil. After pressing and drying raw material which contained from 8 to 9.5 per cent oil, a dried meal was obtained containing from 9 to 12 per cent of fat. The meal obtained from this government experimental plant was sent to various points where it was used in feeding experiments with dairy cattle, poultry and pigs. The preliminary experiments conducted with dairy cows were sufficiently satisfactory to warrant a more extended study of the value of fish meal as a dairy feed, and this is now being conducted by the Dairy Division of the Department of Agriculture. The experiments with hens and and pigs were likewise satisfactory, and there will probably be a sufficient market to utilize all of the by-products from the sardine industry.

**Using hack saw blades right is a man's size job. Takes experience—a lot of it.**

"Hack Saws and Their Use" is a book based upon experience. We've been making blades for years, so we know something about hack saw steel, the pitch, shape, and set of the teeth, tempering, etc. We've put that into the book.



**Then we've had a lot of experience using blades. We've tried different cutting speeds and pressures, made them cut all sorts and shapes of materials, with and without lubricants, timed the cuts, figured how much each cut cost. And what we've learned from that has gone into the book.**

**Every one of its 64 pages contains something worth while about hack saws. If you want to know how your cutting costs may be lowered write for "Hack Saws and Their Use." It's sent free to hack saw users. Address Dept. "B."**

# Use Starrett Blades

## Using the Hand Hack Saw

Because a hack saw is so simple a tool, it is one of the most abused. Most of the waste in breakage, and most of the blame for inefficient cutting is due to the inexperience of the user rather than to lack of quality in the blade. Even a little instruction is thoroughly worth while in the interests of hack saw economy.

To quote from *Hack Saws and Their Use*, just published by The L. S. Starrett Company:

"In hand work, see first of all that the blade is well strained in the frame, with the rake of the teeth such that it will cut on the forward stroke. A flexible-back blade, because it lacks natural rigidity, should be strained tighter than an 'all-hard' saw. A properly strained blade, when 'thumbed,' gives a clear, humming note, which, once heard, is easily remembered. In using a flexible blade, the tension should be increased when cutting as the blade stretches while in use.

"If possible, lock the work securely in a vise. In cutting sheet metal, if the gage and size will permit, place the work in a vise so that a flat surface, rather than an edge, is in contact with the saw. If this is impracticable, put a light strip of wood on either side of the sheet of metal and cut through both the wood and metal at the same time.

"Always place the work in the vise so as to provide as great a bearing for the saw as possible. That is, set the work, if a piece of structural steel, channel or similar material, so as to engage the maximum number of teeth throughout the cut. When placing work in a vise, the tendency of coarse teeth to 'straddle' must be borne in mind, and also that the fewer the teeth engaged at any particular moment during the cut, the greater the strain on each tooth, and consequently the greater likelihood of stripping the blade.

"Start the cut slowly, using the same motion as in filing. Put on enough pressure to make the blade cut, and not slip or slide over the metal. Too little pressure in the first stages of a cut will take more out of a saw than fifty cuts made under proper conditions. By starting with a very light pressure, and allowing the saw to rub rather than cut the work, and then increasing the weight at a destructive rate once the first sharp edge is worn off the blade, it is possible to so completely ruin a saw that it will not make one full cut on a two-inch round. On the other hand, care must be taken not to use so much pressure that the teeth will engage the work too rapidly, or stripping of the blade may result. At the end of the forward cut, lift the blade slightly to avoid dragging or rubbing the teeth on the stock during the return stroke. Pressure during the return stroke is a frequent cause of premature loss of efficiency in hand hack saw blades.

"Generally speaking, hand hack saw blades should not travel faster than fifty strokes per minute; thirty-five or forty strokes are even better. Care must be exercised to avoid overheating the blade by too rapid cutting, and so drawing its temper. In hand sawing, it will generally be found worth while, after the first few strokes, to retighten the blade in the frame. This takes up any stretch that may have occurred, prevents drifting and tends to produce better cutting. When using flexible or 'soft-back' blades it is absolutely essential that the saw be retightened during use."—From *Hack Saws and Their Use*, published by The L. S. Starrett Company, Athol, Mass., for free distribution.

**Drop-Forged Tool Makers' "C" Clamps**

The tool maker uses light tools because, for his purpose, extreme strength is unnecessary. Williams' "Vulcan" Tool Makers' Clamps are stiff and strong, yet light—like other Williams' products, they are absolutely dependable.

In four sizes, 1″ to 4″ capacities, with plain screw or removable swivel screw.

**Wireless Telegraphy and Telephony**

Simply Explained By ALFRED P. MORGAN, Wireless Expert

170 Pages 156 Illustrations Cloth Bound

Price $1.25; by mail, $1.35

**The simplest, latest and most comprehensive popular work published on wireless, for the wireless operator, amateur or professional**

THIS is a comprehensive treatise and a close study of its pages will enable one to master all the details of the wireless transmission of messages. The author has filled along-felt want and has succeeded in furnishing a lucid, comprehensible explanation in simple language of the theory and practice of wireless telegraphy and telephony.

The book treats the subject from an entirely new standpoint. Several very novel and original ideas have been carried out in its making. It is well illustrated by over one hundred and fifty interesting photographs and drawings. All diagrams have been made in perspective showing the instruments as they actually appear in practice. The drawings are carefully keyed and labeled. Many of the photographs are accompanied by phantom drawings which reveal the name and purpose of each part.

This is a book the wireless experimenter cannot afford to be without. It enables one to design and construct their own apparatus This book will also prove of value to the layman.

SCIENTIFIC AMERICAN PUBLISHING CO.

Another method for utilizing the by-products of the fish-canning industry is in the manufacture of commercial fertilizers. Fish scrap is rich in both nitrogen and bone phosphate, and as a fertilizer it is worth at least $40 per ton.

In the salmon canning industry it has been found that an average of 30 per cent of the fish that come to the factory is discarded as unsuited for canning. This includes heads, tails, fins, roe and viscera. This raw canning waste contains approximately 3.67 per cent of ammonia; 3.46 per cent of bone phosphate and about 10.43 per cent of fish oil. The waste products from the salmon industry alone would yield annually about 11,400 tons of fish scrap and about 2,500,000 gallons of oil. In addition to the salmon caught, large quantities of other fish are brought in and usually thrown away, which could be utilized for fertilizer.

Keeping pace with the expansion of the sardine canning factories in California are the commercial reduction works which utilize the waste fish. At San Pedro there are several such reduction plants, with a combined capacity of about 1,200 tons of fish per day. In three months these reduction plants handled a total of 15,718,006 pounds of fish, ranging from sharks to sardines, but on some days the run of fish was so great that the plants could not handle them, and in a single day the health department required the dumping out to sea of 185 tons of sardines that could not be handled.

## The Romance of Invention—XVII

(*Continued from page 282*)

which another worked, or duplicate his own work with mathematical exactness.

The use of tungsten as the target or anode has greatly increased the capacity of the tube for both life and work, on account of its resistance to heat. Under the bombardment of electrons from the hot cathode the target gets greatly heated—indeed, it is perfectly possible to melt even a solid tungsten target if no artificial cooling is resorted to, because more than ninety-nine per cent of the energy input in an X-ray tube is changed in the target into heat. Dr. Coolidge has devised several different systems of cooling, using water, a radiator and a fan, a radiator which is air-cooled direct, and an oil-immersed tube which obtains better cooling as a by-product of its construction, the real reason for immersing the tube in oil being to eliminate the danger of electric shock to operator and patient.

Dr. Coolidge is constantly experimenting on X-ray tubes and accessories. One of the latest developments is the air-cooled, radiator-type tube. To understand the real importance of this improvement it is necessary to remember that while a solid tungsten target tube is capable of rectifying its own current, it does so only with such amounts of energy input as do not heat the target to a temperature approximating that of the cathode. When such a degree of heat is reached the target begins emitting electrons, and if the energy supplied is an alternating potential, an "inverse" current passes. This "inverse" cathode-ray stream hits the glass just behind the cathode, heats and usually cracks it, and of course ruins the tube. The trouble is cured, as far as danger is concerned, by having a cathode-focussing device of either tungsten or molybdenum, which is so designed as to intercept the "inverse" stream; but while efficient as a safety device this does not permit an increase in capacity of the tube. What is wanted is more power in one stream of X-rays, not two streams from two different points.

To increase the capacity of a self-rectifying tube it is necessary to take away heat, so that no "inverse" current shall be formed. Moreover, without some cooling system, the waits between operation for cooling of the heated target are long. With the fin-type radiator of copper connected to a copper anode-arm with a tungsten target (copper being a much better conductor of heat than tungsten) the tube can be used much longer than with the usual uncooled tungsten anode, without undue heating; and it cools with relative rapidity between uses, because of the good conduction and radiation of heat by the copper anode and fin radiator. Inasmuch as in the new tube, the greater part of the heat energy is radiated through the radiator and not through the glass, the glass tube may be much reduced in size (3¾ inches is now a standard).

Another contribution to the physician which has recently come from Schenectady is the portable X-ray outfit, which attaches to any lamp socket and may be carried in a physician's automobile. The advantages of carrying the apparatus to the patient rather than the patient to the apparatus are obvious. Indeed there are many cases where lives might be saved could X-ray pictures be made, which must be lost because of the impossibility of moving the patient. Time and expense are always to be saved by the use of a portable X-ray outfit, not to mention suffering, as in the case of broken bones, which should be photographed. This however entails difficulty and pain if the patient must be ambulanced to a hospital and back again.

The portable outfit includes a stand to hold the tube, a transformer and a control apparatus, which is so simple as to be fool-proof and which also makes automatic exposures possible. The tubes to be used with this outfit are of a new, small type made of very thick glass which is fifty-five per cent lead, giving the same protection to operator and patient as a one-sixteenth-inch sheet of pure lead. The X-rays can escape from the tube only through a small window of lime glass.

Dr. Coolidge's work must be considered in the light of the great resources supplied him by the electric company and the facilities and assistants provided. Dr. Coolidge desires that full credit be given the many assistants who have helped in the development of ductile tungsten, the hot cathode tube and the other improvements made in X-ray outfits. For instance, were it not for the Langmuir mercury-vapor vacuum-pump no such high vacuum as is now produced in X-ray tubes would be possible. Without the conveniences and the disregard of necessary expense for lengthy and tedious investigations, no such developments as have taken place in either the arts of making over the most refractory metal in existence into a tractable substance, or of producing X-ray tubes which are instruments of precision rather than hit-or-miss X-ray producers, would have occurred.

In the development of Roentgenology lie the greatest possibilities both for the cure of certain difficult ailments to which the human machine is subject and the diagnosis of others which, without some such investigatory methods, can be treated only by hope and guess work. It is well realized that the science is only in its infancy, and that, with increased penetration, that even approaches the most penetrating radiations of radium in character, much that is new is yet to be discovered and much that is helpful is to be developed. The man whose efforts have accomplished so much in this department of research is young, enthusiastic, vitally interested in his work, and with plans made ahead which already promise even more interesting developments and discoveries than those which he has already to his credit. He is to be congratulated upon having found a place in the organization for which he labors, but the general public is even more to be felicitated that the great research laboratory at Schenectady should have made its own so original and enthusiastic a scientist as the subject of this sketch.

# Steam Hose Must be Reliable

Modern steam engineering works with such high pressure and high temperature as to require steam hose that is absolutely reliable, as failure at a critical moment might result in a serious accident.

The inner tube must resist heat to the utmost—the body must have great strength—the cover must resist rough usage.

Rainbow, Giant, and Perfected Steam Hose are designed to meet varying requirements of service.

We will gladly recommend the proper brand for your work if we are given full information as to your operating conditions.

# The Beginning of the World's Second Largest Industry

GEORGE B. SELDEN invented, in 1877, the first internal combustion gasoline engine for road locomotion. This was the beginning of the world's second largest industry.

History affords no more startling record of achievement than the development of the automotive industry, which resulted from this remarkable invention by Selden.

SELDEN TRUCKS have shared in the development of this second largest industry. Wherever in the world there has existed a need for dependable, economical, profitable haulage of commodities, SELDEN TRUCKS have served and proved their ability.

SELDEN TRUCKS possess tremendous strength of construction and enormous pulling power. Actual records of users prove their cost of operation and maintenance to be low. There are no better trucks than SELDEN TRUCKS.

Ask us to give you facts that will show how SELDEN TRUCKS are effecting economies in your line of business.

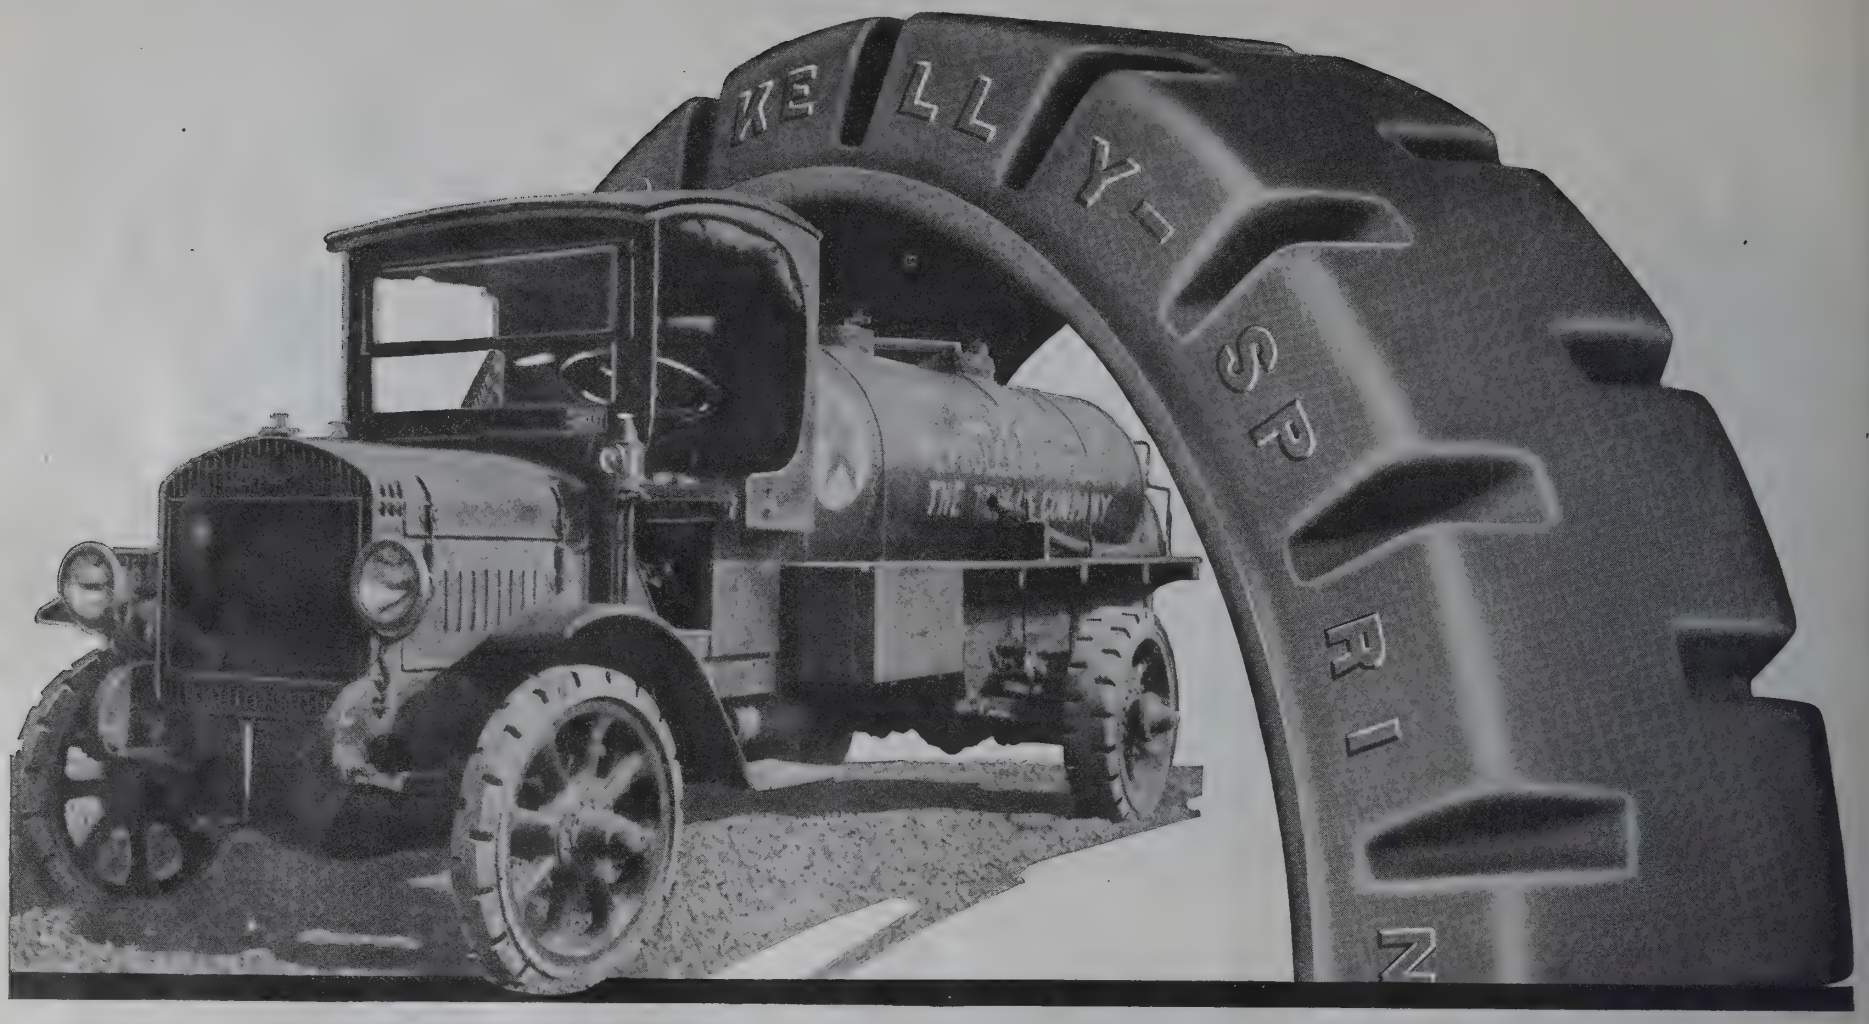
THE SCIENTIFIC AMERICAN. September 25, 1920. Volume 123, Number 13. Published weekly by Scientific American Publishing Company at 233 Broadway New York, N. Y. Subscription price, $5.00 per year.
Entered as second-class matter June 18, 1879, at the post office at New York, N. Y., under the act of March 3, 1879.



# Hard going doesn't stop these wonderful tires

"One thing we like about your Caterpillar tires," writes a big contractor, "is the traction our trucks are able to get with them. Only under the most exceptional conditions do we have to use chains. No matter how heavy the load, our trucks never have any difficulty in climbing out of excavations, and we find that Caterpillar equipment means a substantial saving in gasoline consumption."

The Caterpillar's amazing traction qualities seem to be the feature most frequently commented upon by truck owners; but it has two other equally important advantages.

It cushions the truck, and it gives double the average mileage of any other type of tire.

More resilient than a solid tire, more dependable than a big pneumatic, and giving greater mileage than either, it is not surprising that the Kelly Caterpillar has become almost exclusive equipment on some of the largest fleets of trucks in America.

**Broken-away view of a locomotive fitted with the new booster, showing how this device is applied; a view of the rear end of a locomotive so equipped; and a view of the two-cylinder engine and gear drive comprising the booster**

## More Starting Power for the Steam Locomotive

THE locomotive booster is a power unit applied to the trailing wheels which, by utilizing their full traction, increases the drawbar pull by 25 to 40 per cent (depending upon the type of locomotive) at starting and getting up to road speed, and disengages automatically when the engineer hooks up the reverse lever. This device capitalizes idle weight and spare steam with negligible addition to the weight of the locomotive, and without increased demands on the engineman. Its control is semi-automatic, giving the engineman a maximum resource with a negligible minimum of attention to its operation.

Locomotives recently built employ weights bordering on the limit the track structure will bear. Yet their speed-pull curves nearly coincide with those of lighter engines of the same type. Greater starting and accelerating power is the principal advantage.

The locomotive booster, so it is claimed, gives an increase in starting and accelerating power equal to what 50,000 pounds additional locomotive weight would give. And the booster weighs only 3,500 pounds. So it may be said to avoid large investments for improved roadway and bigger locomotives.

This remarkable device has been hailed by many experts as the greatest advance in steam locomotive engineering in ten years. It reduces by one-half the time required to get trains to road speed. It is said to pay its own fixed and maintenance charges several times by avoiding slipping drivers and the consequent wear and tear on the main locomotive. When the train is up to road speed it has no more effect on the locomotive's operation than so much coal on the tender.

The booster consists of a simple two-cylinder steam engine, secured to and supported by a specially designed cast steel bed plate. This cast steel bed plate contains the axle bearings and supports all moving parts of the booster. Three-point support is provided, two bearings fitting on the trailing axle and a third, which is a ball joint, fitting on the back member of the trailing truck frame. This suspension gives sufficient flexibility to compensate for any torsional movement between trailing truck frame and axle, and in addition the ball joint is located near the center of gravity of the booster engine, thereby relieving the trailing axle of the weight and minimizing wear of the booster bearings.

The piston rod, connecting rod and crank-shaft follow general locomotive practice. The crank-shaft and driving piston are integral and are of heat-treated steel, liberally designed. Lubrication is taken care of by enclosing the entire engine and connections in an oil-tight steel case and using splash method. This automatically lubricates all bearings except the main bearings on the trailing axle, which are lubricated in the same manner as is employed for car journal boxes, *i. e.*, a waste-packed oil box.

The control valves are air-operated. Indeed, practically push-button control is provided. Nothing is left to judgment except the use of the device when needed. All the engineer has to do is to raise the latch on the reverse quadrant. Operating the locomotive in the usual way automatically operates the booster. It can only be brought into operation when the latch on the reverse lever quadrant is in operating position, when the main locomotive throttle is open,

# SCIENTIFIC AMERICAN

**Published by Scientific American Publishing Co.**
**Founded 1845**
**New York, Saturday, September 25, 1920**
**Munn & Co., 233 Broadway, New York**

Charles Allen Munn, President; Orson D. Munn, Treasurer
Allan C. Hoffman, Secretary; all at 233 Broadway

Entered at the Post Office of New York, N. Y., as Second Class Matter
Trade Mark Registered in the United States Patent Office

Copyright 1920 by Scientific American Publishing Co.
Great Britain rights reserved
Illustrated articles must not be reproduced without permission

*The object of this journal is to record accurately and lucidly the latest scientific, mechanical and industrial news of the day. As a weekly journal, it is in a position to announce interesting developments before they are published elsewhere.*

*The editor is glad to have submitted to him timely articles suitable for these columns, especially when such articles are accompanied by photographs.*

## An Announcement

IT is with great regret that we announce the necessity of increasing the subscription price of our publications—a necessity imposed upon us by abnormal conditions in the publishing business. At present prices and under present conditions our publications can be produced only at considerable loss. Our manufacturing costs, barring the single item of paper, have increased 200 per cent; the cost of paper has increased 300 per cent since the beginning of the war; postage under the zone legislation has increased 200 per cent. Like most other publishers, we have hesitated to take the drastic action necessary to meet these increases, until it had become entirely clear that it was a permanent rather than a temporary condition that faces us. Stabilization of business on a new basis has gone sufficiently far for us to be assured now that this higher level of costs will not be materially abated, at least for a long time. In company with conservative publishers everywhere, we therefore find it necessary now to readjust the selling price of our product to conform with the new conditions.

Beginning October 2nd, the price of the SCIENTIFIC AMERICAN will be advanced from five to six dollars, annual subscription; that of the SCIENTIFIC AMERICAN MONTHLY will be advanced from five to seven dollars, annual subscription.

In spite of the serious difficulties which have confronted the publisher during the past twelve months, the high standard of the SCIENTIFIC AMERICAN has been maintained, and the subscriber has been given the same excellent quality of reading matter that we have furnished in the past. The same will be true of the future; we shall continue to cover as we have always covered our field of applied mechanical science, invention and industry.

While it would be impossible to catalog all the features of the coming year, and wearisome even if it were possible, several outstanding high lights clamor for mention. A kind friend of the SCIENTIFIC AMERICAN has offered a prize of five thousand dollars for the best essay on the Einstein theories of relativity, and every thinking person will want to read the winning essay and its close competitors when these begin to appear in our columns. Earnest watchers of the stars follow our monthly astronomical article by Professor Russell with great interest. The tale of the successes which great inventors have attained through the establishment of commercial plants and the development of their inventions will continue in the series of articles "The Romance of Invention." The extraordinarily useful summaries in briefest possible form of the achievements of science and technology here, there and everywhere will continue to make the SCIENTIFIC AMERICAN of the greatest value to the busy man who must know what the world is doing. In the future as in the past the progress of aviation and the other new arts will be fully chronicled.

It is the purpose of the SCIENTIFIC AMERICAN, almost before all else, to publish up-to-date articles upon the latest inventions that are brought to public notice. These discussions are timely and full of interest. It is the policy of the editor, and has been so ever since the days of the notorious "Keeley Motor," to expose fictitious claims which are put forward from time to time in regard to some startling discovery of doubtful authenticity, an especially valuable activity when such claims seem to be developed for financial reasons. The paper is designed to keep the reader informed of the latest news of the day along its particular line, and anyone who is a constant reader of the SCIENTIFIC AMERICAN will find himself to be better informed by such reading, not alone with reference to his own particular line of work but as to what is going on in the scientific and industrial world at large.

## To Render Travel by Air Safe

TO those of us who wish to see the future of commercial aviation assured, it is extremely disconcerting to notice that the number of fatal accidents in aviation appears to be on the increase, and this increase, it should be remembered, is not by any means proportional to an increase in the number of machines and pilots; for the rate of increase of accidents is out of all proportion to the growth of flying as a sport and a commercial industry. The details of these ever-recurring accidents as given in the daily press show that far too many of them are due to exhibition flying, air "stunting" and the demands of the "movie" men and the daily press for sensational and novel pictures. Another contributory cause of disasters is the great scarcity of flying fields and proper landing places at a time when great efforts are being made to promote long-distance travel by air.

There can be no denying that the situation is such as calls loudly for government assistance and control. Any day of the year airplanes may be seen flying low over cities and villages, and it is only a month since a machine engaged in photography narrowly missed crashing among an assembled crowd of 10,000 people. There is a growing note of protest against these practices, and it is fully justified by the serious risks to which the public is daily being exposed. We have heard a good deal of talk during the past two or three years about the need for legislation and the formulation of strict laws governing the use of the air; but if any such rules, State or municipal, exist, they are honored more in the breach than in the observance.

The evil of all this lies in the effective way in which it tends to kill that public appreciation and confidence, which is absolutely necessary if commercial aviation is to make any headway in the United States. Unquestionably the perpetually recurring disasters of the past few months, a large proportion of which have happened to skilled pilots of long experience, is doing much to shake public confidence.

That we are not playing the part of alarmists or unduly exaggerating the increasing flying accidents is proved by the fact that in Europe they have found a means to make flying the safe and attractive form of travel which it is entitled to be. Testimony to the truth of this statement comes from that well-known and successful designer of airplanes, Edson F. Gallaudet, who with his associate, W. B. Lebherz, has just returned from a two months' tour of Europe, where they found that the aircraft industry is in the midst of extensive experimentation out of which it is expected there will be evolved new types of material and construction for long-distance aerial transport. In this important work, we are told, the manufacturers even in Germany are receiving the active support of their governments. This support in the case of England and France does not take the form of large appropriations, but consists of the passage and enforcement of laws regulating aerial traffic; licensing of pilots and inspection of aircraft; the prosecution of technical investigations into new metals and alloys which will increase the safety and enhance the durability of machines; and, finally, in the appropriation of small amounts for experimental development sufficient to enable the manufacturers to remain in business, thereby assuring the possession of construction facilities in case of future national need.

Mr. Gallaudet ascribes the present unsatisfactory condition of our airplane industry to the fact that we do not have the advantage of the national coöperation which is enjoyed abroad. He believes that this lack is reflected in America in the repeated number of fatal accidents following our disregard for the common rules of flying.

Thus, we are told that during the two months these gentlemen were in Europe, there was only one airplane accident in England and none in France or Germany of which they heard any mention or saw any record. The result of this immunity is that abroad there is a general confidence in the safety of air travel. They attribute the scarcity of accidents abroad to the existence of severe regulatory national laws and their strict enforcement by centralized aeronautical branches of the Government, which normally makes improbable the dangerous practices which are common in the United States. As an instance of this, they quote the fact that in England a flyer was fined $250 in police court for making several Immelman turns at a height of 500 to 600 feet from the ground. They were given an opportunity to study the actual results of the British national policy of regulating flying and encouraging its development by making it safe. They found that in the preceding twelve months within the British Isles alone, nearly 700,000 miles had been flown by airplanes of all types with only 24 accidents and 4 fatalities.

## Setting Our Industrial House in Order

THE conclusion of the war found the nations of Europe with empty storehouses and their stocks of a thousand necessary commodities, both raw and finished, depleted. Until such time as they could set their house in order, they turned to the United States as the only possible provider on the enormous scale demanded by their crying necessities, with the result that our export trade expanded by leaps and bounds to unbelievable figures. It was realized that the conditions were temporary, and the unfavorable rate of exchange, coupled with the unexpectedly rapid return of European industries to normal peace-time conditions, had the inevitable result of greatly reducing the volume of our export trade to Europe.

The slowing down of the foreign demand should have a most favorable effect on the solution of our own great problems of readjustment and reconstruction. Not alone during the war but also in the two years that have passed since the armistice, the industrial effort of the United States has been diverted from its own internal necessities. Our vast railroad system has been so greatly neglected that a conservative estimate by expert railroad officials has placed the total expenditures that must be made before the railroads have caught up with the enormously increased traffic demands, at the huge figure of five billion dollars. Recent favorable legislation and the belated increase in rates will render the railroads, it is hoped, so desirable an investment as to lead the public to invest on a sufficiently generous scale to provide the funds for reconstruction as they are needed.

Another equally urgent domestic problem, intimately bound up with the railroad problem, is that of housing. There can be no return to normal conditions until the present distressing shortage has been relieved. In no direction was our diversion of effort, both during the war and after, so grievously felt as in this matter of providing homes for the people to live in. That a man shall have a roof over his head is a demand only less insistent than that he shall have food in his mouth.

The capital and energies that have been spent so freely in supplying the needs of an impoverished world should now be concentrated very largely on the task of providing sufficient houses for the people to live in. In this matter we have not shown the enterprise with which some of the debt-burdened nations of Europe have taken hold of the problem. There has yet to be formulated a broad, well-thought-out plan; and it would be well if the leaders of both parties would substitute for the reprehensible politics of the day, to which the public shows a contemptuous indifference, a little real constructive legislation on a subject in which the whole country is vitally interested.

There is no doubt that agriculture has suffered greatly by the influx of workers from the country to the cities as the result of the abnormal industrial demands of the war and the post-war expansion of our export trade. Already the closing or slowing down of industrial plants is causing a reversal of the tide of labor. The flow is now from the cities to the country, and agriculture—basis of permanent prosperity—seems about to come, once more, into its own.

## Naval and Merchant Marine

**The New Navy Hangar.**—The new naval hangar at Lakehurst will accommodate two dirigibles, both more than twice as large as R-34. In fact, it will be larger than any hangar in existence. The length is nearly 1,000 feet, the width, 318 feet, and the height, 210 feet. The double doors are each 177 feet high and 136 feet wide.

**A Record Parachute Drop.**—The official record for a parachute drop has been accredited to Lieutenant John H. Wilson, U.S.A., of the 96th Aero Squadron, Kelly Field, Texas. There has been a question as to whether a parachute would open satisfactorily in rarefied atmosphere. The Lieutenant demonstrated that it would when he leaped from an army airplane at an altitude of 19,861 feet, and seventeen minutes later made a safe landing.

**The Question of Personnel in Our Navy.**—Representative Fred A. Britten, of the House Committee on Naval Affairs, is right when he says that we should now give our attention to the rounding out of the fleet, the development of the merchant marine and the securing of an adequate and well-trained personnel. The first step to be taken is to secure men for the new ships which are now under construction. The Navy should give equal if not greater attention to the question of personnel than to that of the completion of our new battleships and battle-cruisers.

**Panama Canal Traffic.**—Traffic through the Panama Canal for the year ending June 30, 1920, exceed that of any previous year. A total of 2,478 merchant ships passed through the Canal with an aggregate net tonnage of 8,545,653 tons. In the fiscal year 1918-19, 2,025 ships pased through the Canal, and their aggregate was 6,131,575 net tons. The aggregate revenues approximated $8,800,000, and the expenses of operation and maintenance were about $6,650,000. This, however, takes no note of the interest charges on the cost of the Canal or of the depreciation of the plant.

**Our Latest Battleships and Battle Cruisers.**—Our latest battleships of the "Indiana" class, of 43,200 tons displacement and 23 knots speed, carrying twelve 16-inch guns, will be electrically driven. The turbines of 60,000 combined horse-power will develop their full rated load at 265 pounds pressure, 50 degrees superheat, and 28½ inches vacuum. The six new battle-cruisers of 43,500 horse-power and 35 knots speed, carrying eight 16-inch guns, will also be driven electrically. Two of them, the "Ranger" and the "Constellation" will carry four Westinghouse turbines of 49,750 brake horse-power, the current from which will be developed on eight Westinghouse motors, each of 22,500 horse-power.

**Franklin Medal to Sir Charles Parsons.**—The Franklin medal has been awarded to Sir Charles Parsons "in recognition of his epoch-making success in the development and the construction of the steam turbine which has revolutionized the art of steam engineering, particularly in regard to the propulsion of mercantile and naval vessels, and the driving of electrical generators." Not many people know of the courageous struggle of Sir Charles in the early days of his invention, and that he separated from his original partners owing to their becoming too discouraged to "carry on." *Engineering*, in speaking of the ward, says: "The work of Sir Charles Parsons has halved the cost of producing electric power and reduced in still greater proportion the capital cost of engineering machinery."

**The World's Merchant Shipping.**—It is estimated by Lloyd's that as a result of the action of enemy submarines and the diversion of resources normally employed in replacing losses and constructing new tonnage, the net reduction in the merchant shipping of the world during the last six years amounted to 3,516,000 tons, this figure being based on the assumption that the ratio of increase during the last six years would have been four-fifths of the average rate of increase during the previous six years. The United Kingdom leads with 18,111,000 tons, and the tonnage for the whole empire, including the British Dominions, is 20,143,000 tons. The United States comes next with 12,406,000 tons, the total for this country having thus grown since 1914 when it was 2,027,000 tons.

## Astronomy

**The Total Number of Minor Planets.**—M. Paul Stroobant, director of the Royal Observatory of Belgium, has made an estimate, by two different methods, of the total number of asteroids, or minor planets, brighter than the 20th magnitude. The result, according to one method, is 57,000, and, according to the other, 100,000. M. Stroobant believes that very few of these bodies brighter than the 12th magnitude remain undiscovered.

**A Minor Planet Mistaken for a Comet.**—According to *Astronomische Nachrichten*, it has been discovered by F. K. Zweck that the object heretofore known as Comet 1908 *a* (or, in some catalogs, Comet 1907 VI) is identical with the minor planet 516 Amherstia. This body was at first taken for Encke's comet, and afterward for a new comet with a large perihelion distance. The orbits of Encke's comet and Amherstia approach each other within 2,000,000 miles in about longitude 310 deg. and within 5,000,000 in about long. 358.

**Unexplained Irregularities in Lunar Motion.**—In a recent address before the Astronomical Society of the Pacific on "The Problem of the Moon's Motion," Prof. E. W. Brown discussed, *inter alia*, the curious semi-regular fluctuations of the moon from its theoretical position first discovered by Newcomb. The earth, Mercury and Venus have been found to exhibit deviations of a similar character, though smaller in amount. The irregular character and comparatively great magnitude of these fluctuations, says Prof. Brown, suggest that there is some set of forces acting on the bodies of the solar system related to the known irregular changes in the condition of the sun. The period of rotation of the sun's magnetic axis found at Mount Wilson is sufficiently close to that of one of the principal lunar periodic terms known as the evection to suggest a long-period change by the phenomenon known as resonance. Long continued observation will, however, be necessary to enable us to ascertain the merit of this suggestion.

**A Century of the Royal Astronomical Society.**—The annual general meeting of the Royal Astronomical Society held last February marked the hundredth anniversary of the foundation of the society, the early history of which was set forth in Prof. Fowler's presidential address. The organization was launched at a meeting held at the Freemasons' Tavern, in London, Jan. 12, 1820, and the prime mover in the undertaking appears to have been the Rev. W. Pearson. The first general meeting of the newly constituted society was held at the rooms of the Geological Society Feb. 8, 1920, thus establishing the custom still maintained of holding the annual meetings in February. The Duke of Somerset was elected president but declined to serve, and the first actual holder of the office was Sir William Herschel. The *Monthly Notices* of the Society, now an indispensable part of the reading of astronomers throughout the world, date from 1827. In 1830 King William IV became patron of the organization and its name was changed from the Astronomical Society of London to the Royal Astronomical Society.

**To Determine Australian Longitudes by Radio.**—In marking out the boundary between South and West Australia, defined by imperial act as the 129th degree of longitude east of Greenwich, it is proposed to determine an initial point on the line by utilizing longitude signals from a high-power radio station located at some point between Greenwich Observatory, in England, and Sydney Observatory, in Australia, the signals to be received simultaneously at these two points. This undertaking will be the first step in a comprehensive scheme involving the redetermination of the whole longitude system of Australia. A committee has been appointed to carry out the work in Australia, comprising the government astronomers of New South Wales, Victoria, West Australia, and South Australia, the commonwealth surveyor-general, and the director of the Royal Australian Navy Radio Service. It has been ascertained that, under favorable conditions, signals from Lyons can be successfully received in Australia as well as at Greenwich, and signals from other stations more symmetrically situated are also being tested. The coöperation of the United States, as well as the British Government, has been invited.

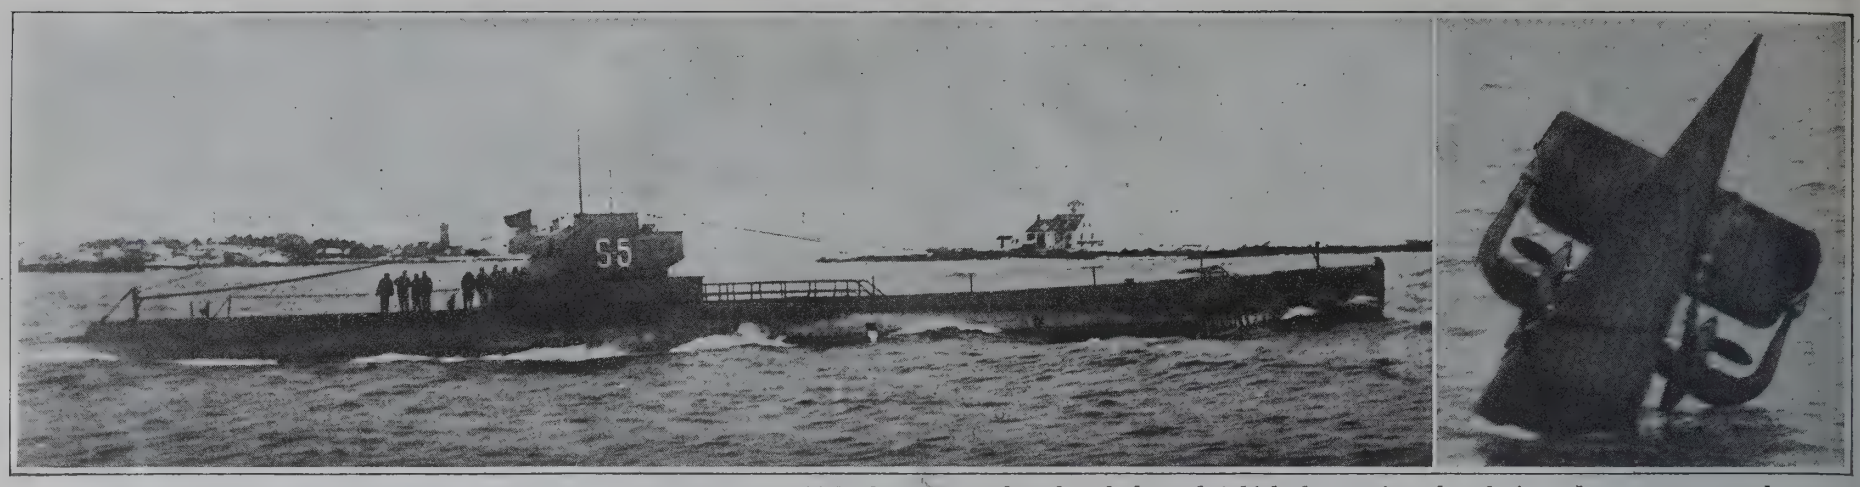
## Automobiles

**Material Market Limits Car Production.**—One of our mechanical contemporaries, *Machinery*, states that the automobile industries appear to be fairly well supplied with machine tools for present requirements, though some of the larger companies are still buying. Gear manufacturers are exceedingly active, and a large percentage—in some cases from 75 to 80 per cent—of their product goes to the automobile and truck industries. It is estimated that the output of the automobile and truck builders for this year will amount to 2,250,000 cars. It may not be possible for all the automobile builders to complete as many cars as planned on account of the decided shortage of certain classes of material. Sheet steel is scarce, and cold-rolled stock of some sizes can be had only in small quantities. This is a serious drawback in the metal-working industries.

**Belgian Auto Industry.**—Before the war there were twelve automobile factories in Belgium, located in the neighborhood of Liege, Charleroi, Brussels and Antwerp, employing 4,000 to 5,000 men. The annual production, chiefly private cars and motorcycles approximated 4,500 to 5,000 automobiles and chassis and 7,000 to 8,000 motorcycles, with a total value of some $11,000,000. Mass production in series of standard types of automobile is not characteristic of the Belgian plants, but special attention is given to the construction of engines and in satisfying the foreign market, especially South America, as to form and decoration. There is a market in Belgium at the present time for American automobiles. The machines desired are those of a moderate price. It is necessary that they be strongly built as many Belgian roads are of cobblestone construction.

**Inspect Ignition System.**—The ignition system of an automobile should be inspected carefully to learn if all wires are intact, that the terminals are bright and clean, and the insulation is not saturated with oil or grease. The terminals should all be soldered and the wiring should be taped wherever it may chafe. The spark plugs should be taken out, disassembled and cleaned with gasoline. If the porcelains are heavily coated with carbon they can be soaked in kerosene until it softens, when it can be wiped off. Don't scrape the porcelain, as this may remove the glaze. The shells should be cleaned by scraping. When assembling, care should be taken not to seat the insulators too tightly upon the gaskets, but the plugs should endure a pressure of 250 to 300 pounds without leakage at the gaskets. The spark plug points should be scraped or polished bright and set 1/64 inch apart if magneto-ignition and the thickness of a dime worn smooth if battery ignition. The breaker box and distributor of the magneto can be cleaned by blowing out the dust with an automobile tire pump and by wiping with a cloth dampened with gasoline. The distributer or timer should be similarly cleansed.

**Why Clutch Acts Harshly.**—A grabbing action of the cone clutch is occasioned either by the leather facing becoming very dry through use or by wear, causing the rivet heads to protrude above the leather face and come in contact with the metal of the flywheel. A dry clutch can be restored by sponging off the face of the leather with kerosene and applying a dressing of either neats-foot oil or castor oil till the leather again becomes soft and pliable. If the leather facing is worn down to such a point that the heads of the rivets come in contact with the metal cone of the flywheel, the clutch will stick, and to restore the clutch it will be necessary to drive down the rivet heads into the leather so as to clear the cone. Leather facing that has become rough or uneven through wear can be restored by rubbing off the high spots with emery cloth, broken glass, a coarse file, or sand paper, making the surface smooth. A new leather should not be refitted unless you are absolutely certain that the old leather cannot be reclaimed. When new leather is refitted, it is best to take the car to some good repairer and have him purchase a facing from the factory and fit it correctly. After the new leather has been fitted it will take some time for it to fit itself to the cone of the flywheel and in the meantime it will require frequent dressings with either neats-foot or castor oil.



*Left:* S-5 running at the surface. *Right:* Stern of S-5 within which the crew gathered and through which, by cutting the plating, they were rescued

# The Disaster to One of Our Latest Submarines

## How an Air Valve, Inadvertently Left Open, Caused S-5 to Plunge to the Bottom

THE story of the sinking of S-5, one of our latest submarines and of the fight for life, lasting for thirty-seven hours, of the officers and crew, forms one of the most dramatic among the many weird experiences which have befallen various submarines during the past twenty-five years. It is not our purpose here to tell in detail the story of the desperate struggle of the entombed crew to escape. That has been done in very full detail in the daily press by the commanding officer of the vessel, Lieutenant Commander Charles N. Cooke.

The S-5 left Boston on a Monday on a 72-hour endurance run to Baltimore, during which everything functioned satisfactorily. On the following Wednesday she made a "crash dive" at a point 55 miles southeast of the Delaware Capes. The vessel responded to the diving rudders, but failed to straighten out after submergence and dived down until her bow was embedded in the sea bottom. Ultimately by blowing out the main and after tanks, the stern was lifted until the vessel stood in the position shown on the cover of this issue. The crew cut out a small hole through the projecting stern and by means of a brass rod with a sailor's undershirt tied to it, managed to attract attention. Finally, after thirty-seven hours of peril, a hole was cut by the rescuing ships through the hull of the submarine of sufficient size for the rescue of the crew.

It is gratifying to read the following statement in the story of the disaster as given by the Commander: "Next to my inexpressible admiration and praise for every officer and man in my crew and my pride in their courage and fortitude, my deepest feelings are those of gratitude to the officers and crews of the "Alanthus" and the "General Goethals" who so heroically and tirelessly labored to effect our rescue."

With a view to explaining what happened to S-5, we publish an approximate longitudinal section of the vessel, showing in a general way the various compartments and the ballast and trimming tanks, together with the position of the air valves and piping through which the water which sank the vessel found entrance. Successively, the various bulkheads divide the submarine into a forward trimming tank, a torpedo room, crews quarters, central control compartment, engine room, motor room, and after trimming tank. In the lower part of these compartments there are also the forward and after ballast tanks, the main ballast tanks and the fuel tanks, together with the accumulator batteries.

Contrary to popular conception, a submarine spends ninety to ninety-five per cent of its time upon the surface, and navigation, even in war time, takes place on the surface except when enemy ships are in sight or an attack is to be made. When the vessel is submerged, all bulkheads, manholes, et cetera, are tightly closed; but when running on the surface the bulkheads are open throughout the vessel and ventilation is secured by means of a system of air pipes connected with the outside atmosphere and provided with valves where the pipe enters the various compartments. In our sketch, this pipe is shown by a heavy black line. The intake is by means of a vertical pipe terminating outside the hull, in rear of the conning tower, and provided there with a valve, which is operated by means of a hand-wheel and vertical rod from the central control compartment within the hull. The vertical pipe connects with a horizontal air pipe, which is laid along the outside of the hull proper of the submarine and has connections with the torpedo room, the central control compartment, the engine room and the motor room. The passage of the air into the various rooms is controlled by overhead hand-operated valves as shown in the drawing.

When the submarine is running at the surface, these ventilating pipes with their valves are all open and the bulkhead doors connecting the various compartments are also open. Fresh air is drawn into the submarine, passes through its whole length and is ultimately drawn into the engine and discharged through the engine exhaust.

At the time the accident happened, the S-5 was making what is known as a "crash dive." To make this dive the vessel is first brought awash with her ballast tanks filled and with some fifty to one hundred pounds of positive buoyancy. When the order to dive is given a klaxon horn sounds in the various compartments and all doors are closed and all ventilating valves shut down, including the one abaft the conning tower. The oil engine is disconnected and the motors are connected up and started. The diving rudders are then depressed sufficiently to cause the submarine to descend at an angle of about eleven or twelve degrees with the surface. In a crash dive a well-balanced submarine with an expert crew can pass out of sight in from 48 to 52 seconds.

In making the dive off the Delaware Capes everything went according to schedule until Commander Cooke elevated his diving rudders to bring the S-5 to a level keel. Instead of responding, she kept on going, and finally drove her nose into the mud with a jar which was felt throughout the vessel. Immediately a man from the torpedo room ran into the central control compartment and reported that the torpedo compartment was flooding through the air valve. Water also began to come into the engine room, and it was at once evident to Commander Cooke that the ventilating system was more or less open to the sea and that the valve at the top of the conning tower was open. Efforts were made to close the valve in the torpedo room, but without avail. Subsequently, and with much difficulty because of the steep inclination of the vessel, the various bulkheads were closed and the men drawn aft until the whole of the crew were in the three after compartments, the aftermost air valve in the motor room being tightly closed and the room free from water.

The S-5 had gone down in about 155 feet of water, and although her inclination was about sixty degrees, her great length of 231 feet sufficed to bring some

*(Continued on page 312)*

*THE outstanding lessons of the sinking of S-5 are first the imperative need for making up the complement of a submarine crew from the older enlisted men and, secondly, the insistent demand in the submarine service for that eternal vigilance which in this mechanical age is more than ever the price of safety. Before the war, submarine crews were selected from men in their second and third year of enlistment, and it was common to find a crew made up entirely of petty officers. The majority of these experienced men left the Navy for shore jobs that would enable them to live. The younger men of recent enlistment have not yet attained that automatic impulse to do the right thing in an emergency, which comes with lengthy service.*—THE EDITOR.

## Timing the Hundred-Mile-Per-Hour Racer

By Ralph Howard

TIMING meteors or mammoth steel projectiles hurtled through space from America's biggest naval guns should be a task almost as easy as the accurate timing of automobiles speeding around oval race courses or on straightaway speed stretches, especially when Tommy Milton, the newest speed ace, cuts loose in his sixteen-cylinder Duesenberg racer at the rate of 156.047 miles per hour.

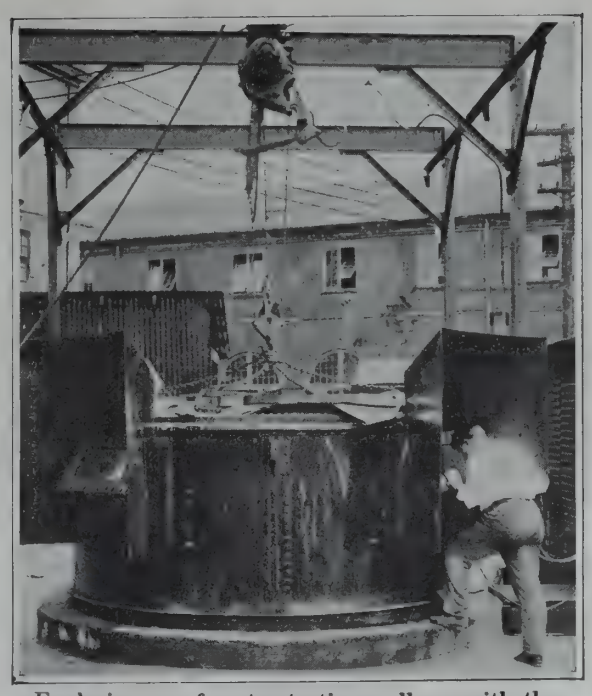
The human eye cannot discern a steel projectile in flight, so rapidly does it travel. And it is almost all the human eye can do to discern distinctly the speeding Milton when he steps on the gas pedals. He usually is just a blur. Experimental time computation tests conducted on a naval coast gun, have shown its 380-pound projectiles to have traveled 17,881 yards in 50.53 seconds. Actual time records show Milton to have traveled a mile in 23.7 seconds or 3752.32 yards in 50.53 seconds, while the projectile was going 17,881 yards. Therefore the steel missile, traveling at the speed of a mile and a fraction under five seconds, went only 4.76 times faster than Milton.

The projectile's speed was computed by measuring the time required for it to pass over a given space. But the time of Tommy Milton's record-breaking speed dash was accurately caught to the hundredth part of a second, the same as the time of every one of the twenty-three racers speeding around the Indianapolis oval recently, was caught on every lap to the hundredth part of a second by means of one of the most remarkable and most sensitively tuned instruments ever conceived in the brain of man.

Catching the time of twenty-three cars, all going at a speed varying from 88 to 93 miles an hour, on every one of 200 laps for each car—a total of 4,600 separate operations for the timing instrument—is not an easy task. It is a particularly difficult task when half a dozen snorting, lurching racing machines sweep past the timing stand in a bunch, for the separate time of every car must be caught accurately, even when there is only five-hundredths of a second's difference in time between the cars.

Otis A. Porter is the man who handles the timing of the Indianapolis speedway races. The timing instrument he uses is an assemblage of delicately tuned electrically corelated mechanical devices, and is so extremely sensitive that it registers in fractions of seconds up to even one two-hundredth part. Upon the precision and accuracy of this intricate machine naturally depends very largely the success and outcome of the race. One second's laying down on the job, one tiny slip-up, and some driver may be robbed of a well-earned victory. One hesitation in the operation of the instrument and the time of a dozen cars thundering down the speedway stretch may be lost, causing subsequent confusion and creating almost a hopeless muddle.

The important mechanism consists of a series of disks, four in number, with raised numerals, each disk graduated. The first disk, registering in hours, is connected with a second disk graduated in sixtieth parts and registering minutes. The third disk, similarly graduated, register seconds, and is connected with a fourth disk graduated in hundredths. The latter is connected electrically with the second hand of a ship chronometer. Every tick of the second hand



**Explosion-proof motor-testing gallery, with the chamber closed and the operator in position for observing results of tests**

sends the wheel around in one complete revolution, and every revolution of the hundredths disk "kicks over" the disk registering seconds. In turn every revolution of the second disk "kicks over" the minute disk one notch. A small steel wire stretched across the speedway course connects with the timing instrument. Whenever a car passes over the wire, the contact through electrical stimulus causes the timing device to record the time. A striking arm above the four disks strikes on a strip of paper, registering the imprint of the numerals on the four disks. The machine recovers from each operation quickly enough to permit another registration with less than five hundredths of a second elapsing. On a machine running 60 miles an hour, it is thus possible to catch the time of both the front and rear wheels as they pass over the wire, the two registrations showing four hundredths of a second difference. But when a car is exceeding 60 miles an hour the rear wheels do not register, the front wheels depressing the wire and the rear wheels whizzing over before the wire can rebound from the first impression.

As each car passes over the wire, an assistant calls out its number, the timer marking this number opposite the time recorded on the paper tape which is shifted forward with each registration. Scorers tabulate the laps made by each car, while the timer's assistants, by subtracting the time of the preceding lap from the last registration made, obtains the lap time and from it tabulates each car's complete lap performance and total time.

When Ralph DePalma qualified for the Speedway races on May 26 he made a new track record, ripping off four laps or ten miles in the total time of six

## Bomb-proof Coal Mining

By S. R. Winters

THE use of electricity in cutting coal is a desirable feature because it is easily adaptable to varying forms of service. However, apparatus heretofore used in fire-damp atmospheres—an explosive mixture of natural gas and air—was of such a character as to render extremely dangerous the use of electricity in mining coal. The recently approved explosion-proof coal-cutting equipment overcomes this major objection, according to claims. The testing outfit was coöperatively designed by the Bureau of Mines and a manufacturer of Columbus, Ohio, the latter constructing and installing the equipment as a gift to the Government.

The explosion chamber of the Bureau's testing outfit is composed of a cylindrical steel tank, the internal diameter being 10 feet and the height 4½ feet. The cylinder is located in an iron channel-ring which is imbedded in a concrete base; the joint between the cylinder and the channel-iron is gas-tight through the agency of a water seal. There are four observation windows, the operator being protected from flames emitting from the top of the chamber by hoods. Canvas curtains are available for darkening the interior, thus facilitating a keener view of the results of the explosion. When the gas has been exploded the pressure is released by oiled-paper heads, which are held in position by iron rings. The bomb-proof gallery when not in use is preserved from the weathering elements by sheet-iron covers.

A fan and circulating system make possible the maintenance of uniform mixture of gas and air in the chamber as well as in the motor and other apparatus under test. The explosive mixture is discharged into the bottom of the chamber at two opposite points, the outlets being six inches from the cylindrical wall and so constituted as to give the gas and air a rotary motion. The gallery atmosphere and the entering gas are mixed in desirable proportions. The main suction line from the fan enters the chamber floor near its center.

Mounted on the switchboard are the controller for operating the crane-hoist motor, the switch mechanism which times the ignition with the release of the indicator drum, and the switch for operating the circulating fan and other circuits connected with the testing gallery. Below the switchboard are chains for opening and closing the valves in the piping connections of the equipment subjected to test. The operator is thus given the opportunity of filling one or more compartments with the gaseous mixture. A 3-ton electric hoist raises and lowers the cover or shifts the equipment in or out of the chamber, and is even capable of lifting the cylinder from the concrete base. Following each test the cover of the testing gallery is elevated to air out the chamber and permit of the entrance of the operator.

## Conservation in De-gumming Silk

IT is claimed that by a recent process raw silk may be de-gummed without the use of soap. It is proposed to treat the silk under pressure with water containing a small quantity of ammonia, borax, caustic soda, soda ash, or other alkali of similar character, for one-half hour. Distilled water is used as the solvent and the pressure employed is seven pounds.

# The Oil-Field Geologist

## How Science Has Made Gambling on Petroleum Prospects a Thing of the Past

By O. R. Geyer

THERE is no more entertaining romance of the oil fields today than that of the oil field scientist, or geologist, whose discoveries have revolutionized the oil industry of the world and who, in the immediate future, will lead the desperate battle to bolster up the production of oil until it can more closely keep pace with the tremendous demand for crude and refined oil products.

Fewer than a dozen years ago the man who professed to be able to discover the location of Nature's secret oil pools without first running the hazardous risk of sinking test wells was about as popular in the oil fields as the fool who plays with matches in the vicinity of a newly tapped gas pocket. Hardened gamblers who had won and lost fortunes by "wildcatting" for oil pools looked upon the geologist with contempt and scorn. This was especially true in the oil fields of the West and Southwest, where the work of geologists in the Appalachian fields was not regarded as a serious contribution to the work of unlocking the vast storehouses of oil so craftily hidden by Dame Nature.

Conditions have changed vastly since those days in which the Mid-Continent field of Kansas and Oklahoma first smashed all records for production. Today the oil field geologist is a highly respected expert, and so great is the demand for his services that there is not enough of him to go around. Schools and colleges which specialize in turning out full-fledged geologists able to cope with the oil game cannot graduate them fast enough these days, and it will be many years before this type of expert becomes a drug upon the market. In fact, the demand for his services will increase in the same ratio as the consumption of oil increases over production.

The conservatism and efficiency of science have long since replaced the methods of the old-time "wildcatter." The oil barons are no longer content with "hit and miss" methods and are paying exceedingly well for the services of men who can reduce to a minimum the dry holes which plague the most resourceful leaders of the industry. The commissions earned by the geologists who have been successful in discovering new oil fields mount into fabulous sums. Many of these experts have long since become millionaires, fees of $500,000 or more belonging to the common, or garden, variety.

*HOW many of those discriminating investors who try to separate the sheep from the goats when they turn to oil stocks for investment realize that they are here backing science to unlock the secrets of Nature's storehouse of liquid gold? How many of them understand the revolution in methods which has come over the oil fields in the past ten years? No longer does the "wild-catter" flourish, the man who drilled for oil because he had a lucky "hunch," or because he thought maybe oil was there. Today the geologist precedes the driller, and while he cannot show a clean score of successful predictions, he has vastly reduced the hazard of unprofitable boring. How he has achieved this and what his success means to the industry are the theme of the present story.*—THE EDITOR.

The discovery of the Ranger, Burkburnett and Homer pools in the Southwest can be attributed in no small measure to the work of some of the best known oil geologists in the country. The Ranger and Burkburnett fields had scarcely been converted into "proven" territory before these experts were dashing out to all corners of the world in their frantic search for new oil pools. Today there is scarcely a nation in the world which cannot boast of the presence of one or more of these experts engaged in mapping out likely fields for the work of the prospector. Because of the ever-increasing inroads being made upon the reserve supply of oil, this search is approaching the stage of desperation. Even now experts are hinting broadly that the undeveloped oil fields can scarcely supply the world's needs for more than another quarter of a century.

Fuel oil has been substituted for coal as the motive power for hundreds of steamships, and this, too, has contributed to the enormous drain being made upon the country's reserve supplies of crude oil. A year ago it was estimated that the country's oil fields would have to increase their production by 50,000,000 barrels a year to prevent further inroads into the reserve supply. The demand for crude oil and its products has increased enormously since then, making it necessary for an even greater increase in production in case supply and demand are to be kept on even terms.

Hence the importance of the geologist. Thousands of these experts are combing the world today for possible oil "structures." Alaska, Canada, Mexico, Colombia, Venezuela, Brazil, Trinidad, Cuba, Russia, Rumania, Alsace-Lorraine, Germany, Great Britain, France, and various parts of Asia and Africa today are under the watchful eyes of oil geologists. Hundreds of millions of dollars must be expended in this work of prospecting and sinking test wells in all corners of the world, and there are billions awaiting those who are successful in the prosecution of this world-wide game of hide-and-seek with Dame Nature.

There is scarcely a paying field in Oklahoma or the Southwest whose location was not known definitely to geologists long before the drill began pounding its way into the bosom of the earth. Notwithstanding the excellent record established by science in locating oil pools, it is by no means perfect as yet. In proven territory it comes very close to a 100 per cent score, because in such cases the problem is not to locate new pools but to find the most advantageous point for the sinking of new wells.

Many of the larger and more conservative companies have drilling records of from 75 to 90 per cent in the way of successful producers, although many of these wells have been sunk in more or less unproven territory. Geology has done this, of course, and as experience multiplies there is no reason why this record should not be improved. The importance of advance knowledge of the location of oil pools will readily be understood when one appreciates the high cost of drilling these days. In Texas, where the oil sands are located from 2,000 to 4,000 feet beneath the earth's surface, an ordinary well costs from $25,000 to $50,000, and failures are exceedingly trying upon the pocketbook, especially in the case of the shoestring operator.

The remarkable results obtained by some of the best known geologists in picking out likely locations for wells and in casting out the bad spots would fill a book. The success enjoyed by one Sullivan, the geologist who mapped out the immensely prolific Burkburnett pool, is only one of the striking examples of the proper procedure in the exploitation of new oil fields.

Two years ago, when the rumbles of the approaching oil discoveries that were to startle all the world were heard in Texas, Sullivan was sent into what is now known as the Burkburnett district to prospect for likely oil pools. He studied this field exhaustively for miles in all directions, and mapped out what appeared to him every spot that could be drilled successfully as well as probable duster territory. Since that time hundreds of wells have been drilled in this territory, and so carefully did Sullivan select the sheep from the goats that oil men generally have scored him as a 100 per cent geologist.

The work of the geologist is based upon the anticline theory perfected in recent years. An anticline, one finds on consulting Webster, is "a fold or arch of rock strata dipping in opposite directions from an axis." Oil wells are drilled on these anticlines, commonly called drilling on "dome" or "structure." Geologists have found that the rock and sand strata in anticlines formed by the earth's convulsions are more productive of oil and gas than any other earth formation, and this has made the work of the prospector much easier than in the days of "wildcatting."

In beginning his work the geologist first seeks to find an unbroken fold or anticline of rock. He knows that in the pocket thus formed by nature he may find a pool of oil. This is by no means certain, however, for any number of things may have contributed to the lack of oil. The first and most probable is that a concealed break, hundreds of feet below the surface, may have allowed the gas and oil stored there to escape hundreds or thousands of years ago. The pool might have been formed as the result of one upheaval of rock, only to be drained by a second shock coming centuries later. Earthquakes, for instance, have a sly habit of wrecking profitable oil fields by opening up new cracks and crevices hundreds of feet down in the earth and allowing the oil to escape into new pockets and pools. The skill of the geologist is of little avail in locating these hidden mysteries.

Three important factors enter into the accumulation of gas or oil beneath the earth's surface, geologists have discovered. The first is a favorable structure—anticline or monocline. The second is a good open sand, and the third the right height of structure with reference to salt water. Of these three factors only the first can be determined more or less definitely before drilling, and there is always the chance that a freakish twist or convulsion of nature has destroyed the "scent" followed by the scientist.

The development of oil field geological research dates back to the time of Dr. I. C. White, who surveyed what are known as the West Virginia, or Appalachian, fields. His reports on oil "structures" in that field have formed to a large extent the basis for investigations in all other fields. Later other pioneers took up this work in Pennsylvania and Illinois, but the Mid-Continent fields had become the country's principal producing district before this science had gained a foothold in the Southwest. Almost all of the discoveries which made Oklahoma the greatest oil producing State for a time were the result of geological investigation. The Cushing field, which will go down into history as the world's greatest oil pool unless some new record breaking discovery remains to be made, was brought in at the insistence of geologists.

Since those pioneer days commercial geologists have been turned out in large numbers to meet the demands of the oil barons of the South and Southwest. A short course for oil field geologists, patterned after the short course idea which revolutionized farming methods in the Middle West, was established some years ago by an Oklahoma college as a means of overcoming the shortage of geologists. Since then the student roll of every college specializing in this work has been carefully scanned by the great oil companies for any possible additions to their staffs.

The rewards paid geologists who have made a success of their work in the Southwest make them the country's highest paid scientists. Fees received by some of these experts have been enormous, and it is a poor geologist indeed who cannot command a salary well up in four or five figures. Oklahomans are fond of telling of the two Vandruffs, father and son, who stopped off in the Oklahoma fields at the invitation of one of the oil companies. The president of this concern was anxious to discover a new field which would enable his company to maintain its rate of production far into the future. The two experts, who had originally intended to locate in California, were sent into the wilds of a rough and hilly section of the State which had been scorned heretofore by oil men.

They spent weeks making a minute examination of the rock formations, and as rapidly as their work was completed lease men employed by the company followed them up, signing up all approved property at moderate sums. When the Vandruffs completed their investigations, this company had obtained leases on 6,000 acres of property which had been scorned by more conservative oil men. As their fee, the father and son received a one-eighth interest in the property. Some months later the first well was brought in and a prolific producing pool worth many millions of dollars had been revealed. The two disposed of their interest for $500,000, a princely sum in those days.

The rewards to be gained by oil field geologists have been by no means exhausted, and will continue to mount and grow as prospectors continue their one-sided game of hide-and-seek with Dame Nature. At the present rate of consumption America must increase her production of crude oil at the rate of more than 40,000,000 barrels a year if she is to keep pace with her own needs. In 1919 more than 400,000,000 barrels of oil were required to meet domestic needs.

## Improvements in Screw Measuring Machines

DR. P. E. SHAW, of University College, Nottingham, England, has further improved his screw-measuring machine, which has already been mentioned in these columns. The new machine appears to be very simple in construction and rapid in operation. All the movements are sliding, thus greatly reducing the time needed as compared with the tedious manipulation of the ordinary micrometer devices. One special merit claimed for the new machine is that it is equally applicable to plug and ring screws. There appears no reason to doubt that this claim is correct, in which case a distinct advance in meterology will have been secured, as the present method of measuring ring screws by means of standard plugs is not only tedious but requires a costly outlay for apparatus. The accuracy of the new machine is stated to be to 1-5,000th of an inch on diameters, and 1-20,000 on pitches, both in the case of plug and ring screws, thus satisfying the highest requirements of ordinary practice.

## Chemistry Applied to Safety

THE National Safety Council is responsible for an investigation undertaken at the Bureau of Standards to determine the action of hydrochloric acid on manila rope. When brick work is washed down, the commercial grade of hydrochloric acid known as muriatic acid is commonly employed, the men working from staging supported by manila rope used in blocks and falls. Accidents have occurred because of the rope becoming weakened through contact with the acid or its fumes, and the action takes place without any superficial trace being noticeable to the eye. Serious accidents have resulted, hence it is now suggested that the rope be treated with some acid-resisting compound. This portion of the investigation is now under way, especially with reference to ascertaining the protection which would be afforded the rope by the use of compounds which have proven effective in protecting machinery and similar equipment from acid corrosion.

## Purifying Oil by Centrifugal Action

FOR many years there has been in use in most of the large engineering works of this country a centrifugal separating machine which removes the oil from iron and steel turnings or borings, and thus permits it to be used over again. The idea which underlies this machine has now been carried further and applied to the removal of the dust and dirt which unavoidably collect in oil used in the lubricating systems of marine and other large engines. The new machine is very similar in form and operates on the same principle as the now well-known centrifugal cream separator. The foul oil is fed continuously into the machine through a strainer which catches any gross particles, precisely as milk is fed into the cream separator. The purified oil escapes continuously, while the dust and dirt collect on the inner surface of the separating drum. Provision is made by which the attendant can instantly tell when the machine is choked with the deposited impurities.

## Rotatable Coal Hopper for Locomotives

FIREMEN on big locomotives find promise of lightened work in the rotatable coal hopper that has been invented for engine tenders. This invention is so planned that the coal is kept handy at the firing deck, making it an easy matter for the firemen to reach the coal without shoveling from the rear of the tender or using power apparatus. This special hopper is in the form of a great segmental tub, or drum, having a diameter that is the approximate width of the tender. This drum is inclined toward the firing deck; it is so mounted on a ball-bearing center plate as to turn readily. In its outer wall are openings, one for each segment, through which the coal falls by gravity. As soon as the coal is emptied from the segment, the brake that controls the drum is released. Naturally the greater weight above the center of the drum makes it rotate, bringing the next loaded segment into position.

## Hunting the Dinosaur Fossils

ALBERTA was the home of many terrible reptiles and mammals now known only by polysyllabic names according to W. E. Cutler, who is excavating in the Red Deer valley for prehistoric remains. He has been digging up the skeleton of a Ceratopsian (Horned Dinosaur), and has located the whole of one side and the skull. He has also obtained a fine skull of the Stereocephalus Tetus (the Armored Dinosaur), with massive plates of bone imbedded in the skin, some of the plates being an inch in thickness. Recently too he found the fossilized skeleton of a Hadrosaur or duck-billed dinosaur.

Two dinosaur beds are located in Alberta, the Edmonton beds of the later period on the Upper Red Deer River near Drumheller, the coal town, and the Belly River beds commencing at Steveville and extending twenty miles downstream on the Red Deer. The species—although a few are common to both beds—are separated by a layer of 800 feet of marine deposits which contain remains of marine creatures.

In those early days figs grew in Alberta but the land area in western Canada was small, a central ocean dividing the solid earth from the Peace River to Central America with a coast line near Field and Banff and high mountainous country to the west. Mr. Cutler believes that the silt in which the prehistoric monsters' remains are found came from this mountainous district.

He reports that it is becoming increasingly difficult to get good specimens and he advises Alberta to get some and store them until it has the proper facilities to display them. At the same time he thinks it would be a mistake to place an embargo on the export of specimens by Barnum Brown and other American explorers.

## Zinc Manganese Alloy

IT is claimed that a satisfactory substitute for copper, bronze, and brass has been devised by adding not more than four per cent of manganese to zinc. The resulting metal is claimed to be about twice as hard as zinc and to have far greater resistance to impact. It is said to be possible to forge the new alloy when warm and also to stamp and roll it.

## Research Scores

A LARGE body of ore discovered during development work in search of gold-bearing material was found to yield about $3 worth of gold and silver per ton, which, notwithstanding a low cost for concentration, was entirely unattractive. The problem was put before a group of research men who have found that besides recovering the precious metals the material can be made to yield per ton $20 worth of white sulfur and another $20 worth of paint pigment, for both of which products there is an active demand within a reasonable freight distance. The cost of the entire operation is such that more than $35 net per ton can be realized from a material that a few years ago would have been discarded as not worth working.

## Sound Records

A PROCESS for producing sound records has been patented in which a fine modeling clay is substituted for the usual wax base materials employed for recording sounds. When the record is made the clay is dried so that the exact character of impression made by the recording needle is retained. The disk is then fired in a pottery kiln and a metal matrix from which records for sale are made in the usual manner, is prepared from this pottery disk. It is also claimed that plaster of Paris or other cement just about to set may be employed.

## Japan as a Buyer of Copper

ONE of the surprises of the year just past has been the rôle played by the Japanese in the American copper market. On every recession in values, buying by such interests has been an important factor and comment as to the object behind it has been general. The magnitude of this annual movement may be appreciated by the fact that last September the copper exports to Japan were nearly 60 times what they were in the ten years ended with December 31, 1918, while for the ten months ended with October, 1919, Japan is credited with 63,100,000 pounds or over 140 times as much as for the ten-year period referred to. Japanese buying of zinc, while not so striking as in copper, has also been heavy.

In other years Japan has exported about half of her own copper output. It is therefore surprising that she should have made such a complete reversal of policy. This may be partly explained by the statement that Japan's production of copper has decreased and her consumption increased. But there is something more than this.

Japanese manufacturers and laborers have learned how to produce in mass and the country has undoubtedly started on an era of great industrial expansion. One view of the situation is that because Japan had a thorough training in munition work, this expansion is making its first appearance in brass making. Japanese merchants are said to have discovered that Germany had prior to the war an extensive export trade to the Far East and to South America. To capture this may be one explanation of the recent buying of copper.

Whether or not, as not a few think, this heavy buying of metals and other materials portend the existence of a Germany of the Far East, it is certain that it means that Japan with her cheap labor and great imitative power, will be or already is a most important factor in the world's international trade.

## A Marsupial Rhinoceros

AS the result of an examination of a nearly complete skeleton of the extinct marsupial Nototherium Mitchelli, hitherto known only from fragmentary remains, found near Smithton (Tasmania) this year, Messrs. H. H. Scott and Clive Lord have come to the conclusion that the Nototherium was a marsupial rhinoceros. The structure and shape of the horn are matters for conjecture as no remains of it have been found but the specially constructed cervical vertebrae, the structure of the nasal regions and the curious nasal cartilage—all point to the conclusion that the animal possessed a rhinoceros-like horn. If so it is a curious case of parallel evolution for the true rhinoceros belongs to a different and "higher" group than the marsupials, none of which at the present day possesses anything remotely resembling horns, nasal or otherwise.

## Tuna Fish Oil

ACCORDING to a circular issued by the Paint Manufacturers Association excellent results have been obtained with tuna fish oil indicating that this product can be utilized, in whatever quantity produced, by the paint industry. Comparative drying tests have shown that tuna fish oil dries more rapidly than most grades of raw linseed oil. The gravity, iodine number and saponification value of the oil are similar to the constants of linseed oil, while the high iodine value, 184, is of unusual interest since it is actually higher than that of most linseed oils.

Yellow tail fish oil is another product supplied by the Bureau of Fisheries for these tests. It gives results almost as satisfactory as linseed oil.

## Improvement in Cement Manufacture

A UNITED STATES patent has been granted covering what is claimed to be an improvement in the wet process for manufacturing Portland cement. It frequently happens that the slurry sets to such an extent as to prevent its efficient handling in the usual apparatus. The object of the invention is to provide a setting preventive which will facilitate the use of the wet process and subsequently be destroyed in the kiln. One quarter of one per cent of sugar has been found satisfactory, since it prevents setting in the slurry and is of course eliminated during the clinker operation. Molasses, oxyacids, oxy-aldehydes, and oxy-ketones are examples of other suitable materials.

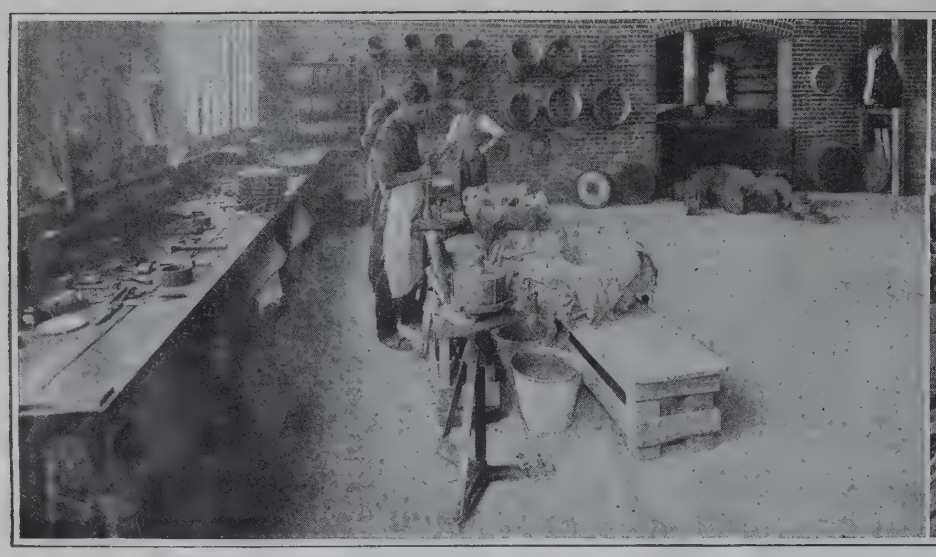
## American Potash

IT may be well to again remind those who have looked forward to the purchase of cheap German materials that times have changed throughout the world. German potash is now being quoted to the German farmer at from $2.70 to $3 per unit for the same material which formerly was sold to the American farmer, transportation paid, at 60 cents per unit wholesale. Now, on this basis the American bill for German potash used in agriculture, calculated on the imports of ten years ago, would be 75 millions in place of 15 millions as formerly.

In view of these facts, we should be very slow in discarding the beginnings that have been made toward supplying potash to American farmers from American sources. As it is now, the American industry has been discouraged and under the conditions prevailing abroad we can expect little from the old sources for some time to come. The situation as it now is was outlined by J. W. Turrentine during the recent meeting of the American Chemical Society.

## Raising a Train Shed

THE Delaware, Lackawanna & Western Railroad has nearly completed a project of raising to its original level its Hoboken, N. J., station train shed, the supporting columns of which had sunk irregularly from 5 to as much as 14 or 17 inches in places. This shed is the first ever built of the Bush type with slots for the locomotive smoke stacks. It is 360 feet wide and 630 feet long, covers 14 tracks and an area of about 5 acres and weighs 18,000,000 pounds. It is supported on 207 cast steel columns each set on a concrete foundation resting on 80-foot wooden piles which had settled. The shed was raised in 4 sections by means of jacks at each column in the station to bring the roof to its proper level. The concrete platforms have also been built up and the tracks raised to their original level. The old scheme of wire-glass roofing with large sections of glass which used to break from the vibration has been replaced by a concrete and vault light roofing. The whole project has been carried out without delay to a traffic of 225 trains daily or without inconvenience to the 1,500,000 passengers who use the station monthly.



Making silicate grinding wheels

Finishing room where wheels are trued up

# The Toolmaker's Tools

## The Modern Art of Grinding, and How the Wheels That It Uses are Made

By W. F. Sutherland

WHEN man first learned the art of working bronze and later iron he no doubt cast around for some suitable stone on which to give the finished tool or weapon a keener edge. Later on after the invention of the wheel and axle the fashioning of a gritty stone to a circular shape and its mounting on a circular axle came as a matter of course, but while other mechanical processes have undergone continual change and betterment the art of grinding has remained, until a few short years ago, much the same throughout the ages.

Today precision grinding is perhaps the most important machine shop process, for without it the automobile, the airplane engine and countless other standardized mechanisms would be impossible. Together with the accuracy possible with the modern grinding machine goes the usefulness in general of the abrasive wheel for rougher operations and in the combination of these two functions is found an instrument, without which modern industry would almost cease to function.

This is all the more remarkable since it can be safely said that modern grinding practice is hardly more than twenty-five years old. The modern abrasive wheel has kept pace with the development of grinding machinery and the increasing number of fields in which grinding finds a high degree of usefulness. The development of artificial abrasives and the care now used in incorporating them into the finished wheel have given the user a wide range of wheels with which he can grind anything from rubber to the hardest steel.

Aside from the natural grit stones found in every part of the world, emery has perhaps been in use for the longest time. Emery occurs as a granular or massive dark colored rock having much the same appearance as iron ore. It is usually associated with the oxides of iron and in addition to these sometimes contains quartz, mica, tourmaline, etc. Indeed emery may be regarded as a rock rather than a definite mineral species.

The chief sources of emery are found in the old world, the island of Naxos having important deposits which have been worked from a remote period. Turkey contains large deposits and the island of Madagascar also has some emery. Emery is also found in several localities in the United States.

Emery is only a very impure form of corundum, a mineral composed of alumina ($Al_2O_3$) and which forms in some of its finer varieties valuable gem stones. The finely colored transparent varieties include such varieties as the ruby and sapphire, while the impurer and granular forms are known as emery. The term corundum is now more or less restricted to the remaining varieties which while they have a crystalline structure are not of value for ornamental purposes through their poor appearance.

It is these latter varieties which make a valuable abrasive and corundum, under various trade names, forms the basic material of one large branch of abrasive wheel manufacture. The corundum used is either mined or produced artificially in the electric furnace, the latter becoming more and more the source of supply.

The largest deposits of natural corundum as distinct from emery are found in the province of Ontario. Three distinct outcrops have been observed, one of them being about 103 miles long by about 6 miles wide at its widest point. The corundum is found scattered through the rock in the form of six-sided prisms, sometimes of considerable size.

While alumina is generally conceded to be the third most important constituent of the earth's crust, being only outclassed by silica and oxygen, its occurrence in crystalline form is not so widespread as one might suppose. Corundum however is by no means a rare mineral, recent explorations and examinations having revealed important areas of corundum-bearing rocks throughout the world.

It is generally conceded that man cannot equal Nature's handiwork in many particulars, such as painting the lily, but while this is true it is given to him to rival her in other respects. Such is the case when it comes to abrasives, and not only is it possible to produce artificially a corundum having more desirable properties than the natural but it is also possible to produce another abrasive of an entirely different nature not found anywhere in a natural state. This latter product is carborundum, a compound of carbon and silicon. Both the artificial corundum and carborundum are produced by the same means in the electric furnace.

In the making of artificial corundum, bauxite ore is used, the same substance from which aluminum is won, but of slightly lower alumina content. In appearance not unlike ordinary clay, it differs from it in the much higher content of alumina present, that used for abrasive manufacture having a representative analysis of about as follows: alumina, 55 per cent; silica, 8 per cent; ferric oxide, 4 per cent; and titanium oxide, 1½ per cent. The bauxite used in the manufacture of abrasives at Niagara Falls is obtained in Georgia, Alabama, Arkansas and Tennessee. Large deposits are also found in France and British Guiana.

The major portion of the bauxite used in American industries comes from Little Rock, Arkansas, where open pit mining is carried on and steam shovels load the material into cars for transportation or calcining. As bauxite contains combined water, this has to be driven off before it can be used for aluminum or abrasive manufacture. The aluminum companies calcine the ore before shipment while it is the practice of the other companies to calcine at the furnace plant.

All the companies manufacturing aluminous abrasives have their furnace plants located within a few miles of Niagara Falls on either the Canadian or American side. Cheap power in large quantities is a necessity for electrothermic work and the advantage of the Niagara District in this respect is clearly shown by the number and variety of the industries located there.

While the use of the electric furnace in the production of corundum is necessitated primarily to crystallize the alumina, it also performs certain other functions and enables chemical reactions to be carried on which free the raw material from the silica and other impurities present.

It will be noticed from the analysis given above that considerable silica with some iron and titanium oxides are present in the crude bauxite. Since the product desired is crystalline alumina, these must be removed and for this purpose coke and iron borings are added to the calcined bauxite before it is furnaced. In the reactions which take place, the silica, together with any iron and titanium oxides which are present, is reduced and forms an alloy with the iron which has been added. The result is ferro-silicon of about 11 to 20 per cent grade and this is a valuable by-product, especially so during the period of the war.

The kilns in which vitrified wheels are fired

Pit-type furnaces are used as will be seen from the accompanying illustrations. The furnace consists of a refractory bottom and the four side walls of brick, mounted on a steel truck. These sides never come into contact with the molten alumina, as it is so refractory that it forms its own furnace lining. The carbon electrodes hung on supporting gear are moved up and down automatically by electric control in such a manner as to keep the current which flows through them and the bath at a proper value.

The charge is fed in gradually and at the end of about 30 hours' operation the furnace is full of an intensely hot fluid mass. The alumina floats on top while

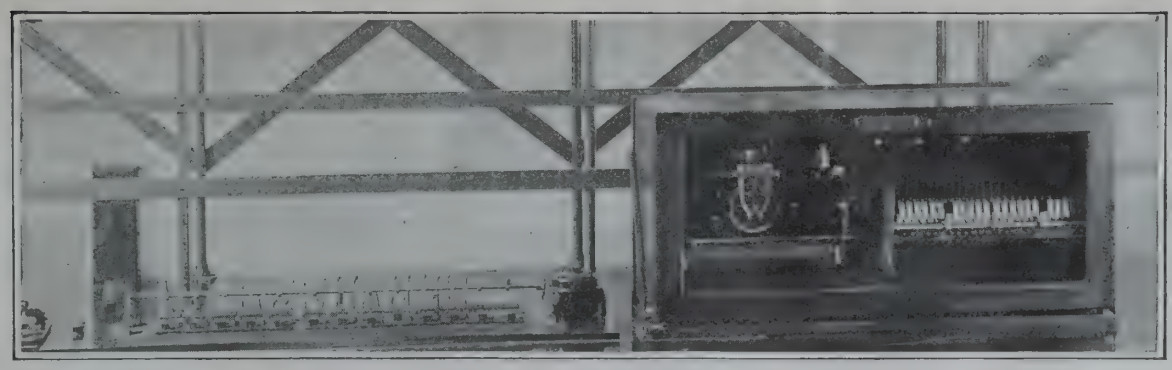
## Gas Control by Machine

AN extremely sensitive apparatus for the automatic control of the nitrate plant at Muscle Shoals, Alabama, has been developed by the Bureau of Standards. The principle of operation is radically different from the workings of former mechanisms designed for similar uses, inasmuch as a single unit has never before been applied to so wide a variety of gas mixtures.



**The wires shown at the left, together with the recording device at the right, analyze and record twelve different gases at intervals of one minute without attention**

The device has the capacity of recording twelve different analyses successively at intervals of one minute, repeating the cycle automatically. It can determine the analysis of carbon monoxide, hydrogen, nitrogen, carbon dioxide, ammonia and various other gas mixtures. Seven different combinations can be unlocked by this apparatus, including interpretation of flue gases, mine oil, blast-furnace gases, and many industrial gases.

The operation of the instrument depends upon the conductivity of heat through the gases. The wires stretched in the axis of tubes placed in the thermostat are heated electrically. The temperature contained by such a wire depends upon the heat conductivity of the gas, which varies with the composition of the gas. By comparing the electrical resistance of two such wires, exposed to different gases, the composition of several classes of gas mixtures can be revealed. This comparison is made automatically by means of the recording wheatstone bridge shown at the right of the photograph.

The unwieldy frame shown in the accompanying illustration is not essentially a part of the automatic gas analysis apparatus itself, the framework being originally planned to support some auxiliary equipment which is not an integral part of the particular machine being discussed. The outfit can be conveyed from one part of the laboratory to another by a single individual. Similar mechanisms are to be installed in the helium plants at Petrolia, Texas, and at the hydrogen plant, Langley Field, Virginia.

## How Uncle Sam Liquefies Hydrogen and Then Bottles It

IF the seemingly extravagant claim of an Italian scientist, that one gallon of liquid hydrogen is sufficient to propel an automobile for 250 miles is borne out in practice, hydrogen liquefiers may become of common usage in the not remote future. As it is, however, the Low Temperature Section of the National Bureau of Standards has designed and installed the first hydrogen liquefier in service in the United States.

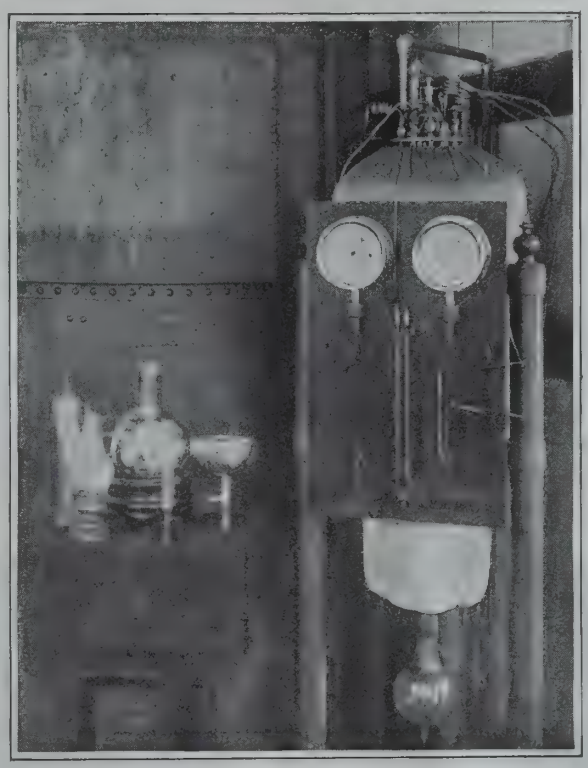
The apparatus, shown at the right in the foreground of the accompanying illustration, admits hydrogen at a pressure up to 2,500 pounds to the square inch. First, it is cooled by liquid air at atmospheric pressure, say, a temperature of approximately 190 degrees Centigrade; then by liquid air at reduced pressure, which produces a lower temperature, and ultimately by its own expansion through a valve. According to this fashion, the boiling point (252.6 degrees Centigrade) is obtained, a portion of the hydrogen is transformed into a liquid state, and is collected in the Dewar vessel located at the bottom of the liquefier.

The cold hydrogen, not converted into a liquid, serves the purpose of cooling the incoming compressed gas, and then returning to the gas holder. Liquid air used for this purpose is produced by the expansion of compressed air within the same apparatus. Solid hydrogen is manufactured by cooling liquid hydrogen, being evaporated under reduced pressure.

Situated on a stand at the left in the photograph is a group of Dewar vessels for holding liquefied gases. The glass containers have two or more walls with the space between highly evacuated as a way of minimizing air conduction, and are usually silvered to diminish the transfer of heat by radiation. The apparatus, in toto, lends speculative interest to the announced discovery of the chemist in Italy, who claims to have found a method of cheaply producing liquid hydrogen.

## Improvements in Cast Iron Wheels

FOR the railroad-material industry, the Bureau of Standards has worked out a number of important problems. It has completed an investigation of the graphitization of white cast iron upon annealing. This problem arose in connection with other investigations of the properties and characteristics of chilled-iron car wheels and in particular the best range of annealing temperatures. This was brought to the attention of the Bureau by one of the car-wheel manufacturers. The



**Hydrogen liquefying device at right and collection of Dewar containers at the left**

composition is so chosen and the wheel is so cast that the tread and inside of the flange show white iron and the remainder graphitized or gray iron. In order to relieve the stresses set up during the cooling of the wheel under drastic conditions, the wheels are piled in pits while red hot and allowed to cool very slowly. Investigation developed that the highest temperature at which no graphitization of the tread and flanges takes place is about 700 degrees Centigrade, which is also the maximum annealing temperature for car wheels.

The investigation of stresses in chilled-iron car wheels caused by heat from brake action has been nearly completed, says the Bureau report. A very large percentage of car-wheel failures are attributed to stresses caused by heating of the tread by brake action, the central part or hub of the wheel remaining relatively cool. It is the purpose of the investigation to determine and record for adoption the most suitable material and design of wheels to resist stresses of this kind. In this investigation the tread of the wheel is heated by passing an electric current through a circular resistor insulated from the tread. The wheel remains stationary, thus readily permitting the taking of the temperature and strain-gage readings. Considerable differences have been found in the behavior of wheels differing in design and weight.

## Technical Sponges

A SPONGE can be briefly defined as the skeleton of certain aquatic animals—naturally there are a number of varieties. This skeleton while being fairly strong when first used, gradually softens and breaks down through use and bacterial action. A patent for a tanning process has recently been issued to W. H. Allen of Detroit whereby the strength of the sponge is greatly increased and also increased resistance to bacterial action. The sponge is chemically in the same class of material as hides. It is to be inferred there is a good fortune for the tanned sponge.

## Domestic Hot Water by Electricity

A SYSTEM of domestic hot water supply by electricity, introduced by a British electric company, depends on the use of a tank with an electrical heating device which is kept always in circuit. As the consumption of current by each size of tank is known and constant, there is no need for a separate meter, and on the assumption that the electricity supply undertakings will grant a special low rate for the heating current the amount payable can be found by subtracting this known consumption from the total shown by the meter, the residue being charged at the ordinary lighting rate. The smallest sized tank made takes 150 watts (328 units per quarter of 13 weeks), and is designed to give a daily supply of 10 gallons of water at 150 degrees Fahrenheit, which is reckoned to be sufficient for the domestic needs, apart from baths, of a household of five. For baths it is suggested that the bath room tanks should be fitted with a supplementary heater, to be switched on when extra baths are required, the current it consumes being paid for at the lighting rate. The company disputes the statement that electricity cannot be used economically to heat water, as compared with coal, coke, or gas; it asserts that it is true only in the case of small vessels or a pipe system having large surface area in proportion to cubic capacity, and not in the least true in the case of a large cylinder so designed as to have minimum surface area and a continuous operating temperature well below the boiling point.

## What Is the Lamp's Candle-power?

THE double precision photometer shown in the accompanying illustration is used by the U. S. Bureau of Standards in keeping check with the international candle as maintained by incandescent lamp standards. The apparatus is the final judge for lamps used by the various Government departments as well as private interests that may apply such standards of quality.

Two observers operate the instrument, the lamp stationed upright in the middle of the apparatus being the basis for applied measurement. Simultaneous observations are taken by the two observers with the test lamps. Electrical instruments and adjusting resistances are shown on the bench at the right of the photograph. Records are stamped electrically on the recording drums, one of which is shown at the center of the illustration.

**The Bureau of Standards determines the candlepower of electric lamps by means of this double precision photometer**

# Solving the Labor Problem—I

## The Development of an Industrial Policy of Mutual Interest Between Employer and Employee

By George M. Verity, President, American Rolling Mill Company

*WITH all the strikes and other disturbances involving those who own and those who use the means of production, it is evident that we are living in an age of industrial readjustment. At the same time, in spite of the conflict between apparently irreconcilable extremes, it is beginning to look as though we were really making progress toward a definite solution. It is of the greatest importance in such a time as this to have it forcefully brought home to us that adjustment of the contradictory demands of capital and labor is possible, that it does not necessarily involve either sacrifice of the general outlines of the present capitalistic system or on the other hand a continuation of the unreasoned subservience of labor's interests to capital's whims—in short, that at the present time and in many places a middle ground has been found and a process worked out whereby capital and labor can really work side by side in harmony and good understanding. The* SCIENTIFIC AMERICAN, *in order to contribute to the circulation of this idea, has asked high executives, in plants where cordial relations between the owners and the workers prevail, to write their own stories of how these relations have been brought about. Mr. Verity's story is the first of a series which will include articles by numerous other gentlemen of similar standing to his, the general tenor of which will be to show that the two branches of the industrial community really can live in the same house. We think that this series will be found to contain documents of real human interest, and of very material value in the promulgation of right ideas on the industrial situation.*—THE EDITOR.

IN the early days of the steel industry in the United States and leading up to some twenty-five years ago, there seemed to be an almost universal spirit of suspicion and distrust existing between the workers and mill owners. Young men grew up in the belief that the employer could not be trusted and that any holding out of the olive branch was simply camouflage for selfishness or treachery of some kind or other.

It was the policy of the mill owner (there were more individual owners who were operators in those days than now) to hire and fire as he chose and to look on the worker generally as unreliable and untrustworthy. Coöperation in industry had not as yet been born.

That condition existed to a greater or less degree when The American Rolling Mill Company of Middletown, Ohio, began the construction of its works in the spring of 1900. Actual production was begun in the spring of 1901 with a force of some four hundred men composed of both skilled and unskilled men of the various kinds needed in the several departments of the business as then organized.

From the very beginning, the Management was impressed with the idea that real permanent success could only be attained through the hearty coöperation of all those composing the Company's working organization, that the development of the human element was the key to stability and progress. They believed that such coöperation could be secured through,

First: the adoption and the announcement of a "square deal policy," born of real mutual interest and of a desire to be fair, frank and considerate each of the needs and wishes of the other.

Second: through winning the good will and confidence of our men by consistent support of every policy announced.

Third: through visualizing to our organization from month to month the value and soundness of our policies.

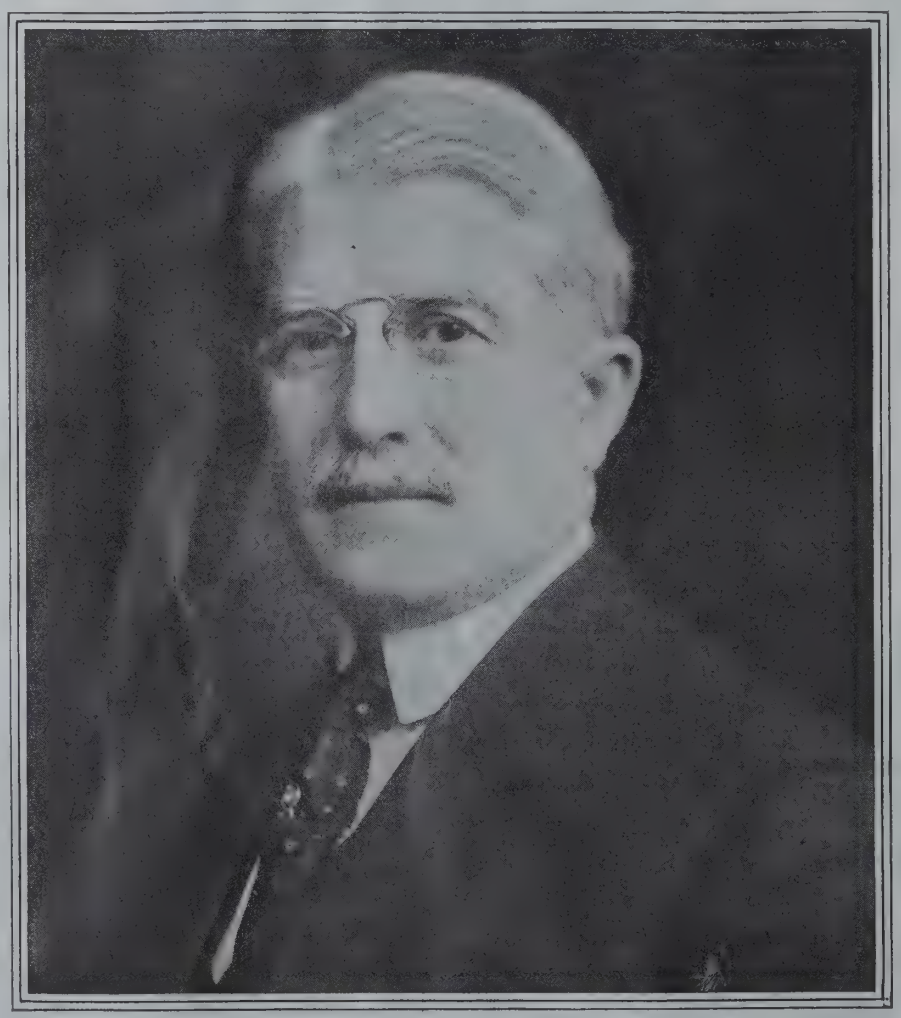
Fourth: through the realization of the fact that a Management must make good to its men just as the men must, individually and collectively, make good to their Company.

Those policies were patiently and consistently supported for a period of five years before we felt that we were entitled to any verdict from our men. At the end of that period we had substantial evidence of appreciation of the policies inaugurated, which gave us courage to make a still greater effort to win the entire confidence of our organization.

An Advisory Committee was appointed by the men in our Sheet Mill Department, which at that time comprised our largest group of workers. Any agreements or suggestions on the part of the men or the Management were put up to them for discussion and consideration. They handled all matters that came before them with such impartiality and fairness that a still closer relation was established between the men and the Management.

At the end of the first ten years, the Company found it necessary to double the capacity of their works and, in so doing, a change from small-mill practice to modern big-mill practice had to be made. This brought in a large influx of new men from all over the country, men who were unfamiliar with our policies and methods of operation. The old organization suddenly became a small part of the new and so it was necessary for us to begin all over again.

While we felt that we had in a very large degree earned the confidence, the good will, and the support of our first group of men, their very belief in the Company was for a time a handicap rather than a help, as the new men felt that they must have been unduly influenced in some manner or other. This new situation, therefore, had to be handled more carefully and wisely than ever as our common interests had become much larger. But a patient, persistent application of our ideas of "a square deal," together with the substantial return that came to the men from month to month and year to year through steady operation without friction or discord, soon had its effect.



**George M. Verity, one of the men who have shown that the interests of capital and labor are not necessarily antagonistic; that these two elements can "live in the same house"**

As the new men came into the light, they began to see why the older men were friends of their Company and a further lapse of time brought them to a fuller realization of the undisputable fact that the Management and men have much in common and that by working together earnestly, diligently and efficiently more could be accomplished for all concerned than could possibly be secured under any plan of suspicion, discord, and contention.

We endeavored to show our appreciation of the good will and the confidence given us by our working organization by expanding and developing our mutual interest policies whenever and wherever possible, through providing everything we could in the way of incentive, of opportunity for progress, and in the doing of anything and everything that we could that might make life and a place in our organization worth while. "Armco" fosters no welfare work in thought or in deed, for we do not believe in it.

We say to the members of our organization—"Give us your best, your most loyal and efficient service, give us continuous and uninterrupted operation, take that sort of an interest in your individual task as you would if the business were all your own, and in return we will give you the fairest and most generous treatment and the best compensation that the result of our common effort makes possible. We will do anything and everything we can to make life and a place in our organization worth while."

That is what we call "Mutual Interest Work"—a real fifty-fifty contribution with no place or need for anything that smacks of so-called "Welfare Work" or "Philanthropy."

It has always been our conviction that industrial stability is the product of that sort of human happiness and human efficiency that is born of a spirit of confidence and of mutual interest, which is in turn the result of much practical, whole-hearted coöperation brought about by an enlarged understanding of the basic principles underlying all of the problems of a particular business, and of what a real pull-together can do for all concerned.

Wherever human beings are brought together in a common undertaking, there is in the beginning so much of misunderstanding, such a lack of understanding that must be overcome before even a start toward the goal of stability or success can be made.

We believe in that sort of an understanding between associated groups of men that will incite the interest, the imagination, and the ambition of the individual, as that is the only way in which a real group spirit, plant spirit, or company spirit can be created and developed.

Without the influence of a real company spirit, born of mutual interest and understanding, no great accomplishment can be made or perpetuated.

Under our mutual interest policies, there has developed in our organization a strong, constructive, indestructible plant spirit which we term "Armco Spirit" and which has gradually defined itself as follows:

"This spirit is a comprehensive, vital force which finds expression in the practical application of policies builded on a platform of Christian principles, in which selfish purpose has no place.

"This spirit combines in proper proportion a spirit of fairness, a square deal always, both in theory and practice; a big, broad view of every problem, cutting out all narrowness and littleness; a spirit of unselfishness, of loyalty, of

(*Continued on page 313*)

## Taking the Pricks Out of the Prickly Pear

A NEW use has been found for the juicy pear—the prickly variety—and you can well envy the cattle of Texas and other States of the Great Southwest that enjoy such a choice ration. Although this variety of fruit differs from the common pear, its growth being restricted to the desert, it belongs to the big fruit family which name it bears.

Machine used for chopping prickly pears so as to shatter the spines and fit them for stock feed

The prickly pear, as its description implies, is covered with spiny thorns which should be removed before cattle partake of the fruit. An ingenious method of removing the spiny growth, as shown in an accompanying photograph, is to singe the plants with a gasoline torch. The artificial treatment thus burns the tiny thorns and the cows can graze with impunity. Otherwise there is danger of the animal suffering from lodgment of a spine in the throat.

Another method of utilizing this desert plant, which proves a valuable emergency ration during the period of parching aridity, is to put the unsinged prickly pears through a chopper. This merciless treatment which the material receives from passing by rapidly revolving knives is such as to shatter the spines and fits the roughage for stock feed.

The prickly pear, however, is more ideally adapted to grazing—less expense and gives better results when fed in the fresh, green state. Scientists of the U. S. Department of Agriculture, recognizing the value of the prickly pear as a stock feed, has begun experiments in Texas and California looking to its perpetuation under cultural conditions. It will thrive where the rainfall is irregular when staple crops succumb to the drought, and its yields are large and cumulative. There are two classifications of the species—the spineless and spiny varieties, each of which has its respective merits.—By *S. R. Winters.*

Applying the gasoline torch in singeing the spines from the prickly pears, so as to make them available for the cattle of the Southwest

## Some Tricks of the Motion-Picture Screen in the Making

IT seems to be quite the accepted thing among film "fans" to expect a favorite actor to climb the fronts of houses and do all manner of other daring feats. Yet if they stopped to analyze some of the "stunts" performed by their screen heroes, they would soon realize that these men could not possibly do the things they apparently do. And here is where we unearth the close alliance between property man and actor especially in comedy productions.

Your hero who climbs up the front of the house can do so in several ways without being a champion climber. In the first place, and where realism is essential, a "front" representing a house can be erected on the studio grounds, provided with ornaments which in reality, are nothing more than staggered rungs of a ladder. These ornaments make it quite a simple matter for the hero to climb or descend the house front.

Then there is another method, with even greater possibilities. That is the "front" that is laid on the studio floor while the cameras "shoot" the scene from above. The hero climbs up the front of the house by crawling on his hands and knees along the studio floor. And the same equipment makes it possible for the "human fly" effect, the dog or horse running up the side of a house, or even the automobile dashing up a wall. The work is quite harmless and simple, to be sure; but so effectively painted is the canvas laid on the floor that it is often a perfect illusion when shown on the screen.

There used to be a certain brand of comedy films which made a great name for itself because of its wonderful action. The audience was held by some bit of clever action every moment of the entire film. The acting was largely in the nature of the so-called "slap-stick" comedy, but it was perhaps the highest class of such comedy turned out until that time.

Now the performers of that brand of film did the most startling things. They smashed into walls and went through houses on motorcycles and in automobiles; they ran mile after mile at hair-raising speed; they went through the floor of one apartment and into the rooms below, along with a deluge of lumber and plaster and what not.

In this case the property man's work was apparent at every turn. In the case of those dashes through walls, the studio carpenters merely constructed a suitable scenery on the "lot," which was so arranged as to break away at any fair provocation. Thus the wooden "bricks" were built into a wall, and the various materials were lightly held together. The same applies to those scenes where performers crashed through a floor. The construction in all such scenes was of the "breaka-way" or "break-apart" variety, cleverly got up so as to make it seem quite the real thing.

Where a vehicle or a performer is shown dashing along at a high rate of speed, with the scenery flashing behind him, the effect can be secured in two ways. First, the effect may be the real thing, in which case the vehicle or performer is filmed from an automobile or motor truck moving in a parallel direction. Secondly, and most likely, it may be faked in the studio yard by means of a merry-go-round arrangement. This consists of a circular platform with suitable scenery on its inner edge, suitably mounted so that it can be revolved. Now then, with the performer or vehicle placed on the platform and with said platform in action, the vehicle or performer merely has to simulate rapid travel while the stationary camera films the subject which does not move very far from a fixed point in the range of the lens. Meanwhile the scenery flashes by at the rear in a convincing enough manner.

Where an automobile is shown riding along a road for mile after mile, the screen audience obviously traveling along with the vehicle, the effect has been produced by mounting the camera either on the car itself, such as on the hood, or on a platform extending in front of the hood, or on a separate car or motor truck in front. In the latter case the motor truck or car generally tows the automobile where fairly close-up action is to be shown, the hauling cable being hidden from the camera in some suitable manner. By hauling the automobile a definite distance is maintained between the camera and the subject, and there is no danger of a collision.

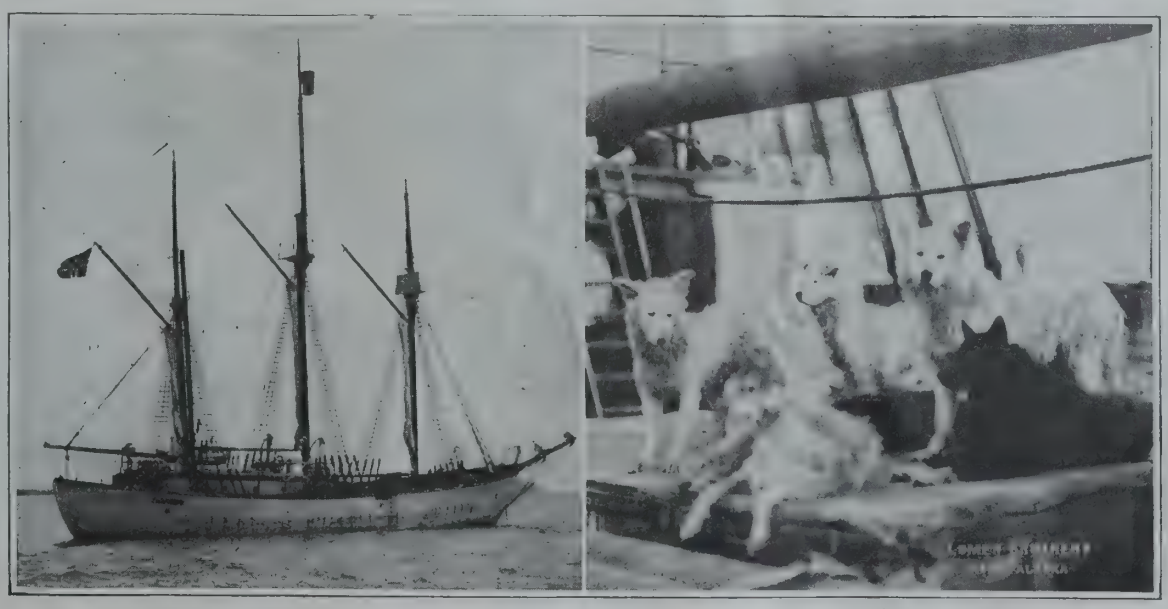
Papier maché bottles, plates, clubs and so on, hinged lamp posts, rubber prison bars—all these things are but a few of the many contributions of the property man to the film comedies. The dishes which the comedians smash on each other's faces with such apparent abandon are certainly of the breakable variety, arranged to smash at the slightest coaxing. Yet a custard pie is always a custard pie: it must be real to produce a reel laugh!

## Working the Tar Sands

NINETEEN hundred and twenty acres of tar sand rights in the Province of Alberta have been leased to General William Lindsay. The general claims that, as a result of investigation and research which has been conducted by him and his associates, a successful process has been evolved for the extraction from the tar sands, on a commercial basis, of the oil, bitumen, and other hydro-carbons they contain. The lease has been granted to permit a thorough test of the process.

## The Return of Amundsen Expedition

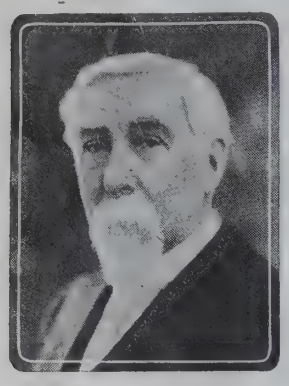
IN connection with the recent arrival of Captain Roald Amundsen in Nome, Alaska, after two years' absence in the Arctic, the accompanying photographs will be of interest. One shows the "Maud," the 900-ton ship which carried the expedition through the polar seas and safely out again. This vessel is specially designed for drifting in the ice packs, having a curious egg-shaped section which makes for its being squeezed up out of the water rather than crushed, when the ice closes in about it. The other view is of the dogs that served the explorer in such good stead in his many expeditions from the ship out over the ice pack.



The ship that carried Amundsen through the Arctic waters, and the dogs that carried him over the ice

# Henry M. Leland's own Story of

After the armistice was signed and the Lincoln Motor Co. was completing its contracts with the government for the production of Liberty Aircraft Motors, we called a conference of our engineering force. The principal members of this force are the same men who have been among the leaders in the development of Leland-built cars during the past twenty years.



*Henry M. Leland*
*President*

We have always been strong advocates of the conference idea. Nothing of vital importance, particularly to car owners, is left to the judgment of one man, no matter how competent he may be.

"Boys" I said—I still call them boys because most of them were not much more than that when they first came with us some 20 years or more ago. "Boys, you have been telling us of your ideas and we are ready for you to go ahead with them.

"You know our ideas as to quality, ruggedness and stability. You have an opportunity now such as you have never had before, to make a thoroughly roadable car, a car that will not only go anywhere but that will go there with ease to the driver and with comfort to the passengers; a car with which it will not be so necessary to pick out only the good roads, a car that will enable people to travel unfrequented highways and to go places they have not been able comfortably to go heretofore.

"Do the job as you have always been accustomed to doing, only do it better. After the experimental cars are finished, we want to figure on at least a year to prove them out, so as to leave no shortcoming for the car owner to discover."

In about six months they had designed several different types and had actually constructed two different types. They were both truly wonderful cars, but we adopted the better of the two. Four engines were built; three of them were installed in chasses and the fourth was assigned for testing on the dynamometer. That was about a year ago.

Then followed the refining process and ferreting out deficiencies. The cars have been subjected to the most severe and the most practical punishment we could prescribe and have successfully withstood endurance tests equal to about five years' service in the hands of the average user.

I believe motorists will agree that the ideal car should possess primarily, six important virtues—good appearance, trustworthiness, long-life, power, economy and comfort. The order of their importance is largely a matter of individual opinion.

## *Appearance and Stability*

In appearance, the cars are substantial, well-proportioned and graceful. There is nothing extreme or overdone in any of the eight body types—just thoroughly dignified; they are cars such as the best citizens, persons of good judgment and refined taste will be proud to own. Their beauty is a type dictated, not by passing fancy, but by a desire for permanent attractiveness. The cars are replete with those many little conveniences which contribute so much to real pleasure and enjoyment.

Those who are familiar with the accomplishments of our engineers and designers—men who have supervised the building of more than 100,000 quality motor cars—know the unusual reputation of those cars for trustworthiness, stability and long life.

These engineers and designers are still working upon the same principles but with the added advantages of greater resources than ever before, greater precision in manufacture and more suitable metal alloys than heretofore employed.

This in itself would make it reasonable to expect that the new car will possess elements of marked stability—elements which in themselves mean true economy over a period of years. And there is the added assurance that comes from the long proving-out period through which the car has been evolved.

## *The Engine*

Our new engine, which embodies a number of unique and distinctive features, but which cannot well be treated in detail here, I regard as the most efficient piece of motor car mechanism I have ever seen.

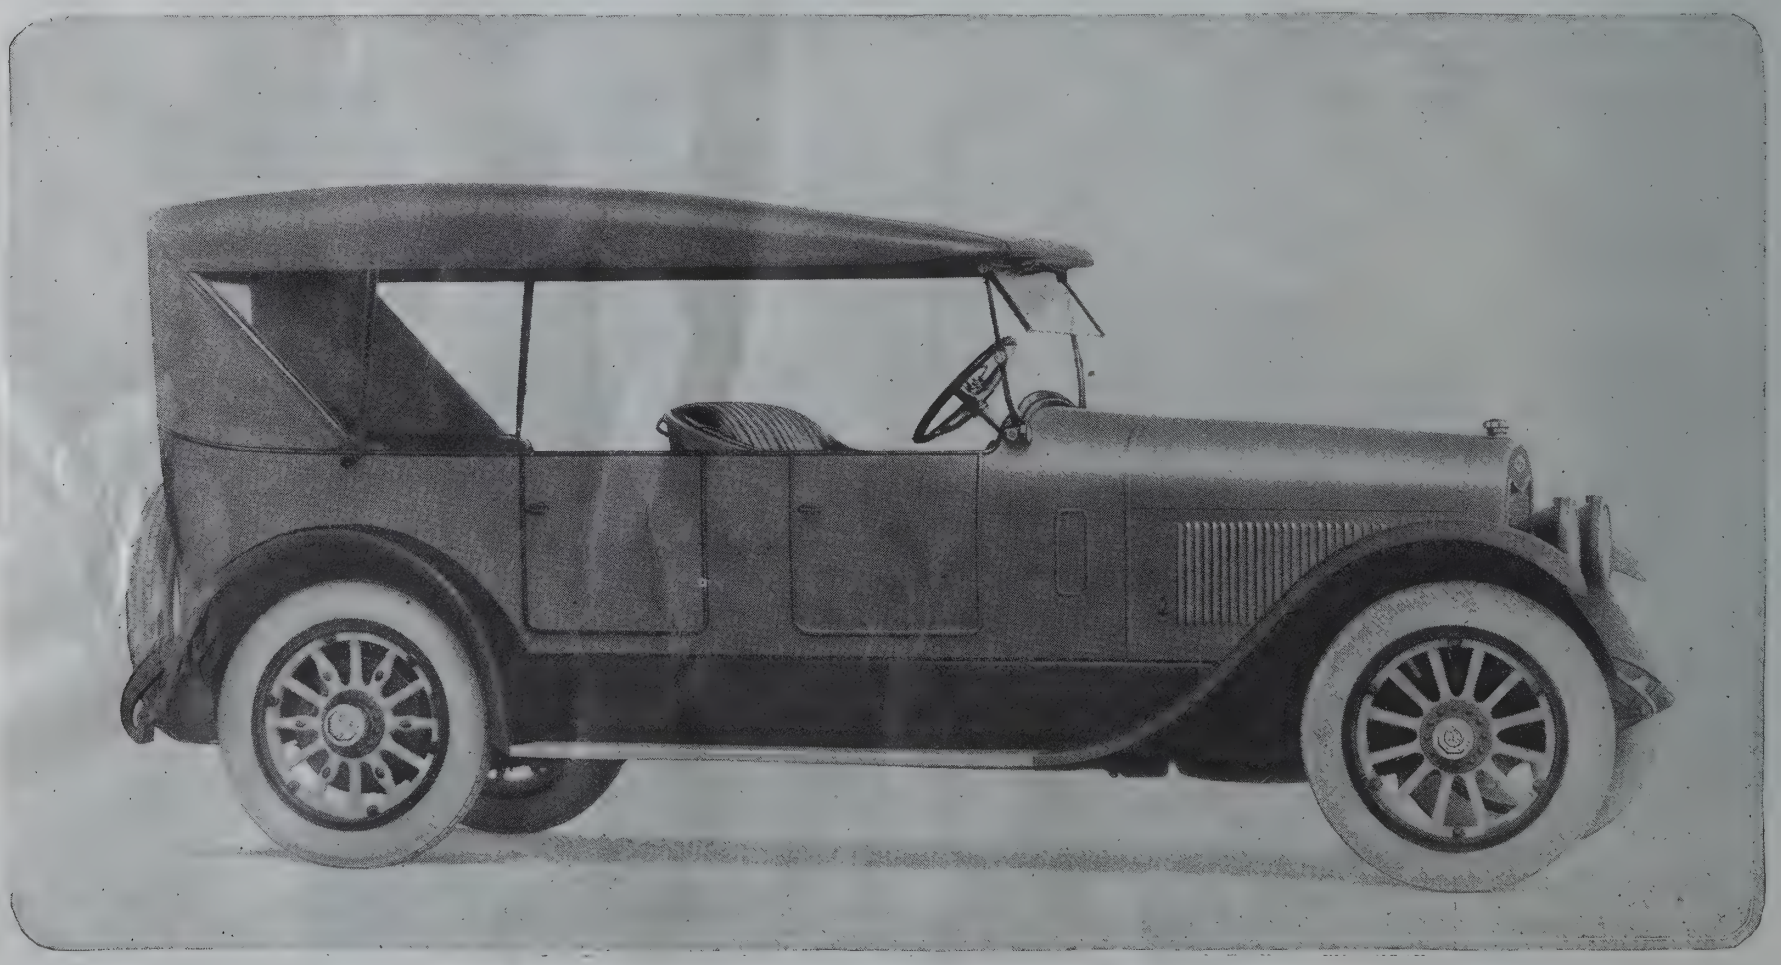
Its piston displacement is 357.8 cubic inches. Its power seems almost limitless; I can hardly conceive of any call to which this engine will not respond.

The wheelbase is 130″ except of the Limousine and Town Cars of which it is 136″. The tires are 33″ x 5″ cords.

## *Comfort and Performance*

In this day of fine cars, it is not easy to imagine a more enchanting way of abridging distance, but let me cite my own experience:—

Our engineers and experimental drivers had been telling us what an unusual car they had; but



*The Seven-Passenger Touring Car*

*(Leland-built Lincoln Cars will*

# the new Leland-built Lincoln Car

frankly, I was a little inclined to discount their enthusiasm.

However, I had occasion to go to Defiance, Ohio, some 125 miles from Detroit—according to the Blue Book. I thought here would be a good opportunity to see for myself just what the car was. There were five of us. The top was up.

We were on a fine stretch with no other vehicles or cross-roads in sight, bowling along serenely at about 40 miles per hour—*so I judged.*

I am constitutionally opposed to speeding, but my interest and curiosity, I suppose it was, got the better of me.

"Step on it and let's see what she can do," I said to Harry, the driver.

"She's doing her best now," he answered.

Doing her best at 40! I was keenly disappointed. My hopes were fast fading when Fred who sat beside the driver called back:—

"Why she's hitting 76 Mr. Leland" and laughingly, "You know this isn't an airplane with a Lincoln Liberty motor."

Perhaps I should have known better had I observed how swiftly the scenery was passing.

My hopes rose. There that car was running just as sweetly and with as little fuss and vibration and with as little apparent effort at 76 as it did at 30—and there was none you could notice at 30.

Periodic vibration, which is something that engineers have tried for years to overcome, was at last absolutely unapparent to me, *at any speed.* There seemed to be an unusual harmonizing of the various functions. And the car was so steady; it seemed to hold the road as if it were in a groove.

I might add in passing that this elimination of the vibration period was not an accidental accomplishment. On the contrary, it was achieved only after much research, experimentation and money outlay.

Elimination of engine vibration, practically to the zero point, is without question a great stride toward prolonging the life not only of the engine itself but of the entire car.

As I said before, I am opposed to speeding; but when a car is made to possess the many other essentials to a real performer—power, acceleration, facile control, etc., speed is a natural consequence. You might call it a by-product, the use of which is entirely at the option of the driver.

A little further on the trip, we came to another stretch; it was pretty rough; several miles of what you might call de-macadamized road. It was a stretch that ordinarily you would not want to take faster than at about 15 miles per hour; but at 41 we were not uncomfortable. The sensation was more like sailing in a yacht as compared to a canoe on a choppy surface.

There was a most agreeable absence of sidesway and violent bouncing—no tendency to throw the passengers up and about.

From a standstill, the car seemed to get away with the grace and ease, but with the swiftness of a thrush, rather than with the flutter of a partridge.

I believe I have ridden in or on almost every kind of conveyance, from the ox-cart to the airplane, but even with all my fond hopes and anticipations, never did I expect to ride in anything which comes so near to what I imagine would be the sensation of flying through space without mechanical means.

The prices are based upon the highest class of materials and workmanship, and upon scientific and economical manufacturing methods, made possible by tremendous preparation in labor-saving machinery, tools and devices—plus knowing how to use them.

While these involve a vast initial expenditure of time and capital, they lend themselves to minimum production cost in large volume. There will be a legitimate margin of profit—no more. There will be nothing added just because we anticipate that motordom will recognize a superior car, nor because we anticipate that the car will afford a degree of satisfaction and comfort heretofore unknown.

*Wilfred C. Leland*
*Vice-Pres. and Gen. Mgr.*

We are obliged to send this story to the publishers some weeks in advance of its appearance. It is expected that cars will be in the hands of Distributors by the date of this publication. Should something unavoidable occur, there may be a little delay in deliveries, but we can foresee nothing now.

I have tried not to be over-enthusiastic but the car *really is* such an innovation that it is not easy to exercise restraint, and I feel confident that your own observations of the car and its performance will abundantly confirm my own impressions.

Henry M. Leland
*President Lincoln Motor Co.*

# Reconstructing Stonehenge

## Work of Preservation That May Solve the Origin of Britain's Most Mysterious Ruin

By Harold J. Shepstone, F.R.G.S.

STONEHENGE, Britain's oldest and most mysterious ruin, is in the hands of the builders. Powerful cranes and the latest modern lifting appliances have invaded its sacred precincts and gradually the work of restoring the monument to something of its former grandeur is being carried out.

General view of the operations at Stonehenge

It was just before the armistice that the strange conglomeration of stones which adorn one of the ridges on Salisbury Plain passed to the nation, and now belongs to the British people. The restoration work is being carried out by the Office of Works, under the direction of Sir Frank Baines, a well-known architect. He is being assisted in the task by the British Society of Antiquarians, who are hoping as a result of the excavations which are being made on the site to learn something of the origin of this strange pile of stones. That has always been the riddle of Stonehenge. Who built it? When was it reared? And for what purpose was it conceived?

Although no one has satisfactorily answered these questions it is nevertheless possible to tell how it originally appeared, despite the fact that many of the stones have fallen, while not a few have entirely disappeared. Some of the smaller ones have been carted away by unscrupulous persons and used in the building of local bridges and other structures. Others again have been broken, and will require special treatment if they are to be used again.

One cannot view the remains of Stonehenge today without marveling at the ingenuity of those early Britons. When it is remembered that it was probably built between 3,500 and 4,000 years ago, that some of the stones turn the scale at 30 and 40 tons apiece, it is clear that it represented in its age a great and momentous undertaking. It is a complicated structure of earthworks, of stones arranged in circles, of stones arranged in horseshoe fashion, and of other isolated stones, and earthen barrows.

First came a long avenue, running from northeast to southwest, defended by ditches on both sides. This leads to a circular earthwork about a hundred yards across. Within this stands the real Stonehenge. First came an outer circle of what archaeologists technically call trilithons; that is, two stones planted upright, side by side like two posts of a door, with a third placed across in the fashion of a lintel. There were thirty of these piers in all, and with their imposts they formed a corona or ring of stones at a height of about sixteen feet from the ground. Within this outer wall, and almost forming a lining to it, stands a smaller circle of stones of which only a few remain. Within these two circles again come two horse-shoe erections in the form of huge trilithons.

Besides these regular structures there are scattered remains. A single stone, called the Sun Stone, lies in the avenue and on the axis of the horse-shoe. It has been so christened because it stands just where any one inside the horse-shoe would see the morning sun at mid-summer appear above the horizon. On it the first rays of the sun would fall, and therefore it is the Sun Stone. Inside the circle two large stones lie prone, respectively called the Alter and the Slaughter Stones.

The work of restoration is being carried out in a most thorough and systematic manner. First a minute survey was made of each stone and the smallest crack or crevice on any one of them noted. These cracks are being left for the present. They will be attended to later, the question of the moment being how to save the stones without doing anything to spoil or alter their looks. After the survey the stones were numbered, a powerful crane erected, and the work of actual reconstruction put in hand.

Attention was first paid to one of the trilithons whose pillars were leaning at a dangerous angle. The lintel, the impost across the top which turned the scale at five tons, was first carefully enclosed in timber baulks and thick layers of felt so that it would not be damaged in any way. It was then lifted by the crane and lowered carefully to the ground. In order that the two pillars should not be damaged they, like the lintel, were protected by timber baulks and felt. Never was the most precious of babies more carefully wrapped up than is one of the monoliths before the jacks which force it into its rightful position are set to work. Not only is it cradled in thick baulks of timber, but every cranny is filled up and padded with felt and wedges and the whole framework is again supported by struts and steel joists.

It is necessary now to lay bare the base and make a new bed for the monolith. The ground round the pillar is outlined into squares of twelve inches. Inside these squares the earth is taken out to a depth of six inches at a time and passed through a sieve. The object here is to salve any object which would throw light upon the actual origin of the monument. A Roman coin, numerous stone implements, and wooden stakes driven into the earth for the purpose, presumably, of keeping the stones upright, have been excavated. It has been found that these huge pillars which stand 21 feet above the ground and weigh between 30 and 40 tons apiece were usually set in the earth to a depth of only three or four feet. With such crude foundations it is wonderful how well the stones have stood.

As soon as the base of the pillar is laid bare the work of moving it back into a perpendicular position is

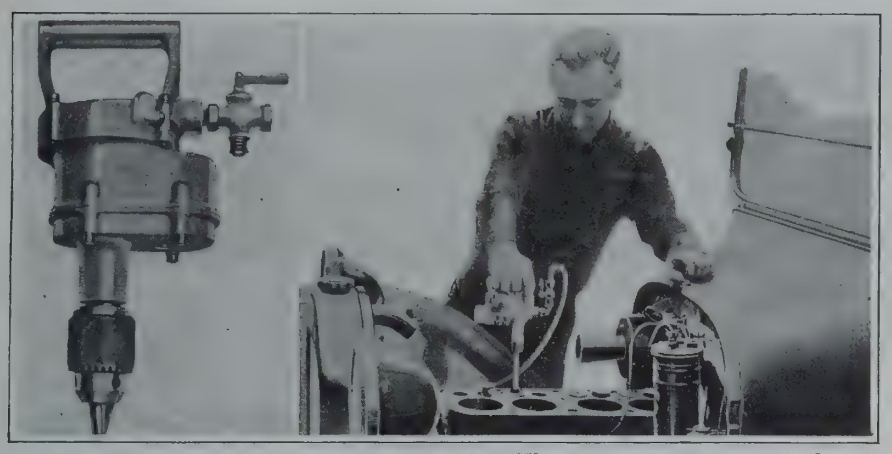
(*Continued on page 314*)

*Left:* Ready for concreting the base. The monolith, still encased in lumber, has already been jacked into position. *Right:* Preparing to lift one of the lintels.

**Some details of the work being undertaken on the Stonehenge monuments**

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*



**Two pneumatic tools for garage work: The pneumatic drill and the pneumatic valve-grinder**

## Putting Air Pressure to Work in the Garage

TWO interesting devices which can be operated on the ordinary garage air tank have been perfected by a Michigan manufacturer. A pneumatic drill weighing 7¼ pounds and a pneumatic valve grinder are the latest developments for the garage mechanic's use.

The drill is capable of being used in close quarters and is particularly serviceable for fender and frame work of all kinds. The device has throttle control permitting proper drilling speeds for various sizes of drills and adaptability to different materials. The motor is of the turbine type and the entire mechanism is enclosed in a dirt-proof casing.

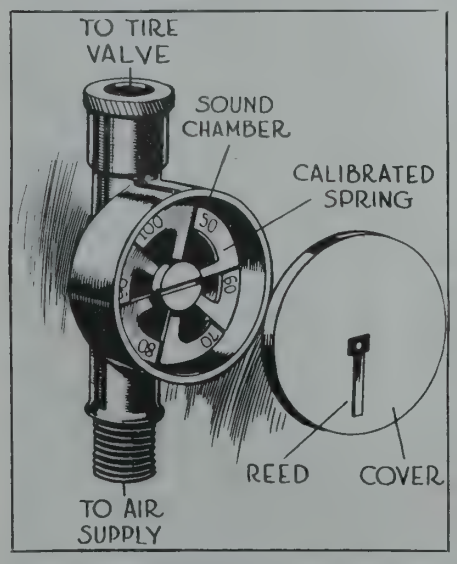
Due to uniform oscillation the valve grinder grinds a more perfect seat than may be obtained by hand drilling. The speed is always under the control of the operator and may be varied from 150 to 1,000 strokes per minute. The grinder is found useful in grinding valves in inaccessible cylinders in various types of motors. All working parts are encased in an aluminum alloy and thus grease, dirt and grinding compound are prevented from getting into the working parts.

## When Rusted Parts Must be Pried Apart

AN automobile mechanic ought to know better than to lose what temper he may have when attempting to remove machine parts which are badly rusted in. This new device will help him cure his distemper, for it is made specially for removing gears, wheels, pulleys, cams, commutators and transmission parts from motors.

A drift and hammer have been used, ordinarily, in removing badly rusted parts, but this method had its dangers and resulted in trouble. The new device is fitted with adjustable arms and locking screws that afford a certain purchase. The pulling screw is of specially treated metal and fitted with a heavy screw point. It is possible to work on the smaller gears and transmissions by adjusting the diameter and using the smaller sized pullers furnished with the outfit.

Special attachments may be used with the puller as well as the adjustable arms. An arbor press attachment is supplied for it which automatically makes the puller available for arbor press work. For bending pipe, straightening shafting and removing universal joint yokes a special pipe bending attachment may be used. For removing solid web flywheels, gears and other similar parts, a stud fork attachment is made use of.



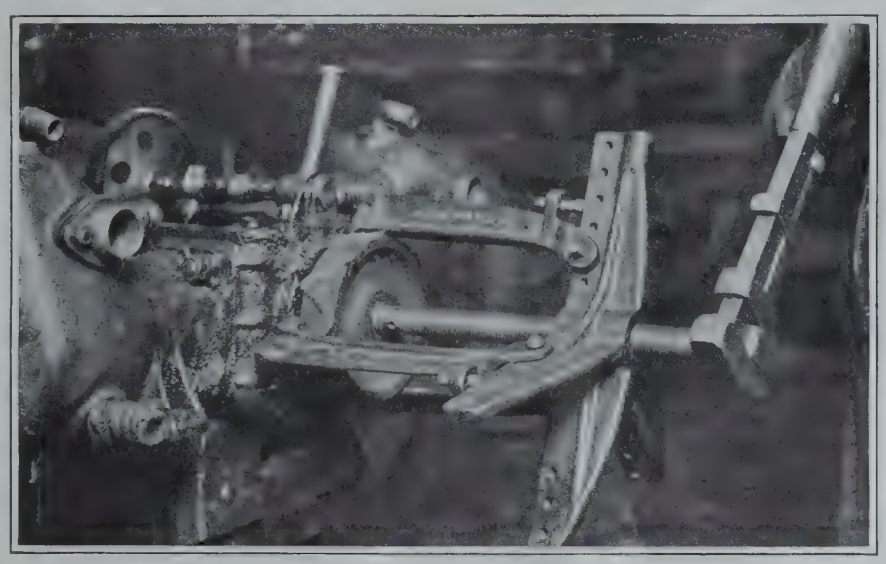
**Tire pressure-indicator which whistles when desired pressure is atttained**

## The Warning Whistle of Tire Over-Inflation

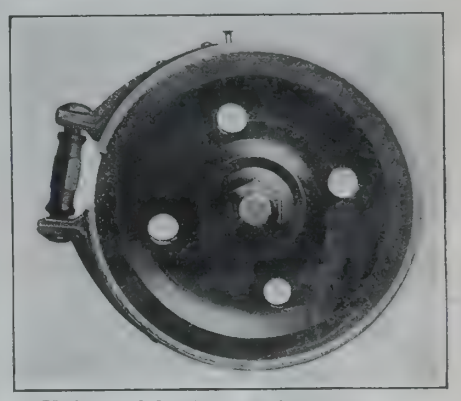
THE latest instance of ingenuity as applied to automobile accessories is the tire pressure-indicator shown in the accompanying drawing. This device consists of a casing connecting the pump connection with the tire valve and having a sounding chamber communicating with the main air passage by a small opening which is closed by a valve. This valve is held upon its seat by a graduated spring, mounted in the sounding chamber, and the cover of the sounding chamber has an opening covered by a harmonic vibrating reed.

In using this device it is first set to the required pressure by removing the cover of the sounding chamber and shifting the graduated spring around its center until the section adjusted for the pressure desired covers the valve and holds it to its seat. After replacing the cover, the indicator is screwed on the valve of the tire and the air supply hose attached. The pump is then started and kept going until the reed in the cover of the indicator sounds the warning that the proper pressure has been reached in the tire.

The action is simple. The spring having been set for a certain pressure, the valve connecting with the main passage will be held upon its seat by the spring as long as the pressure in the tire is less than the predetermined amount. But as soon as the desired pressure is exceeded, the pressure in the main passage will overcome the pressure of the spring, the valve will be lifted from its seat and air will pass into the sounding chamber and will set the reed into vibration, thereby giving the warning sound to the person at the pump.



**Removing a broken flywheel by means of a new device for automobile repairmen**



**Universal brake mandrel recently introduced**

## Simplifying the Relining of Automobile Brakes

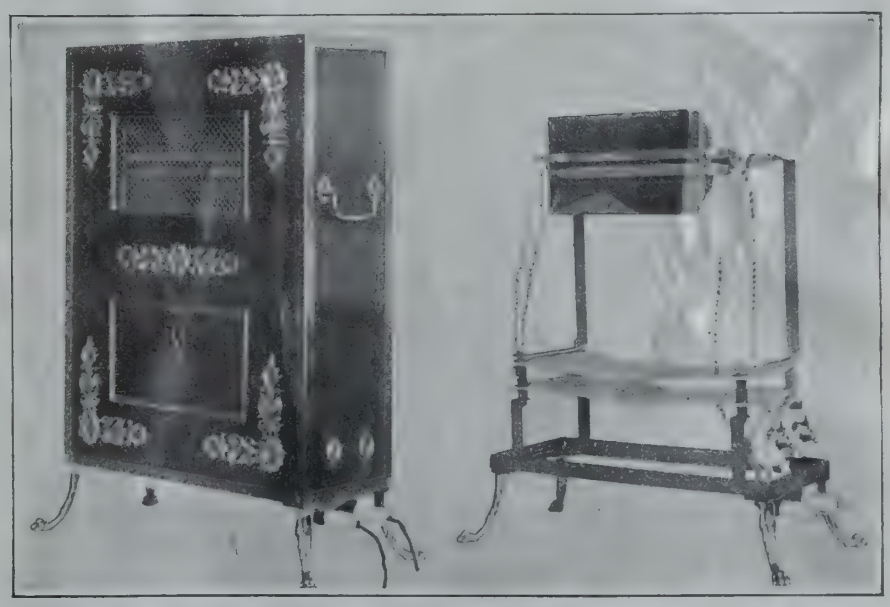
A DEVICE for relining brakes on all cars has been placed on the market by a Detroit manufacturer of automobile accessories. The brake lining and band are firmly clamped on a circular mandrel. The mandrel is turned until the rivet hole in the band comes to an upright position, then a split-rivet is driven in with a hammer blow and the rivet is clinched against the mandrel. This operation is repeated till all the rivets are in place.

Using this device prevents the lining from wrinkling or drawing the lining between the rivets. It is also possible to secure a perfect adjustment of the brakes at the time of replacement.

## Something New in Electric Stoves

FROM France comes a new departure in electric stoves, shown in the accompanying illustration. The heating element of this stove consists of a pair of special resistance rods, placed at the focal point of a copper reflector. Resistance elements are placed below the heating elements for the purpose of cutting down the usual lighting current to the proper degree. The entire mechanism fits into an attractive metal case, as shown.

The amount of heat delivered by this stove can be roughly controlled by turning on one or two of the heating rods, this being accomplished by means of the two toggle type switches shown at one side. The construction is exceptionally light.



**Two views of a new electric stove developed in France to help solve the fuel problem**

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Pertaining to Apparel

SHAWL MUFFLER.—L. GARWITT, 5 Pinehurst Ave., New York, N. Y. Among the objects of this invention is to provide a device for ladies which performs the function of a shawl, a muffler and a hood, and which is adapted to be used with the hood in operative position, or folded down on the muffler, and when in the last mentioned position the muffler will be provided with an ornamental collar. The device is especially adapted for use by motorists.

### Pertaining to Aeronautics

GUN CAMERA.—E. C. BASS, Avenue Edward, Biarritz, France. The object of the invention is to provide a camera especially designed for use on airplanes employed in training aviation schools to the art of aerial warfare with a view to record imaginary hits by photographs of the adversary. Another object is to permit the aviator to handle the camera similar to a gun and to permit of taking accurate aim.

### Electrical Devices

APPARATUS FOR MEASURING OHMIC RESISTANCE OF LIQUIDS AND SOLUTIONS.—T. H. REARDON, 44 W. Main St., North Adams, Mass. This invention relates to an apparatus for measuring ohmic resistance of liquids and solutions; it comprises a vessel of conductive material adapted to contain the liquid, a tube of non-conducting material having one end inserted in the said liquid, and adapted to be filled with the same, conducting material in contact with the liquid at the other and of the tube, an electric circuit connected at one end with the vessel and at its other end with the conducting material in contact with the liquid, and means for measuring the voltage or potential difference of the current in passing through the liquid or solution.

INCANDESCENT LAMP PROTECTING DEVICE.—H. F. WAY, Box 221, Oregon City, Oregon. More especially the invention has to do with what are known as weather-proof type of incandescent lamp sockets used in factories, and its object is to provide means whereby an incandescent lamp utilized with a socket of this type may be rendered inoperative for use with the ordinary type of socket, or with a weather-proof socket unequipped with the invention, the object being to prevent reuse of the lamp in another socket.

### Of Interest to Farmers

SEAT FOR AGRICULTURAL IMPLEMENTS.—J. C. BRIAN, 3938 5th St., N. E., Minneapolis, Minn. This invention has for its object to provide auxiliary mechanism for use in seats of agricultural implements for cushioning the seat, to eliminate shock and jar and to diminish to a minimum the disagreeable side motion, the auxiliary mechanism being designed to be arranged upon the usual pressed steel seat of the implement to provide a spring-supported seat.

AGRICULTURAL IMPLEMENT.—J. W. SCOTT, Falcon, Colo. The invention relates more particularly to clod breakers for use in connection with potato diggers and plows. An object is to provide a clod-breaking machine having a positive crushing, rolling and breaking mechanism, resiliently carried on the implement and being power-driven to effectually crush and pulverize earth being plowed up by the implement. A further object is to provide adjustable means for carrying the resilient tension.

### Of General Interest

STEPLADDER.—O. W. BROWN, JR., 12 Kemball St., Sanford, Me. An object of the invention is to provide a stepladder having rear or supporting legs which can be flared apart at their lower ends to give added support to the ladder and which will be securely held in this position. A further object is to provide a collapsible stepladder which is made of steel or other suitable metal which can be conveniently folded, and which can be secured in expanded form to securely and rigidly support the ladder in operative position.

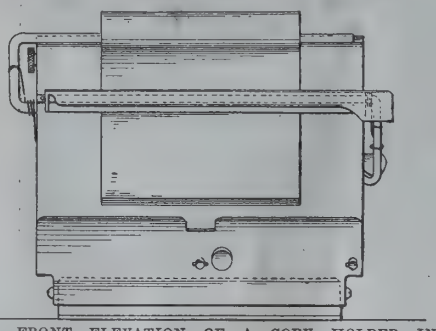
HYDRANT.—W. S. SNYDER, 321 50th Ave. N., Nashville, Tenn. The invention has for its object to provide a hydrant wherein the valve controlling the flow of water is normally spring-closed and is controled to opening position by the action of the hose connection. A further object is to provide a hydrant having drainage and wherein all the parts are protected from freezing, and may be easily removed for repair.

SPONGE RUBBER ARTICLE AND METHOD OF MAKING THE SAME.—J. B. WISHART, 20 N. Westfield St., Trenton, N. J. An object of the invention is to provide a sponge rubber ball or other article of great resiliency. A further object is to provide a method of making sponge rubber articles which results in an article having in its central portion relatively large cells, the cells decreasing in size toward the exterior of the article, and at the exterior the cells being minute so that the surface is practically a smooth continuous one permitting of necessary wear.

PRESSURE BAR MECHANISM.—W. E. MOORE, Janesville, Wis. The invention relates to filling fountain pens having a compressible bag. The object is to provide locking means adapted to engage an interior shoulder in the barrel to normally lock the pressure bar mechanism in position on the barrel but allow free functioning of the same whenever it is desired to fill the fountain pen, and to permit the user to conveniently unlock the mechanism whenever desired.

PRICE MARKING SYSTEM.—H. and L. HOPP, Hopp Press, Inc., 230 W. 17th St., New York, N. Y. This invention relates to numbered cards used for designating prices of articles offered for sale. An object is to provide a simplified price marker system comprising a number of cards with cent marks which are simple and convenient to handle and which may be made up into any price denomination from 1 cent to 99 cents. A further object is to provide a system which embodies very few cards as compared with the usual system.

COPY HOLDER.—A. N. WOODRUFF, 459 Hudson St., New York, N. Y. The invention relates more particularly to copy holders of the movable marker type. An object is to provide a copy holder in which a step-by-step



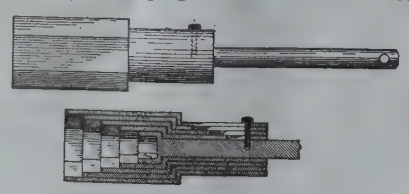
A FRONT ELEVATION OF A COPY HOLDER IN ACCORDANCE WITH THE INVENTION

movement of the marker is obtained by a simple construction, and, at the same time a mechanism of this character which is positive in operation and adaptable to copies having different spaces between the lines, is also provided.

### Hardware and Tools

GRINDING TOOL.—P. U. LOVELACE, Clinton, Okla. An object of the invention is to provide a tool which can be manually operated to regrind or true up crank pins or journals on automobiles, engines and the like after they become flat or out of the round. A further object is to provide a tool which can be manufactured at a reasonable price, and conveniently used without the necessity of employing skilled labor.

WRENCH.—S. C. ROSENBERG, First Natl. Bank Bldg., 42 Church St., New Haven, Conn. An object of the invention is to provide a combination socket wrench having a series of telescoping nested socket members



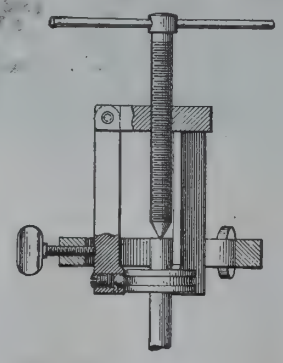
A VIEW IN LONGITUDINAL SECTION

adapted to be quickly adjustable and secured in various longitudinal positions relative to each other so as to present any of the sockets for operation in accordance with the size of the nut or bolt head.

### Machines and Mechanical Devices

NEWSPAPER VENDING MACHINE.—O. J. HOTALING, 420 Ogden St., Newark, N. J. Among the objects of this invention is to provide means for ejecting the newspapers singly. Another object is to provide means for preventing the introduction of a coin or check in the machine when it is empty of newspapers. The invention relates particularly to a device of this character covered by U. S. patent No. 1,285,187 issued Nov. 19, 1918.

BEARING PULLER.—F. J. HEINRICH, 204 N. Yakima Ave., Yakima, Wash. The invention especially relates to a device for pulling magneto and small generator bearings. The



A SECTIONAL PLAN VIEW OF THE PULLER

general object is to provide means for engaging the bearing whereby to securely grip the bearing and to be maintained in position against the tendency to slip and disegage under the pressure exerted endwise against the shaft. Also the engaging member is readily renewable if broken.

SPEED OPERATED CIRCUIT CLOSER.—F. E. TOUCHY, 2518 Ave. I, Galveston, Texas. The invention is more particularly intended for use in connection with an alarm on elevators for grain and other foodstuffs in which the belt not infrequently slips or the elevator chokes owing to too much feed, loose buckets, or an obstruction in the head or boot of the elevator, causing loss of time and sometimes producing fires; when such conditions exist a governor will act through the circuit closer to cause an alarm to be sounded.

### Musical Devices

CUSHION SUPPORT.—F. W. BOCKING, Rifle, Colo. This invention relates to cushion supports in the form of a resilient pad adapted to receive the feet or casters of any form of musical instrument such as victrolas or pianos and which will absorb the sound vibrations ordinarily transmitted by the instrument to the floor, thus improving the tone and eliminating harsh unpleasant tones caused by contact of the instrument with the floor.

### Prime Movers and Their Accessories

VAPORIZER.—M. K. THAYER, Apostol, Wyo. The invention relates generally to internal combustion motors and more particularly to heating means therefor, whose function is to warm up and limber the motor when cold. The object is to provide a simple apparatus of this nature, which will not interfere in any way with the normal operation of the motor and which will be readily accessible and easily perform its intended functions previous to starting.

INTERNAL COMBUSTION ENGINE.—C. C. MANKER, Mayfair Apts., 40 St. James St., Los Angeles, Cal. An object of the invention is to provide a multi-cylinder engine of a relatively light weight, i.e., light in weight compared wth the amount of power generated. A further object is to provide an engine having a "wabbler" with opposite pistons on each side thereof, said opposite pistons being connected by straight piston rods which are operatively connected with the wabbler thus obviating the tendency to side thrusts.

AUTOMATIC GAS CONTROLLER.—E. T. OFELDT, Spring Lake, N. J. This invention relates more particularly to automatic means for controlling the feed of gasolene and air to an internal combustion engine in accordance with the speed of the engine. A further object is to provide means which can be attached to any gasolene engine and which operate as an adjunct to manually control the means so that the desired proportion of gasolene and air can be regulated for starting and then automatically regulated after the engine is warmed up.

### Railways and Their Accessories

CAR DOOR.—R. A. EDGAR, Carlyle, Kan. The invention relates to doors for railroad cars and has for its object to provide a door of the characters specified especially designed for cars used in hauling local merchandise, or for cars where it is desired to inspect the contents at any time and which may be applied to existing doors without change of the car.

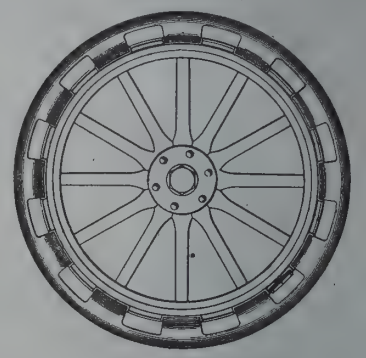
### Pertaining to Recreation

TOY BOOK.—M. GOODMAN, 545 W. 164th St., New York, N. Y. Among the objects of the invention is to provide a book or a device having many characteristics of a book, including covers and movable inside members such as leaves having peculiarly arranged legends, figures, cuts and descriptive matter, means being provided in connection with the book to make the inscriptions carried by the leaves legible not only directly but also indirectly by reflection in a mirror, an object being to provide amusement and to familiarize a child with the principals of reflection.

### Pertaining to Vehicles

HEADLIGHT DIMMER.—P. P. HEIN, 444 E. 79th St., c/o Bory, New York, N. Y. The invention has particular reference to means to nullify the objectional glare commonly accompanying a powerful light. An object is to provide an attachment for a standard lamp, which may be readily applied, sufficiently far in front of the lamp to provide for an appreciable amount of laterally and rearwardly projecting light for illuminating the roadway at the sides of the vehicle and enabling persons at a distance to recognize the nature of the vehicle, yet sufficient light to meet all requirements being projected ahead.

CUSHION TIRE.—I. N. KEIM, 101 Garden St., Mount Holly, N. J. More particularly the invention has for its object to provide a cushion tire designed to be used in lieu of the pneumatic or inner tube inflated tires,



A FACE VIEW OF WHEEL PROVIDED WITH INVENTION

yet arranged to give the desired resiliency, and to withstand heavy service especially when used on truck wheels. Another object is to securely hold the cushion tire against accidental radial displacement.

### Designs

DESIGN FOR A CALENDAR MOUNTING.—A. J. MCDADE, c/o Natl. Calendar Co., 416 N. Y. World Bldg., New York, N. Y.

DESIGN FOR A SPOOL HOLDER.—P. O. MUELLER, 628 Decatur St., Brooklyn, N. Y.

DESIGN FOR A DOLL.—S. P. STARKWEATHER, 2426 Bowditch St., Berkley, Cal. The inventor has been granted two patents of a similar nature.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

# He Rode to Washington on Horseback to Patent the First Fairbanks Scale

Thaddeus Fairbanks, inventor of the platform scale, rode to Washington on horseback from St. Johnsbury, Vt., to obtain his first patent. This was in 1831.

Since that date, Fairbanks Scales have been made in the factory he founded. Always accurate, dependable, honest—these famous scales today are fitting examples of the leadership which they have from the first enjoyed. No other manufacturer has reflected in his product so great a degree of conscientious striving for perfection and so modern a conception of present day precision methods.

The dominance of Fairbanks Scales in industry is universal. They are to be found everywhere that civilization has penetrated. Today more than seventy-five per cent of the world's commerce is weighed on Fairbanks Scales.

# MONARCH LATHES

"Satisfaction to the Purchaser" is the policy of the Monarch organization. From the department for the purchase of raw material through the entire production department and into the sales organization this influence dominates.

It is clearly apparent in the final drastic inspection which every Monarch Lathe receives before receiving its final Okay tag.

The success of this policy is best demonstrated in the fact that a large percentage of the yearly sales go to present users. Each year the Monarch organization builds and sells more Monarchs than there are Lathes produced by any other High Grade Lathe Manufacturer.

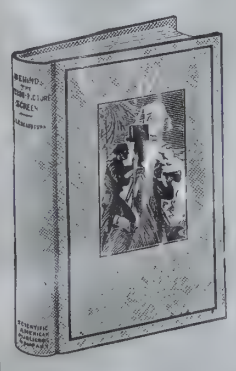
Owners of the world's largest Asbestos Mines



## *Behind the Motion-Picture Screen*

THE mysteries of the "Movies" are bared at last It has remained for Austin C. Lescarboura of the Editorial Staff of the Scientific American to undertake the task of answering the thousand-and-one questions constantly being asked by screen "fans" and aspirants to screen careers, in his book entitled, "Behind the Motion-Picture Sreen." Among the subjects covered in his work are:

Scenarios. The Director and His Work. Motion-Picture Acting. Motion Picture Cameras and How They Work. The Cameraman. In the Land of Make Believe. Studios. Mob Stuff. Tricks of the Screen. Laboratory Work. Pictures in Natural Colors. Microscopic Subjects. Talking Pictures. Animated Cartoons and Sculpture. Motion Pictures in Odd Fields. Motion Pictures in the Home and Business. Present Status and the Future of Motion Pictures.

This book has been written in a simple, interesting, and instructive style. It is not technical; yet it covers all phases of the screen art in an accurate and unbiased manner. Pictures? Certainly; this book is the best illustrated book on the subject—over 300 pictures. Indeed, every right-hand page is a picture page; every left hand a corresponding text page. It is something entirely new in book making. "Behind the Motion-Picture Screen" contains 426 pages and over 300 illustrations, printed on the finest coated paper and bound in an attractive cloth cover measuring 6¼ by 9¼ inches. **Price, $3.50 net; Postage Extra.**

*Special folder containing full description and sample pages, sent on request*

## More Starting Power for the Steam Locomotive

(*Continued from page 295*)

the reverse lever in the corner, and when the locomotive cylinders are getting steam. After steam is admitted to the cylinders the crank-shaft pinion transmits its power through an idler gear to the trailing axle. Hooking up the reverse lever two notches or more automatically disengages the booster and brings it to rest.

The booster puts any locomotive with trailing wheels into the next class above in starting effort, because the trailing wheels act as an additional pair of drivers. On freight trains this means more tons per train because of greater starting effort, and avoids damage to equipment because of a smooth steady start. On passenger trains it means smooth starting and quick acceleration to road speed. This adds to the comfort of the traveling public, protects the equipment from damage, and renders schedules more easily maintained by avoiding delays in starting.

## The Disaster to One of Our Latest Submarines

(*Continued from page 298*)

fifteen to twenty feet of the stern of the craft above water. She was brought up to this position by blowing the water from the after trimming and ballast tanks.

The crew now made heroic efforts to cut through the shell of the vessel, which is here about three-eighths of an inch in thickness. Breast drills and ratchet drills were used, aided by cold chisels, hacksaws and a heavy electric drill. Thoroughly soaked to the skin, rendered dizzy by gas fumes, and without any food, the men, in the words of Commander Cooke, "fought like heroes for their freedom and lives." He tells us that when the current was turned on the electric drill, a large part of the power passed through the body of the man operating it, "knotting his muscles, binding his arms to his side and subjecting him to excruciating agony." Finally, by Thursday morning, the crew had cut a small hole, and managed to make the signals already referred to. By wig-wagging this signal they attracted the attention of the "Alanthus," which gave an alarm and, finally, through the efforts of the crews of this vessel and the American liner, "General George Goethals," food, water and fresh air were passed to the crew and a sufficiently large hole was cut to release them.

The disaster was due to the failure to close the outboard air valve from the control room. In future this valve will be closed *before* the order is given to dive. The valve being open, as soon as the vessel submerged the water found its way in through the induction valves in the various compartments. Fortunately the motor room valve was tightly closed, but the valve in the engine room was not fully closed down and leakage occurred here. The valve in the torpedo room was open, or only partially closed, and the quick flooding of that compartment occurred. The inquiry which will be held will determine definitely whether there was panic in the torpedo room and a failure to realize that the valve had not been driven home, and whether a proper effort was made to close it before the men escaped through the bulkhead.

## Timing the Hundred-Mile-Per-Hour Racer

(*Continued from page 299*)

minutes, three and eight one-hundredths seconds, for an average speed of 99.65 miles per hour. At the start of the qualifying trial he crossed the wire at a time recorded by the clock as 6 hours, 50 minutes, 18 seconds, and 23-hundredths seconds. When he completed the first lap the timing instrument registered 6 hours, 51 minutes, 50 seconds and 6-hundredths seconds. Subtraction of the first time from the second gave 1 minute, 31 and 83-hundredths seconds—the exact time of the lap. This operation was repeated for each lap, the fastest lap being negotiated in 1 minute, 30 and 8-hundredths seconds.

The tape, shown in one of the accompanying photographs, on which DePalma's four record breaking laps are recorded, shows the following figures:

| | Hours | Minutes | Seconds | Hundredths |
|---|---|---|---|---|
| End fourth lap. | 6 | 56 | 21 | 31 |
| End third lap.. | 6 | 54 | 51 | 23 |
| End second lap. | 6 | 53 | 20 | 73 |
| End first lap... | 6 | 51 | 50 | 06 |
| Start first lap... | 6 | 50 | 18 | 23 |

Total time, 4 laps, 6 minutes, 3 and 8 one-hundredths seconds.

Lap time—First lap, 1:31:83. Second lap — 1:30:67. Third lap — 1:30:50. Fourth lap—1:30:08.

## The Toolmaker's Tools

(*Continued from page 302*)

the molten ferro-silicon remains at the bottom. When the furnace is full it is pulled out of the way, the alumina allowed to solidify and the sides taken off. The pig as it is called is then removed and allowed to cool. Several of the companies tap the molten corundum and operate each furnace continuously although the majority use the intermittent type.

The pig, now fused and crystalline corundum, is broken up and sent to the finishing plant where the material is crushed, refined and made ready for wheel manufacture. Much depends upon the skill with which the furnace is operated. The size of the crystals, their freedom from impurities, etc., all play an important part in the quality of the finished product. Carborundum is another product of the electric furnace and is of interest in that it is never found in nature but is purely an artificial product. Its commercial production is due to E. G. Acheson, who in 1891 made the crystalline carbide of silicon in carrying out some experiments on the crystallization of carbon.

The raw materials used in the making of carborundum are quartz or silica, coke, sawdust and salt. The sawdust is added to make the charge porous and to permit the escape of the carbon monoxide formed during the reaction. The raw materials are heaped up around a central core of carbon or graphite and the heat generated in the furnace by the passage of electric current effects the conversion of the carbon and silica of the charge into carborundum or silicon carbide. The salt is added to remove the impurities in the coke and sand, such as iron, by the formation of volatile chlorides.

On dismantling a carborundum furnace after the completion of a run a great variety of products is found. The carbon core is completely converted into graphite and is surrounded by a ring of crystallized carborundum. Next to this is a layer of carborundum powder while outside this again is a ring of siloxicon or fire-sand which is a compound of silicon, carbon and oxygen. This latter is used largely as a refractory substance.

From the above it is seen that the temperature plays an important part in this reaction and it has been found that the range within which the carborundum is formed is from 1,550 to 2,200 degrees Centigrade.

Artificial corundum and carborundum, both of which are sold under a multitude of trade names, form the basis of the modern abrasive industry and are applied to uses best adapted to their characteristics. Aluminous abrasives find their greatest use in the grinding of substances like steel in their characteristics, while carborundum is used to a greater extent on cast iron and in the masonry trades.

SIMONDS SAW STEEL PRODUCTS
MADE RIGHT SINCE 1832

Both make valuable refractory substances and, in passing, carborundum brick is now being successfully used as a lining for boiler furnaces. Carborundum is also used in the elimination of gases from steel since it acts as a powerful de-oxidizer.

In the making of the actual wheel a variety of bonding materials, which serve to hold the abrasive grains together, are used. The greater portion of the wheels is made by the vitrified process. Suitable clays and fluxes are mixed in the proper proportions with the grains of abrasive. After the mixture is just right it is poured into molds and worked up and down to eliminate air bubbles. The molds rest on some absorbent material and the rough wheel soon dries partially out. It is then rough shaved and the central hole bored and is then placed in ovens where all the moisture is driven off.

The wheel is then ready for the kiln and the burning process which follows resembles that in use for porcelain ware. Saggars are used to contain the wheels. The saggars are rings of fireclay covered top and bottom with fireclay tile. Quartz sand is used inside these saggars to prevent the flame from reaching the wheels while being vitrified.

The kiln is started with a slow fire and is 72 hours attaining the maximum temperature of 2,300 degrees Fahrenheit. The kiln is then allowed to cool down gradually for a period of five days, when the charge is drawn.

The burning process is a delicate one and requires much skill. If the temperature is changed too suddenly, the wheels will crack and if they receive too much heat they will be too hard, while if too little, too soft. After being fired the wheels are trued up and are ready for market.

For silicate wheels the same abrasives are employed as for the vitrified process; a different bond is used however. Silicate of soda or waterglass is the principal bonding material used in the manufacture of these wheels. After it has been thoroughly incorporated with the abrasive in mixing machines, the whole mass has a thick adhesive nature. It is then tamped into molds, a cover put on and the whole baked in an oven at about 800 degrees Fahrenheit.

Shellac is the principal ingredient in the bond of elastic wheels. After the mixture has been prepared its consistency is such that if for thin wheels it may be rolled into shallow molds. Thicker wheels are molded under hydraulic pressure or rammed into molds the same as silicate wheels. They are then baked at a low temperature to set the shellac. By the elastic process very thin wheels may be made and used with safety. Wheels as thin as 1/32 inch are procurable and find considerable use in the cutting of high speed steel. Wire mesh is sometimes inserted in them for strength.

## Solving the Labor Problem—I

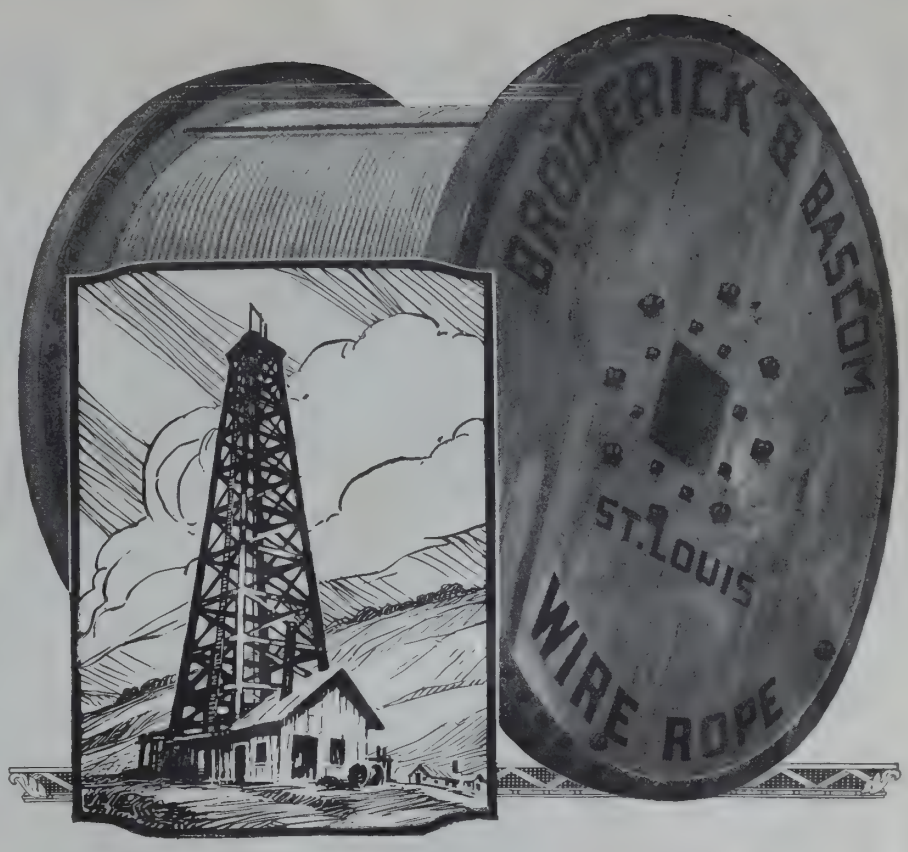
(*Continued from page 304*)

courtesy to and consideration for the other fellow.

"This spirit is, in fact, simply an exemplification of the highest standard of real American citizenship."

The securing of a *condition of mutual confidence* between men and Management is in our opinion the only way to create such a permanent satisfactory relation as will make for real stability and permanent prosperity.

The old policy of suspicion and the attempt by each side to get what it wanted by barter and long-drawn-out and oft-times impossible agreements, or through force born of temporary strength of position, has proven a miserable failure for all concerned. The route "to a condition of mutual confidence" is a long one full of weary days and nights and of the need of much of human sympathy and understanding, of great patience, of much per-



Wire Rope—the Oil Finder

To try to catch up with the great petroleum shortage, hundreds of crews are drilling day and night, sinking narrow holes straight into the earth, seeking oil.

Some strike it at a few hundred feet. Others go thousands without even a promise. Nearly all depend upon wire rope for such success as finally may be attained.

Cables for drilling must be strong because the tools often weigh two tons, and the cable in the hole must be sustained by the upper portion. They must be elastic to give the necessary snap to the tools to drive them into earth or rock at each stroke, and to withstand the shock when the tools meet no resistance. They must also be able to withstand constant rubbing against the sides of the hole.

Such are Broderick & Bascom Invincible Drilling Cables, especially made to meet the peculiar conditions of each oil field.

There are Broderick & Bascom Wire Ropes for every purpose. There is a grade best adapted to your own needs.

B. & B. Yellow Strand is of super-quality for super-service. This is the rope that established unprecedented records at Panama. It has one strand of yellow to distinguish it.

There's economy in buying "quality" wire rope.

severance, and of absolute devotion to all policies born of principle.

It is a long and hard route, but it has an ultimate destination in industrial peace and prosperity.

## Reconstructing Stonehenge

(*Continued from page 308*)

put in hand. Steel joists are attached to the protecting framework, four screw jacks are placed beneath them, and gently, just a fraction of an inch at a time, the stone is lowered back into its original hole. Having obtained from the earth all the evidence of origin that can possibly be found, the base is filled in with concrete thus giving the pillar a solid and sure foundation.

While this giant surgery that is being practised on the trilithons is an interesting thing to see there is something else happening at Stonehenge less spectacular, but to the archaeologists, still more exciting. One by one at an interval of about seven paces from one another a whole ring of newly discovered holes has been laid bare just inside the earthwork which surrounds Stonehenge. An old map gave the clue to their existence. It showed certain—now vanished—depressions in the turf and the excavators determined to ascertain what they meant. Equipped with a heavy steel bar with a sharp point they began their search. Once they found the first hole the others soon followed; the steel bar, instead of encountering the hard chalk, went right through; the turf was turned back and there with all the fascinating accuracy of a puzzle, was the hole just where it ought to be.

It is believed that these holes held stones—not of the size of the huge trilithons; but yet of a good size—and if that be so, then outside the two circles of Stonehenge and the two horse-shoes there was yet another ring, and this was, perhaps, there before Stonehenge as it is known today was built. There are no stones in any of these holes now. It may be that the now prone "Slaughter Stone" which lies outside Stonehenge proper once belonged to this newly found circle.

It appears that at some period these holes were used as burial or cremation places, for there have been found in each of them a quantity of burnt human bones. Many years ago bones of animals were dug up round the Altar Stone, and among the ruins numerous stone implements have been found. Of metals nothing has been unearthed except a small piece of copper.

The discovery of these stone implements and the entire absence of iron and other metals have led many scholars to conclude that Stonehenge was reared when early man in Briton still used tools of stone and when metals were barely known. That takes us back to sixteen or eighteen centuries before the birth of Christ, making Stonehenge somewhere between 3,500 and 4,000 years of age.

At present there is certainly no definite evidence as to its age or for what purpose the early Briton reared this wonderful pile. Some have ascribed it to the Druids, but when they appeared in Briton not only copper, but bronze and iron were known and used. Others have said it was a Buddhist Temple, and still others that it was a fortress, or a meaningless pile which the Romans compelled the Britons to build in order to keep them quiet.

Its origin is wrapped in mystery. We know the date of nearly all the world's great ruins, but not of Stonehenge. It is equally true to say that we have no definite knowledge either as to the use to which it was put. It was hardly reared as a monument to some mighty chief, for no honored dead was ever laid to rest beside the Altar Stone.

But the discovery of animal bones in large numbers round the Altar Stone and the unearthing of burnt human bones by the present restorers inside the earthwork would go to show that it was a temple or worshipping place of the early Britons.

# CONNECTICUT IGNITION

## Full Current—and What It Means To Gasoline

THE Connecticut System is free to deliver the battery's full current to your cylinders because no resistance has been set up anywhere along the line to cut down the flow.

Full current means a fat, eager spark which fires rapidly and completely even today's low-grade fuels.

That fat spark is necessary to get the maximum miles per gallon from your gasoline. With gasoline at 35 cents full current will prevent high fuel bills.

The Automatic Switch guarantees the system's safety in using full current—because when the motor stops the current stops—the switch kicks off automatically and checks the flow.

Will the Connecticut Ignition System be on the next car you buy?

# $5,000 Prize Essay

## The Einstein Theory of Relativity

Mr. Eugene Higgins offers through the SCIENTIFIC AMERICAN a prize of $5,000 for the best essay on the Einstein theories so written that it may be read with profit by an ordinarily intelligent person with no special mathematical training. The competition is open to any person, without restrictions of any sort, subject to the following

**CONDITIONS:**

1. No essays shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Editor will cast the deciding vote.

These bones were the victims of the sacrifices. With these some primeval priest conciliated his deity. But what god it was that the early Britons worshipped amid these circles of massive stones we cannot at present say.

Now that Stonehenge has become the property of the nation and is being restored under the guidance of expert engineers and archaeologists, it is certainly to be hoped that they will be able to throw some light on these much-discussed problems. Already they have been on the ground for six months, but so colossal is the task that another year and perhaps two will expire before their work is finally finished. By that time the riddle of Stonehenge may be solved. Who can tell?

### To Make Hens' Eggs Hard

WE do not refer to the familiar boiling process, but to a method of making the shells thick and tough. This is a trick of the trade known by veteran poultrymen. Make up a supply of lime-water, just as though you were preparing whitewash, and strain off the liquid. Use this for several days in the poultry wet mash, at the rate of about a quart of liquid to 100 hens.

"There is nothing I know," declared a poultryman of many years' experience, "which will stop soft-shelled eggs in a flock so quickly and sensationally as this. Lime, of course, is the principal element in the egg shell, and the limewater supplies it in concentrated form. The eggs will become so hard that you can pour them from a basket just the way you pour water from a pail, and they won't break."

This is a poultry trick you can try on your friends. You can make your flock renowned all over the district for its hard-shelled eggs, and nobody will guess the simple secret.

But ordinarily, soft-shelled eggs in a flock can be corrected by other methods. Always, of course, there ought to be ample oyster shell before the flock. Then the feeding of alfalfa or clover is a great help, as these materials contain considerable lime.

It is possible, of course, to have eggs with shells too hard. At the hatching period, shells of only medium thickness are desired, as they can be broken by the chick without undue labor. The danger at other periods is more from soft-shelled eggs—not so much because they must be handled more carefully, which is the case, but because they break easily in the nest and may cause the flock to acquire the egg-eating habit, an exasperating, disagreeable thing to fight.

### "Flu" Experiments on Monkeys

DEVOTEES of the theory that man is a remote descendant of the ape family will seize with avidity upon the scientific conclusions of medical authorities that monkeys, like folks, are susceptible to the attacks of influenza. Under the direction of Major F. G. Blake and Major R. L. Cecil, the Army Medical School of Washington, D. C., recently completed tests with 22 monkeys to determine the effects of influenza on the ape family.

The monkeys were inoculated with B. influenzae by swabbing the upper respiratory tract with a culture of the disease germ isolated from a case of influenzal pneumonia which had developed in a man. The virulence of the disease was subsequently raised. The period of incubation embraced from three to six hours.

The experiments indicated that influenza exercised the same influence on monkeys as on the human family with respect to its behavior, symptoms, complications and pathology. The medical directors described the action as "an acute self-limited respiratory disease identical with influenza in man." Similar results were obtained when pursuing a different method of inoculation, intra-tracheally, with the exception that one monkey evidenced no signs of infection.

# Are You Hitting at Nothing?

Herbert P. Mee, Material Accountant of the Southern Pacific Railroad at Los Angeles, California, aimed at nothing and hit it—*until*—but let him tell his story himself.

His Letter

"Like most people, I was a drifter, admiring success, weakly wishing for better things to come, with no conception of what those better things were or how to proceed to get them.

"I aimed at nothing and hit it.

"I performed each task that presented itself, did it fairly well and then lay back awaiting the next task, using the spare time to build castles in Spain.

"Paragraph One, Lesson One of your

**Course in Personal Efficiency**

started me to thinking. This I have never ceased to do since. If the Course had done nothing else for me than this, it was well worth the price paid. But it did more.

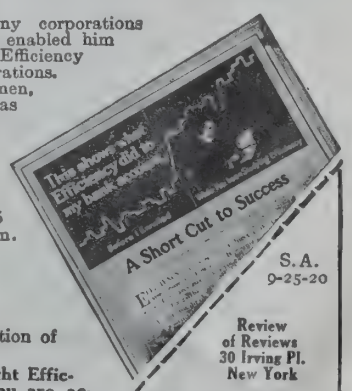
"As an immediate benefit, I have an increased capacity for work which my superiors were not slow to recognize, so that for the most part I am relieved of my old duties and assigned to much more important work.

"Young people who wish to get ahead, but don't know the why, the how or the way, can get the information very cheaply through this Course.

"Old people, given over to pessimism, loss of interest, and with apparently weakened vitality and enthusiasm will get the jolt of their life reading the Course through but once."

Is it skill you want? Efficiency taught the U. S. Navy to shoot 1200 times as well to-day as at Santiago. Is it money? Efficiency brought a great western railroad a million and a half in one year. Is it Economy? A California state official saved $2,700 on one job after he had his third lesson of this course. Is it Education? A prominent man of Louisville, Ky., got his first big step that way from the first lesson of this course.

Harrington Emerson acquired in practical work with many corporations of many kinds the knowledge and experience that enabled him to write this course. He is still the president of an Efficiency Company directing efficiency work in many corporations. In his work he had to teach and train many young men, some of whom to-day hold highly paid positions. He has taught efficiency for forty years; he has taught it for thirty years; during twenty years he slowly collected the data for this course. You can learn from the lessons of this course how you can save an hour, two hours, a dollar, two dollars out of each day and how you can make the day a better day at the same time you can study this course and make yourself efficient in your own life in 15 minutes a day and for little more than one dollar a lesson.



## FREE---This Book

**20 Chapters—In Colors—Illustrated**

Send for this book. It contains the answer to the ever-present question of how to take a "Short Cut to Success." Some of the chapters:

**What is efficiency? For whom is Efficiency? How you are taught Efficiency? Are you ear-minded or eye-minded? Find out what you are actually doing with your time. Most failures are due to guess work. You use only half your power. To what do some men owe their success? Health culture. Personal finances. Mr. Emerson's message to you.**

There is no standing still in life. If you're not going forward, you are going backward. If Efficiency does not grow on you, inefficiency will. This course will send you forward to your goal—it will put you on the shortest, quickest, easiest road to success. Send the coupon for information now—today. It costs you nothing and may be the biggest thing you ever did in your life.

THE ANTISEPTIC LINIMENT

## NEW BOOKS, ETC.

ELECTRICIAN'S HANDY BOOK. By T. O'Conor Sloane, A.M., E.M., Ph.D. New York: The Norman W. Henley Publishing Company, 1920. 12mo.; 823 pp.; 600 engravings.

As a practical survey of the whole electrical field, proceeding gradually from elementary to advanced topics yet keeping all within the compass of an easy handful of book, this improved edition combines the features of a small encyclopedia, a text for the student, and a reference work for the advanced electrician. By ignoring obsolete machinery and methods it makes room for a surprising amount of modern theory and practice.

THE ENGINES OF THE HUMAN BODY. By Arthur Keith, M.D., LL.D., F.R.S. Philadelphia: J. B. Lippincott Company, 1920. 8vo.; 284 pp.; 2 plates, 47 figures.

The general reader will gain a fresh and arresting conception of the body from this simple account, which regards the muscles as reciprocal engines, the bones as levers, the cartilage and synovia as elements of a perfect lubricating system, the heart as a double pump, and the thorax as bellows. We are shown heat-regulating devices, transport and postal systems, workshops and laboratories; in connection with the brain, the master machine, we find cameras, telephones and a stabilizer. Thus the body is viewed from the standpoint of the mechanical engineer, and concrete, vivid impressions result in indelible memories.

PROPORTIONAL FORM. By Samuel Colman, N.A., and C. Arthur Coan, LL.B. New York and London: G. P. Putnam's Sons, 1920. 8vo.; 265 pp.; 156 illustrations.

Those who had the pleasure of seeing "Nature's Harmonic Unity" will enjoy this supplemental volume by the same authors. In it they demonstrate that order, as heaven's first law, is as conspicuously the rule in beauty as in the heavenly bodies. Why do certain forms delight us, while others repel? The work goes far toward answering this natural question by pointing out the laws of a harmony of form analogous to those of motion, music, and color, in which able aid is contributed by Mr. Colman's rich gallery of drawings, geometrical, botanical, architectural, and physiological. The architect and designer will find here basic research and suggestion, but the facts are phrased for "all students of beauty past and present."

NEW GEOGRAPHY, BOOK TWO. By Wallace W. Atwood, B.S., Ph.D. New York: Ginn and Company. 4to.; 304 pp.; maps and illustrations.

The second book of the Frye-Atwood two-book course in geography adopts, for the first time in an American text, the regional treatment used by the best European schools. This divides the world into regions according to life-conditions, and organizes work around the problem method, in which the class studies with the book open before it and is led by judicious questioning to make educative generalizations. The text stresses city geography—in which section nine airplane drawings are a feature—and correlates geography with history. The book's graphic and dramatic qualities engage the undistracted attention of the grammar-school pupil.

APPLIED AERODYNAMICS. By Leonard Bairstow, F.R.S., C.B.E. New York: Longmans, Green and Company, 1920. 8vo.; 565 pp.; illustrated.

"Applied Aerodynamics" is a work of substance and distinction. As adviser to the British Air Ministry the author had access to authoritative sources, and findings from the unpublished reports of the Advisory Committee, covering the period of the war, are generously besprinkled throughout the work. The new knowledge is utilized in a careful exposition of the principles of flight and their practical application. The book includes a description of the different classes of aircraft and develops the laws of stable flight on elementary principles. Then come details of today's practice, with analyses of performance. Experimental modes of obtaining basic facts from actual flight and from models and parts in wind channels are thoroughly canvassed. The photographic studies of flows and eddies are worthy of special mention.

ZOÖLOGY. By T. D. A. Cockerell. Yonkers-on-Hudson, New York: World Book Company, 1920. 8vo.; 580 pp.; illustrated.

A new volume of the "New-World Science Series" is this text-book for colleges and universities by a professor of zoölogy in the University of Colorado. Prof. Cockerell strives to present his information in such manner that a residue of vital importance will be left in the student mind. Details of structure and classification are not carried to a bewildering complexity, and numerous biographical chapters introduce the element of human interest. The New York Zoölogical Gardens contribute many of the excellent photographs, and the drawings were made expressly for this work. Among other subjects handled with a sure touch are the origin and migrations of fauna, genetics, and entomology.

CUBA, PAST AND PRESENT. By A. Hyatt Verrill. New York: Dodd, Mead and Company, 1920. 8vo.; 240 pp.; illustrated.

An inviting volume is this, with enough pre-intervention history to justify its title; for the rest, we find broad sketches of Cuba's physical, climatic and industrial features, intimate glimpses of Havana and Santiago, life and customs, and notes on travel. There is a good folding map, and the new edition incorporates 1919 facts and figures.

TELEPHONIC TRANSMISSION. By J. G. Hill. New York: Longmans, Green and Company, 1920. 8vo.; 400 pp.; 196 diagrams.

Designed as a bridge between mathematical theory and its application to the problems of the telephone engineer, this British work helps him to efficient and economical solutions. The reader will find a great many fully-worked-out examples involving the use of transmission formulæ, and a chapter on transmission measurements; simple proofs of transmission equations are furnished, in addition to the usual proofs requiring a high degree of mathematical knowledge. Practical applications of laws are given generous space, and important cost problems and standard cable practice are carefully set forth.

PROSPECTOR'S FIELD-BOOK AND GUIDE. By H. S. Osborn. Revised by M. W. von Bernewitz. New York: Henry Carey Baird and Company, 1920. 12mo.; 400 pp.; 57 illustrations.

Osborn's original work was of great assistance to prospectors; in the present edition a technologist of acknowledged ability has embodied the new knowledge of the past five years; the need of technical training is emphasized, and the student is taught how to search and how to test. Precious and base metals, and the non-metallic minerals, are given separate chapters; the value of the blowpipe is demonstrated; and oil is dealt with at great length.

CHIMICA ORGANICA. Part I. By Dott. Ettore Molinari. Milan, Italy: Ulrico Hoepli, 1920. 8vo.; 624 pp.; 254 illustrations.

This valuable and substantial work appears in a third edition, revised and amplified. Statistical data accumulated since 1913 are added to the original contents. The first section of the volume deals with analyses, determinations and properties in a general way, and concludes with the classification of organic substances and the official nomenclature. The second section deals specifically with the applications and processes involved in the industrial utilization of important substances such as petroleum, alcohol, acids and their derivatives.

GEOLOGY OF THE MID CONTINENT OIL-FIELDS. By T. O. Bosworth, D.Sc., M.A., F.R.G.S. New York: The Macmillan Company, 1920. 8vo.; 314 pp.; illustrated; folding map.

Kansas, Oklahoma and North Texas embrace the world's greatest developed oil region, and give the world one-third of its production. Dr. Bosworth has drawn freely upon our Government and State bulletins and other available sources of knowledge; he gives the history of the region's development, detailed statistics of production, the general geological structure of the territory, and localized structures, presenting tables and analyses and providing much information as to processes. It is a compendium that, from the geologist's point of view, is of decided value.

THE WESTINGHOUSE E-T AIR BRAKE INSTRUCTION POCKET BOOK. By W. W. Wood. New York: The Norman W. Henley Publishing Company, 1920. 8vo.; 258 pp.; illustrated.

Patient, capable instruction marks this revised edition of a well-known pocket book, and the man who demands full knowledge in contradistinction to a limited grasp of material details will find satisfaction in the work. Particularly noticeable are the self-explanatory illustrations, in which each zone of air pressure is given its own distinguishing color. Examination questions and answers cover the No. 5 and No. 6 equipment, their operation, and approved procedure in case of breaks.

# OWNERS' FAITH
## *in*
# WHITE TRUCKS

THE following list of large investments in White fleets shows the faith large truck owners have in White equipment.

| | | | |
|---|---|---|---|
| **2 owners have invested over** | **$2,000,000** | | |
| **4 owners have invested between** | **1,000,000** | **and** | **$2,000,000** |
| **5 owners have invested between** | **500,000** | **and** | **1,000,000** |
| **22 owners have invested between** | **250,000** | **and** | **500,000** |
| **82 owners have invested between** | **100,000** | **and** | **250,000** |

Experienced truck users *know* truck value in terms of earning power, through actual performance of one truck against another.

They *know* that White Trucks do the most work for the least money, and they back that knowledge by increasing their investments year after year.

The purchaser of one or a few trucks can safely follow their example.

**THE WHITE COMPANY**
**CLEVELAND**

IN the bearings sponsored by SKF its type of anti-friction bearings have been developed to their highest perfection. And SKF further provides an engineering service not only to assure to itself proper application and use of SKF marked products but to help the buyer to fully capitalize the mechanical value built into each device. This service is freely offered and is being continually broadened and advanced by laboratory research that is international in scope. You are assured a similar service behind every product bearing the mark—

SKF

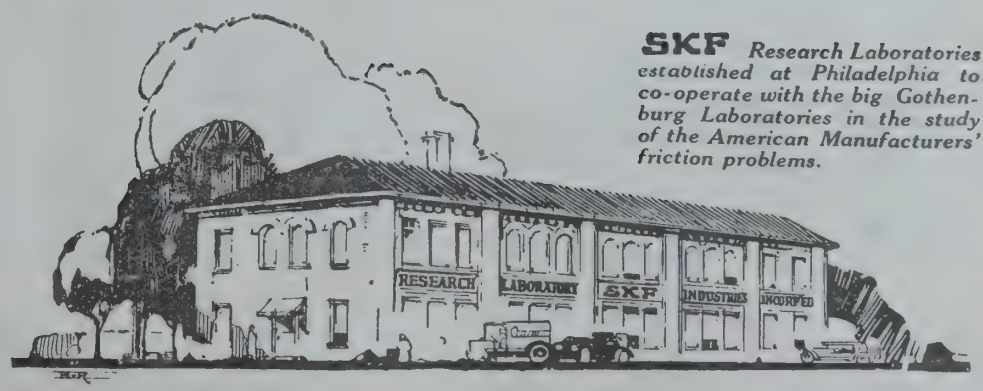
*Among these products now offered are:*

Single row deep grove ball bearings
Double row self-aligning ball bearings
Steel balls
Transmission equipment

**SKF Industries, Inc.**
**165 Broadway, New York City**

Supervising at the request of the stockholders

The Hess-Bright Manufacturing Co.
**SKF** Ball Bearing Co.
Atlas Ball Co.
Hubbard Machine Co.
**SKF** Research Laboratories



**SKF** *Research Laboratories established at Philadelphia to co-operate with the big Gothenburg Laboratories in the study of the American Manufacturers' friction problems.*

# Announcing Packard "Single Six"

## *The 10-Year Car*

WE have always made large cars designed for maximum speed, great power, and all the roominess that goes with a long wheelbase. The ultimate development has been the Twin Six, which has firmly established itself in the regard of the public, and which we have been producing and marketing for a number of years.

Packard reputation for motor cars rests solidly upon the *Twin Six,* and it always will!

Packard

But there has for years been an insistent demand for another car to supplement the Twin Six: a car of shorter wheelbase and lighter weight, a general-purpose car of great maneuverability in traffic, one that would park in a short space at the curb.

And the demand was that this light car should give unusual gasoline mileage and tire mileage, and finally, that it should be designed and built Packard-wise, and therefore be able to keep out of the repair shop longest and to require least attention from its owner or driver.

We thought it over and studied the problem for a good many years, during all of which we were accumulating experience in the design and production of the highest possible grade of car.

We have at various times during the past ten years designed a light-weight companion to our larger cars, but were never entirely satisfied with our efforts.

Then the war broke out in 1914, and believing that America would inevitably become involved, we turned our attention to designing airplane engines, and from then to the close of the war had a thoroughly successful experience in designing and manufacturing airplane motors, which, as you know, must give the greatest power with the least possible weight.

* * *

We learned a great deal through this experience that was applicable to the automobile, and towards the close of the war we felt we were finally well equipped by experience to design the light-weight car.

Meanwhile, with a constantly growing talk of congestion in traffic, and increasing cost of gasoline, tires and other supplies, the demand for the light car became more and more insistent.

* * *

We have taken several years for the development and perfection of this new Packard, but we believe we have accomplished what we set out to do, and take now a pride in announcing that the Packard Single Six will soon be ready. It will be manufactured alongside the Twin Six and by the same matured and experienced organization.

The new car is of five-passenger capacity and will be offered in Touring, Runabout, Coupé and Brougham or Sedan.

The motor has six cylinders, 3⅜" bore by 4½" stroke. It is therefore of medium size, and despite its light weight is very sturdily built.

It is equipped with the Fuelizer.

The *Single Six* motor is new throughout, but it is not experimental.

It includes every principle of good engineering that our experience has shown to make for maximum power, coupled with silent operation and freedom from annoying troubles. We have failed of our intentions if we have not produced a motor that will run longer and require less attention than any other.

Our chassis design is very simple and clean. Its light weight, together with its unusually efficient motor, result in a very economical car.

As an instance of this, in our test driving in cross-country runs, we have made over twenty miles to the gallon of gasoline. Of course, in congested city driving, the mileage will not be so high.

Average tire mileage can be expected to exceed 15,000 miles. In our extensive experimental driving of this new car, we have had some tires in fair condition at the end of 25,000 miles.

It is an agreeable car to operate, having the easiest possible steering, the lightest clutch action, the shortest turning radius and, we believe, all those qualities that you would like to have in a light-weight car for general purposes.

The workmanship and finish are Packard throughout.

Packard

The greatest obtainable luxury, the maximum power, and the ultimate in road-ability, must always be found in the large car. That is the field in which the Packard Twin Six will always be dominant.

In this new car we have not attempted to compete in that field, but rather to produce an active, easily-operated, high-grade, light car, with all the elements of efficiency, economy of operation and, above all, long life.

There are Packard cars today, designed years ago, that are nearing the half-million mark in miles traveled.

The new Single Six is also, we confidently believe, a TEN-YEAR CAR.

The price of the Touring Car is $3640 at Detroit.

## The Future as Suggested by Developments of the Past Seventy-five Years

INEVITABLY, after such an extensive retrospect of the fields of practical science as we have made in this commemoration of the 75th anniversary of the founding of the SCIENTIFIC AMERICAN, the thoughts of many of us will turn to the future. An outstanding impression left by a perusal of the early volumes of the SCIENTIFIC AMERICAN is the surprisingly large number of forecasts which the passage of the years has shown to be well founded, and we may find some not altogether unprofitable diversion in using the present opportunity to turn from the accomplishments of the past to possible developments of the future.

### Civil Engineering

The profession of civil engineering has been so long established and has proceeded along such definite lines, that the future will probably witness no radical changes either in its principles or practice. The outstanding feature will be the scale on which the civil engineer, thanks to improvements in machinery and general appliances, will attack and put through works of unprecedented magnitude. The construction of the North River Bridge, now assured, will be followed ultimately by the building of a few other long-span bridges of equal or greater magnitude, such, for instance as a 4,000-foot span across the waters of the Golden Gate at San Francisco, another great cantilever bridge connecting Oakland with that city, and the proposed bridge at Detroit across the Detroit River. Where bridging is impossible, resort will be had to tunnelling, and it is probable that the next decade will see the completion of the 21-mile Channel tunnel, to be followed by one between Scotland and Ireland; while he would be a bold prophet who denied the possibility of devising methods by which a subaqueous crossing of the Straits of Gibraltar will be worked out, in spite of the depth of water and the unfavorable condition of the underlying material. In this connection, it is safe to predict that the ugly, noisy and distracting elevated railways will be banished from our city streets and placed underground, and that the imminence of a deadlock in surface transportation will lead in congested centers, to the double-decking of streets, with the separation of light and heavy traffic.

The rate at which we are using up our supplies of raw materials, in the shape of iron ores for the production of a sufficiency of steel, will become, if it has not already become, a serious problem. We may have to turn to other materials, and it is possible that a workable substitute, for certain kinds of structural work, will be found in the direction of improved aluminum alloys, with a lower ratio of bulk to strength and of lower cost.

The future will see a great development of both barge and ship canals—barge canals for the carriage of commodities in bulk which require no great haste in transit, and ship canals to shorten sea travel, or, as in the case of the proposed ship canal from the Lakes to the Atlantic, to enable freight to be carried from interior points to foreign ports without breaking bulk.

### Transportation by Land

As regards transportation the question arises: Will the steam railroad continue to hold the primary position in the transport of passengers and freight? So far as speed and carrying capacity are concerned, they seem to have about reached the limit. The outside dimensions of mammoth locomotives, as represented by the "Virginian," are limited by the height and width of permanent structures. The steel Pullman weighing from seventy-five to eighty tons, and the latest steel coal cars of seventy-five tons' capacity, are subject to the same limitations. If rolling stock continues to increase in weight it will be necessary to revise our methods of track construction, and on the trunk lines of the future we may look to see roadbeds with a concrete foundation covered with broken-stone ballast, and laid with rails of from 150 to 200 pounds to the yard. Experience with the 125-pound steel rail now under test by the Pennsylvania Railroad, has shown that the life, both of track and rolling stock, is prolonged by using very heavy rails, of deep section, rolled from a harder steel.

If the railroad is to hold its own with the automobile, the airplane and the dirigible, the steam locomotive must gradually give way to the electric motor. Gradually, and with increasing efficiency, electric traction will be extended in its application, until the time arrives when our whole railroad system will be run from great central and inter-connected power plants, located at the sources of water power and at the mines. A careful estimate of the resulting economies were our whole railroad system electrified, reveals the astonishing fact that 122,500,000 tons of coal would be saved in every twelve months of operation. With the introduction of electric traction and improved track, we may look for an increase in train speed, and concurrently with this there will be an extensive application of the automatic stop. If it be not introduced voluntarily by the railroad companies, legislation, as in the case of the automatic coupler and the airbrake, will render it everywhere obligatory.

The immediate future will witness a keen competition between the automobile and the railroad; but this will ultimately give way to a well adjusted coöperation, as it comes to be realized that the one is the complement of the other. The main highways of the future will be of concrete construction. There will be a great increase in motor bus travel, and the bus will be developed until the passenger may make his journey over the highways with as much comfort and convenience as he now enjoys on the steam railroad. Ultimately, the "trunk" highways, if we may borrow a railroad term, will be widened out to accommodate four vehicles abreast, motor-truck traffic occupying the center, and fast passenger traffic the outside of the roadbed. It will not be many years before the pneumatic tire will be in universal use for motor-truck service. The motor of the future will be multi-cylindered, sixes and eights predominating; engine weights will be reduced; and power will be sought in high speed of revolution.

Apparently the only limit to the growth of the automobile will be the question of fuel supply. At the present rate of consumption, it is certain that before another seventy-five years have passed, some moderate-priced substitute for gasoline must be found. Otherwise the use of the automobile will have to be greatly curtailed.

### Transportation by Sea

When we come to the question of travel by sea, we can speak with more certainty of the developments of the future. It is probable that in such ships as the "Leviathan" and the "Aquitania," we have reached the limit of size and luxuriance. For many years the steamship companies have claimed that these ships are profitable only as advertisements, and it is well understood that the best revenue earners and, in some respects, the most comfortable ships are vessels of the so-called intermediate type, which can carry a large passenger list and a big load of freight and maintain a speed of sixteen to eighteen knots. Not for many decades to come, if ever, will the Atlantic see a repetition of the speed contest for the famous "Blue Ribbon of the Atlantic." If such competition should occur again, it will be between boats of a special type, of moderate size, carrying no freight and only first-class passengers, and charging sufficiently high rates to cover the great cost of operation. If any firm wished to do so, it would be perfectly possible to build a turbine-driven, 35-knot transatlantic liner provided with limited and extremely high-priced accommodations. In the immediate future there will be an increasing use of both the electric and the geared drive, and if the economies claimed for the electric drive on our warships can be realized in the merchant service, the electric drive must ultimately become the universal type. Meanwhile, as the problems of the oil engine are mastered and the size of the individual cylinder increases, there will be a corresponding increase in the number of oil-driven ships. There is everything to be said in favor of the marine oil engine, and practically nothing against it. The oil engine, because of its many economies will ultimately drive out the marine steam engine, and nothing short of the giving out of the oil supply can stop its progress. When the oil wells of the world run dry, the motor-driven ship will have to give place to the steamship with its coal-fired boiler.

### Aviation

IT is quite possible that the future historian will set down the present year as marking a new era in the history of aviation—the era of metal construction. As an advocate from the very first of the monoplane as against the multi-winged type, we are gratified to note that, so far as America is concerned, two of her entries for the approaching international cup contest are of the monoplane type, and that the most important of the new airplane postal routes, that from New York to San Francisco, is being operated by all-metal monoplanes. The monoplane is ideal for high speed, and because of its lower head resistance, or drift, it is the most economical type at any speed. It has been built in fairly large sizes, although, for the present, it seems likely that in the largest airplanes, recourse will be had to the biplane type. Excellent progress is being made in the development of a more effective form of wing, and unquestionably the airplane of the future will be capable of changing the angle of incidence during flight. When this has been done, the difficulties and dangers of taking off and landing will be reduced to a minimum, and the pilot will have a wider range of choice for a landing place in cases of forced descent. Similarly, in the near future we look to see a thoroughly reliable variable pitch propeller put upon the market. Results obtained with this device at the Army Flying Grounds at McCook Field are very encouraging; for it has been found practicable to change the pitch of the propeller to suit the altitude, and also to reverse it entirely at the moment of landing, thereby securing a braking effect, so powerful as to bring the machine very quickly to rest after it has reached the ground.

There will be a steady increase in the size both of airplanes and dirigibles. It is now realized that there is no inherent disadvantage, as was at first supposed, resulting from increase of size in the airplane. At the present time a seaplane is under construction which has a wing spread of nearly 250 feet; whose weight is over 50 tons, and whose radius is over 4,000 miles on one filling of the fuel tanks. The boat is of such size that full stateroom accommodation is provided for a considerable complement of passengers and crew. This is an enormous advance at one stride, and suggests that future airplanes and seaplanes may ultimately rival the smaller ocean-going steamships in dimensions. Reliability will be assured by a multiplicity of engines, the flying boat above mentioned having no less than eight, with a total capacity of nearly 5,000 horse-power As far as the dirigible is concerned, any increase in dimensions brings with it a greater relative increase in carrying power and all-around efficiency. Now that the question of landing has been solved by the provision of mooring towers, the risk of landing, even in heavy weather, has been eliminated. The flight of R-34 last summer from England to America and back has established the feasibility of trans-oceanic travel, and the last machine to be completed, R-80, in its recent trial trips has shown great improvement in control and maneuverability over R-34. This latest of the dirigibles has a cruising radius of 6,400 miles and a maximum speed of 65 miles per hour. Aerial travel will be

divided between the two types, the dirigible being used for long distance and trans-oceanic travel, while the airplane will be the standard machine on overland routes, where the distances between stops are shorter. Experimental work which is being carried on in this country in producing a steam drive for airplane service has given such promising results, that it is quite possible a combined steam boiler and steam turbine, admirably adapted for the larger machines, will be in extensive use within the next few years. One of the great advantages possessed by steam-driven airplanes would be the absence of the loud exhaust, an improvement which will be especially appreciated by the airplane passenger, and will prove to be of great tactical advantage in naval and military airplane service.

### Pure Science

When the investigator in the field of pure science has unearthed new facts and new principles, it is often possible to predict with some accuracy just what use the inventor will make of these. But prediction in the field of pure science is another matter. The scientist sets forth over an uncharted sea, and the scribe, left behind on the dock, is asked what he may find at the other side of the waters. If the scribe knew, the scientist would not have to make his voyage.

Nevertheless, sometimes the scribe knows something about the ship in which the scientist is sailing, and enough about the waters over which he is to pass to hazard a guess as to his direction. And if one thing seems clearer than anything else when we try to see in what direction the ship of science is heading, it is that the process of generalization, shown on another page to have been the dominant note in scientific progress for the past three-quarters of a century, has by no means reached its culmination. We have but scratched the surface of the discoveries that wait to be made regarding the essential unity of matter and energy, and the direction of major achievement in the science of the next seventy-five years is here clearly outlined. If we are ever to find the way to utilize for our own purposes the vast store of energy locked up in matter, the way will lie through a better understanding of just what the correspondence is between these two entities. More specific than this we cannot be, or we should be steering the ship instead of watching from the shores for its return.

In the field of biology prediction can be more specific. We shall continue to pick up information as to how heredity works, until we shall be pretty well able to determine in advance physical and mental characteristics of animals a long way up the scale from the sand flies to which experiment is so far confined. Doubtless the goal here is the human animal; whether that goal will be attained is a matter of guesswork. If balked in the direct attack, we may at least hope to prevent the production of types running too strongly in the wrong directions physically and mentally.

Every age sees a new science—a whole body of phenomena and of the principles that govern them—developed where previously we had not even been conscious that there was a void in our knowledge. In the eighteenth century it was electricity; in the nineteenth, psychology. In the twentieth, it is the conviction of the SCIENTIFIC AMERICAN that it will be the field to which the rather unsatisfactory name of psychic has been attached.

We make this statement without any reference to the question of personal survival or that of communication with those alleged so to have survived. But the fact can hardly be escaped that there is a growing fund of well authenticated phenomena which are explained by no natural law yet formulated, and which seem to require that we postulate the existence of some force operated, consciously or unconsciously, by the human brain. Nobody, for instance, can deny the phenomenon of hypnosis. No careful person is going to deny categorically the accumulating evidence that there really is some sort of communication between individuals widely separated in space, to which the general name of mind-reading or thought-transferance or telepathy has been provisionally applied. We think we may, without being accused of having fallen victim to the post-war hysteria, suggest that when all cases of fraud and hypnosis have been ruled out, there is a residuum of material demonstrations of an as yet intangible force—things to which the hateful names of spirit-rapping, table-tipping, levitation, etc., must be applied until we get a more respectable term to take their collective place.

On all these grounds we are inclined to predict that there exists a force, operated through action of the human brain, that is capable of producing sensible effects and effects upon another brain. The science of tomorrow will tell us what this force is and will give us a control over it which may turn out to be as complete as our control over the electric impulses which today we shoot through the ether in utter defiance of all the experiment and all the knowledge and all the common sense of a generation ago.

### Applied Electricity

Electricity in the rôle of man's faithful slave is so relatively young that one hesitates to say much regarding its future. Only yesterday Edison was trying all kinds of materials in order to obtain a suitable incandescent lamp filament; Bell was struggling with a toy called the telephone; and several experimenters were entertaining their friends by transporting them about on crude electric cars. And if such remarkable progress has been made in but a few past decades, there is a wonderful future surely for this new art.

In the generation of electricity there will doubtless be progress, but it seems certain that such progress will not be spectacular. The generators of today have attained very high efficiency, and unless some new principle displaces the electro-magnetic type on which our present power plants are based, the generators of tomorrow will merely be larger and of far greater output. This great power will be transmitted thousands of miles, as compared with three or four hundred miles today. There is no doubt but that the problem of long-distance transmission will be solved, and the solution will be in the nature of better insulation and the consequent use of extreme potentials. Better transmission, in turn, will make it possible and feasible to harness the mountain streams that are far removed from civilization. It will also bring about the reduction of coal shipments; for why transport coal hundreds and thousands of miles when it can be burned at the mines to drive generators, and its power can be transmitted electrically to the distant consumer?

The electric furnace is in its infancy. It will reveal many new electro-chemical wonders when its possibilities are developed on a larger scale through the medium of cheaper current. Electric heating too is bound to be extended as current becomes cheaper through the harnessing of water power and the solving of long-distance transmission. Electric cooking on a vast scale only waits for a better rate per kilowatt hour.

In the field of communication we can look forward to great things. The introduction of the vacuum tube—that marvelous offspring of the incandescent lamp—seems to reveal no end of wonders. Engineers and experimenters are daily discovering new uses for the vacuum tube in telephony and radio work. We already have trans-continental telephony, and we may look forward to transatlantic telephony in the no distant future.

Radio communication is a newcomer in the field of applied electricity, yet it is a giant in point of development. True, this method of communication still leaves much to be desired, and it is the missing factors that must be supplied by future workers. Static—electric disturbances of the atmosphere—must soon be eliminated. Further introduction of faster automatic transmitters is certain, so that a tremendous volume of traffic will be handled by a given station, with subsequent reduction in toll rates.

In the field of illumination electricity has found a ready place. Nothing else can compete with it. And there seems no reason to doubt the ever-increasing use of electricity for illumination, especially when we are already facing serious shortage of heavy oils and other ingredients entering into the manufacture of illuminating gas. We have the one-half watt per candlepower lamp now; is it not safe to prophesy the one-tenth watt per candlepower lamp in the future?

The transmission of photographs over wires and by wireless; seeing the image of the person to whom you are speaking over the telephone; subscribing to concerts and motion pictures for the home, the service being distributed over the usual telephone lines by a central studio; frictionless electro-magnetic transportation systems that will attain hundreds of miles per hour; the transmission of electricity by wireless—all these things seem visionary today, but certainly no more so than our present attainments would have seemed to our forefathers of 1845.

### Industrial Progress

Whatever may be the reason for the present shortage of labor, one thing seems certain, and that is the permancy of labor shortage or, to put it another way, the continuation of high labor costs. For it is not so much the number of unfortunates killed and maimed in the late war, nor again the need for replenishing the world's depleted stores that is responsible for the labor shortage, as it is the question of higher standards of living demanded by workingmen the world over.

So it has come about that workmen, who a few decades ago looked upon all machinery as evil competitors that were being introduced for the purpose of taking that much of their livelihood away from them, are now insisting on the use of machinery wherever possible. This spirit is on the increase. Laborers today resent doing work by hand that can be done by machinery to better advantage; for they realize that better and bigger production must mean an all-round rise in the standards of living.

The era of quantity production is already well under way, but more may be expected of it as the years go by. With labor co-operating in the development and introduction of such processes and machinery, we shall have more labor available for a variety of tasks which today must go unattended through lack of spare hands. Already we have attained high efficiency in many of our leading factories, where the men do not even have to move away from their bench in order to work on thousands of parts and assemblies which come and go from their hands in a steady stream. Automatic conveyors are going to play a tremendous rôle in future industry; we have only begun to make use of these remarkable labor savers. Automatic machinery is still in its infancy, despite our seemingly wonderful attainments. We are doing wonders in drop-forging, casting, and so on.

But where will these products be sold? Will the market not be saturated? Is there not a serious danger of over-production?

It must be remembered that our world—that is, the world with which we do business—is still small. The day is coming when we shall be called upon to provide the Africans and the Asiatics with all manner of useful things, and with the vast populations of those neglected continents as potential buyers of our products, we shall require far greater industries than we have today. Greater production will lead to increased commerce, and we shall have to conduct international trading on a vast scale in order to dispose of our machine-made products. In exchange we shall obtain natural products and other things which are still classed as luxuries because of the limited trade of today. All of which will go far to raise the standards of living throughout the world.

There is only one threat in the way of industrial progress, and that is fuel shortage. Coal is becoming less plentiful, as the decades go by. Oil is becoming scarcer. The future will have to call into play a number of substitutes for these staples of our present life. It may be that alcohol will prove the best fuel to carry on the world's business, for alcohol can be made from a variety of inexpensive ingredients by a simple process. It has been pointed out that an almost unlimited supply of alcohol is available in the tropical jungles, where the prolific vegetation can readily be treated if suitable alcohol-producing plants are conventiently installed. Then there are the water power resources to help out.

Industrial progress must continue, and its future is larger and better than the present. Our problems of today are but those of a transitory period, which, when gradually solved, must lead to better conditions for manufacturer, workingman, and consumer alike.

# Seventy-Five Years of Invention

## A Record of Progress Decade by Decade

### 1845–1855

IN 1846 Richard Marsh Hoe made valuable contributions to printing machinery. He developed the type revolving press of the period in which a single form of type was carried beneath four, six, eight, or ten printing cylinders and used to print upon a sheet borne by each. Later Stephen Tucker converted this into the perfecting press (one that printed on both sides of the sheet). Eventually he adapted his machine to print upon a web or endless sheet of paper.

Of the improvements in civil engineering that deserve to be noted, it must be mentioned that in 1846 the French engineer Fauvelle invented the process of boring by forcing water under high pressure into a hollow boring tool. In 1852 Merriweather, a California miner, invented the hydraulic system of mining gold.

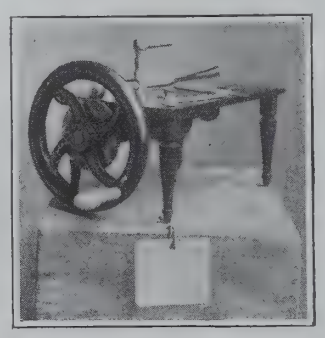
The modern bicycle seems to have had its origin in 1854. P. H. Fischer, a mechanic of Schweinfurt, Germany, added pedal cranks to the velocipede. Ernest Michaux hit upon the same idea in 1855.

In steam engineering the most notable achievement was undoubtedly George H. Corliss's invention, in 1848, of his famous valve gear, patented in 1849. The first steam boiler with horizontal iron tubes was constructed in 1855 by Julien Belleville. Wilcox built his first steam water-tube boiler with inclined water tubes in the same year. In the year 1840 Henry R. Worthington conceived the idea of applying steam to the propulsion of canal boats and in that connection invented the independent single direct-action boiler steam pump—beginning manufacture in 1845.

This decade marks the beginning of the high explosive industry; in 1845 Christian Friedrich Schoenbein discovered guncotton.

Industrially, by far the most important invention of the decade was the Bessemer process of making steel, *i. e.*, the direct conversion of molten cast iron into steel by blowing air into the molten mass. Henry Bessemer invented the process in 1855.

During this decade Stephen Fitch furnished a screw cutting lathe with a number of tools set in a holder which could be revolved to bring them successively to the work. This was the first turret lathe. In 1855 the Jones and Samson Machine Company produced a turret lathe in which the turret was turned automatically. The milling machine, originally invented by Eli Whitney, of cotton gin fame, in 1815, was further developed in 1853 by Frederick W. Howe, and this was followed in 1854 by what has since been known as the Lincoln miller, designed by F. A. Pratt of the Pratt & Whitney Company.



**Sewing machine patented by A. B. Wilson in 1850**

On September 10, 1846, Elias Howe received a patent for his epoch-making sewing machine. The features that made Howe's machine a success were a needle with the eye at the point, a shuttle operating beneath the cloth to form the lock stitch, and an automatic feed. To Allen B. Wilson we are indebted for the rotating hook and the four-motion feed. His first machine was built during the spring of 1849. In the same year he built a second and better machine which he brought to New York in order that he could exhibit it to the Editor of the SCIENTIFIC AMERICAN. In 1851 Wilson patented his famous rotating hook, which performs the functions of a shuttle by seizing the upper thread and throwing its loop over a circular bobbin containing the under thread. In 1859 Gibbs, a Virginia farmer, saw in the SCIENTIFIC AMERICAN a picture of a sewing machine. The working of the apparatus was very plain down to the moment when the needle perforates the cloth, and he fell into the habit of musing upon the course of events after the point of the needle was lost to view. The result of his cogitations, aided by infinite whittling, was the ingenious little revolving hook, which constitutes the peculiarity of the Willcox & Gibbs machine. In 1851 Isaac Merritt Singer brought into the business a new machine. The novelties consisted in the circular feed wheel below the cloth plate, which had a serrated periphery projecting slightly above the plate, and was fed by a rock shaft and pawl; a thread controller; and the use of gear wheels and shafting to transmit the power from the hand wheel to the two countershafts for working the vertical needle and the shuttle. Singer was also the first to introduce foot power in place of the hand-driven crank wheel. John Brooks Nichols, a Lynn shoemaker, about the year 1851 adapted the Howe sewing machine to sew the uppers of shoes.

The first power elevator was installed in 1852 by Elisha Graves Otis; and a few years later he exhibited at the Crystal Palace, in New York, the first elevator with a safety device to prevent the car from falling when the cable broke. The first exclusive passenger elevator operated by steam was installed in the Fifth Avenue Hotel in 1859 by Otis Tufts.

The efforts of inventors to produce a telegraphic printing machine gave impetus to the idea of a writing machine. In 1843, Charles Thurber of Worcester, Mass., patented a slow typewriter. The model was interesting as effecting the letter spacing by longitudinal motion of a platen—a principle which is a feature of all modern machines. In 1847 Dr. Francis patented a typewriter in which a motion similar to that of a piano hammer was employed to throw up the types, which were arranged in a circle, thus bringing them to a common center.

**Reciprocating bar motor of Joseph Henry, patented in 1831**

In 1831 Cyrus H. McCormick of Virginia built the first practical grain harvesting machine. But it was not until 1845, the year in which the SCIENTIFIC AMERICAN was established, that the reaper was really introduced. It contained the essential elements that have been found in every grain harvester that has proved a success from that day to this. The most important feature was the sickle consisting of a bar with projecting fingers through which a knife reciprocated. The grain, forced to the sickle by a reel, was cut and dropped upon a platform. A man, walking alongside the platform, removed the grain with a rake. The next improvement was the addition of a seat for the man who raked the grain. In 1849 Jacob J. and Henry F. Mann patented a machine having a series of endless bands for carrying the grain, after it had been cut and reeled upon these bands, to the side of the machine, where it accumulated in a receptacle until a sufficient amount had been gathered to form a bundle, when the operator dumped the receptacle, leaving the gavel upon the ground. In 1850 Homer Atkins invented a device for giving a reciprocating, intermittent motion to a rake, in order to deposit the grain upon the ground, after it had been cut and reeled upon the platform. In the summer of 1850 Augustus Adams and J. T. Gifford of Elgin, Ill., built probably the first hand binding harvesting machine.

### 1855–1865

The decade is notable for the important work done in laying the foundation of modern electrical engineering. The direct current motor, and the storage battery belong to this period.

The first modern coke oven of the by-product recovery type was built in 1856 by Carvès at Lebrun, Commentry. The principle of centrifugal casting in the production of iron and steel, although proposed as early as 1839, was practically carried out by Henry Bessemer in 1856.

The first modern hydraulic press was built in 1858 by Robinson and Gotham for iron works, but hydraulic press forging was substituted for the hammer in 1861 by John Haswell. Haswell's press was improved by Reiner Daelen in 1865 by applying steam pressure directly, thus dispensing with a pump and an accumulator.

Most important in its general industrial effect was the invention of the regenerative gas furnace by Friedrich and William Siemens in 1856.

On August 28th, 1859, G. L. Drake, while driving an artesian well struck oil. The first really successful pipe line was laid by Samuel Van Sycle in 1865 between Pithole and Miller's Farm.

The modern ammonia absorption ice machine was devised in 1860 by the French engineer, F. P. E. Carre. Improved by Reis (1870) and by Koch and Haberland (1871), this machine held its own until the compression apparatus was brought to a high state of efficiency. A closed cold-air or refrigerating machine was built in 1862 by A. C. Kirck.

Finding that his early pump lacked smoothness in operation, Worthington developed the duplex pump, which he patented in 1859. Another inventor who did much to improve the pump was George F. Blake. In 1862 he installed and operated his first single direct-action pump. In the same period belongs the development of the Knowles pump. In 1863 Holly constructed the first water-works plant in Lockport, N. Y., consisting of a rotary pump, turbine water wheel, about one mile of water main and twelve fire hydrants.

In steam engineering we must note that in 1858 John Elder combined the compound steam engine with the surface condenser, and thus devised a type of double-expansion compound engine, which has markedly influenced the development of marine engineering.

In 1860 Lenoir patented his historic gas engine, in which he actually used electrical ignition.

In 1861 Joseph R. Brown developed the universal milling machine. Cylindrical grinding began in this decade and in 1864 a grinding machine was put on the market by the Brown and Sharpe Company.

The decade brought forth the Solvay soda process, invented by the Belgian chemist and engineer, Ernest Solvay.

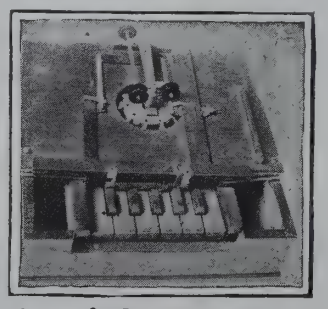
The type revolving printing press was in general use until Bullock introduced his stereotype perfecting press in this decade. This cut the sheets from a web before they went to the printing cylinders. Between 1862 and 1864 Andrew Campbell put out the first cheap cylinder press. Campbell then built his two-revolution printing machine (1865-1870), which has since become the standard press throughout the world.

In 1857 Snell and Bartlett patented their mechanical let-off for warps, an important improvement in textile machinery. The principle of this warp let-off was to actuate the large warp beam containing the warps at the rear of the loom by a ratchet and pawl connection with the oscillating lay, the movement of this ratchet and pawl-actuating mechanism being controlled by the tension of the warps.

It was in this decade that George Pullman introduced the Pullman car. In 1867 he devised the combined drawing-room car, which could be converted into a sleeper at night.

Bushnell in 1775 built the first practical submarine boat, and Fulton in 1801 employed the usual vertical rudder and a horizontal rudder. Although Bauer, a Bavarian, constructed a submarine vessel in 1850, no substantial advance was made until Bougeois and Brun completed "Le Plongeur" in 1864.

The year 1858 marks the beginning of the wonderful modern shoe machine industry, for then it was that Lyman R. Blake invented a machine which sewed the soles of shoes to the uppers. In 1862 Auguste Destouy invented a machine with a curved needle to sew turn shoes, which was improved by Daniel Mills in 1869. This machine was adapted by Charles Goodyear to the sewing of welts. Goodyear patented his machine in 1871 and 1875.



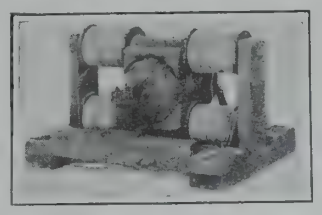
**One of the pioneer typewriters, patented in 1868**

A marked advance in typewriting machines was made in 1856 by Mr. Alfred Ely Beach, Editor of the SCIENTIFIC AMERICAN and one of the founders of Munn & Co. This machine was primarily intended for the printing of embossed letters for the blind, but could also be adapted to the general uses of the typewriter. During the winter of 1866-1867 C. Latham Sholes, a printer and editor by trade, and Samuel W. Soulé, also a printer, inventor and farmer, were engaged together in developing a machine for serially numbering the pages of blankbooks. Carlos Glidden became interested in Soulé's machine and suggested the idea of devising a mechanism which would write letters and words. In the following year a copy of the SCIENTIFIC AMERICAN fell into the hands of Glidden. It described a machine called the pterotype (winged type), invented by John Pratt, which was designed to do just what Glidden had suggested. This article was brought to the attention of Sholes. Glidden, Soulé, and Sholes eventually formed a combination to

develop a practical machine. By September of that year the first machine had been made. James Densmore of Meadville, Pa., was attracted to the new enterprise and purchased an interest in it. He urged further improvements, pointing out many defects. Soulé and Glidden dropped out of the enterprise and left it entirely to Sholes and Densmore. By 1873 the machine had been developed so far that it was felt it could be manufactured, and with that end in view Densmore came, in 1873, to the gun factory of E. Remington & Sons of Ilion, N. Y. At the factory of the Remingtons the machine was further developed and was finally placed upon the market about the middle of 1874.

### 1865–1875

Modern electrical engineering is placed on a sure footing in this decade; for we find not only the dynamo and the motor vastly improved, but new applications of the electrical current made on every side.



**Early type of dynamo for supply current to arc lamps**

Sylvanus D. Locke, in 1873, after associating himself with Walter A. Wood, built and sold probably the first automatic self-binding harvester that was ever put upon the market. The use of wire as a binding material met with opposition, and the inventors turned their attention to perfecting an attachment that would bind with cord; and to Marquis L. Gorham of Rockford, Ill., who built a successful cord binder and had it at work in the harvest field in 1874, must be given the credit of producing the first successful automatic self-sizing binder.

Jacob Reese, an American inventor, in 1875, built a machine for cutting iron and steel with rapidly rotating disks of soft iron. In 1872 A. Brandon developed a file-making machine, which, in imitation of hand labor, applied chisel and hammer separately. However, it could be used only for making flat files. It was improved by Maurice Mondon of London, in 1874, so that convex filing surfaces could be made. The modern machine, however, was invented by Disston of Philadelphia. The idea of rolling instead of forging files was carried out in 1864 by B. H. Dodge, who constructed a machine for that purpose. In 1866 William Sellers and Company developed an automatic machine for cutting gears which operated on the formed tool system. The first commercial automatic machine, however, was produced by Brown and Sharpe in 1877.

George Bedson of Manchester in 1867 invented a continuous wire rolling mill. He was the first to roll out metal bars weighing one hundred pounds into wire at the rate of eleven tons a day.

Railroading received a great impetus by George Westinghouse's invention of the air brake.

An invention which attracted but little attention at the time, but which was the beginning of the reinforced concrete industry appeared in 1867. Then it was that Jose Monier patented a method of making flower pots out of cement with a reinforcement of iron netting.

Benjamin C. Tilghman invented the sand blast in 1871 for producing mat glass. His invention was afterward introduced into the iron and stone industries. Tilghman is also to be credited with the invention of chemical wood pulp. After he had pointed the way, George Fry and his collaborator, Ekman, developed at Bergvick, Sweden, the process of separating the cellulose of wood by boiling it under pressure in an aqueous solution of sulfur dioxide in which magnesium sulfite was dissolved.

In 1862 Joseph Moore of San Francisco brought out the California stamp mill, which became of great importance in mining. The dry concentrator in which air is employed for the separation of minerals was introduced in 1868 by Stephen R. Krom. Another improvement was Dingey's mineral mill (1872) consisting of a slowly revolving horizontal slotted plate over which four notched disks rotated in the opposite direction.

A rotary knitting machine was built by Lamb of Valparaiso, Indiana, in 1866. This machine was afterward improved by Dubied and Watteville. It made a stocking without any seam whatever.

The first great modern vacuum ice machine was exhibited by Edward Carré at the Paris Exposition of 1867. In this machine water was used as the vaporizing fluid and concentrated sulfuric acid as the absorbing fluid.

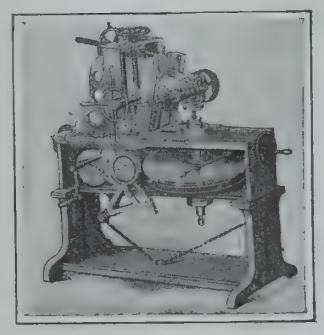
In 1873 Lowe and White invented the modern water gas process. Another improvement in the art of illumination was that of C. Tessié du Motay, who invented the zircon light in 1867, in which a pencil of zircon was heated to incandescence in a gas blowpipe. Clammond, in 1872, hit upon the idea of bringing magnesia to incandescence in a blowpipe. In a sense he was the forerunner of Welsbach.

J. S. Hyatt discovered in 1869 that camphor is a solvent for various kinds of nitrocellulose and thus established the great modern celluloid industry.

Dynamite was invented in 1867 by Alfred Nobel. He discovered the extraordinary absorptive powers of the infusorial earths for nitroglycerine.

Madison improved the bicycle in 1867 by providing it with radial wire spokes.

On September 5th, 1865, Alfred Ely Beach, Editor of the SCIENTIFIC AMERICAN, patented a plan for conveying letters and parcels by mechanical means directly to a central post office from a lamp-post letter-box. In the following year he learned of the success of experimental pneumatic tubes in Great Britain, through which small cars carrying merchandise and persons in a sitting position were successfully operated. Thereupon he invented a plan of dispatching letters pneumatically. X-shaped revolvable valves in lamp-posts were intended to catch the letters as they were dropped from above, and to hold them until the pneumatic car came along, into which they were emptied automatically. A pneumatic subway under Broadway was the next development, the modern tunneling shield, suggested as early as 1824 by Brunel, being practically applied. The shield was pushed forward in a modern way by a series of hydraulic rams, which system Mr. Beach patented June 8th, 1869. With this shield a tunnel was driven under Broadway from Warren Street to Murray Street. A car was propelled through this tunnel by means of a blower, the blower being reversed so as to suck the car back when it had reached the end of its travel.



**Pioneer gear-cutting machine of Joseph R. Brown, 1885**

Almost simultaneously with the steam elevator appeared the hydraulic elevator, which in its simplest form was a ram located under the carrying platform, which was moved up and down by water under pressure, working in a closed cylinder. This system of operation was first put into practical use in 1872. Following this type came the geared hydraulic, in which the ram became a piston, which was attached to the moving element of a system of multiplying sheaves, over which the elevator cables were passed, thus enabling a short cylinder to effect a high lift.

### 1875–1885

This was primarily a decade of electrical invention. Edison's incandescent lamp and Bell's telephone were the outstanding inventions of the period.

In 1877 the phonograph appeared, one of Edison's most original and brilliant inventions. Its first public demonstration was in the office of the SCIENTIFIC AMERICAN toward the end of the same year.

Copyright, Harris & Ewing

**Recording the voice of the American Indian for posterity**

In 1883 Sir Hiram Maxim invented his automatic (self-loading) machine gun, in which he utilized the force of the recoil to reload the weapon as well as to fire it automatically. Most modern machine guns have been based upon this early weapon of Maxim's.

Andrew Campbell in 1875 developed a press which used curved stereotype plates and printed on both sides of the web itself. Later Campbell added a folding machine. Next he built a double printing machine, each half of which contributed a perfected web to a folding machine common to both, whereby he was able to turn out an eight-page paper. Stephen D. Tucker, an inventor in the employe of Hoe, also invented a folder. He applied for a patent (1875); Campbell did not. Hence, one of the most valuable improvements in printing presses fell to the Hoes. At about the same time Tucker invented the collecting cylinder, by means of which the product of one circumferential half of a printing cylinder may be transposed upon the product of the following half, and thus the two brought together as a single product. Two Englishmen, Anthony and Rose, conceived the idea of splitting a web of paper into two longitudinal halves and transferring one-half over and upon the other by means of deflecting bars, so that the right-hand product of a printing cylinder could be superposed upon its left-hand product and the two made up into one. This invention is now included in all double-width newspaper printing presses. Another improvement came when Ford patented a means for running the product of two printing machines into one folding machine. Crowell, an ingenious Yankee skipper, invented the longitudinal folder, by which a web may be folded longitudinally while on the run and still in web form. About the same time (1879-1889) he conceived the idea of the rotary fly. This was the last device necessary to the creation of a 24,000-copies-an-hour printing press, and when it was introduced (in the early eighties) the rotary newspaper printing press in all its elements became the machine it is today.

The universal grinder which has been in process of development for a number of years at the hands of Joseph R. Brown was exhibited at the Centennial Exposition. The generating system of gear cutting was invented by Hugo Bilgram in 1881.

Important progress in metallurgy was made. After M. J. Holway had made experiments in bessemerizing copper (1877-1878), following the experiments of Semennikow, M. J. Brown of Sheffield succeeded in blowing Rio Tinto ores in Bessemer converters. The modern Otto by-product coke oven, an improvement on that of Bauer and Hoffmann, was introduced in 1880. Alexander and MacGosh invented the so-called Gartsherrie process for obtaining ammonia and tar from blast furnace gases.

The first two-cycle gas engine appeared in 1879. It was the invention of Clerk and was distinguished by its separate compression pump, which charged the working chamber and also acted as a scavenger. The first gas engine for locomotives was built in the same year by Marcel Deprez. The gas was compressed in a suitable container, and after having been allowed to work expansively like steam, was mixed with air, exploded, and thus made to do work again. In 1880 the French engineer, Serpollet, constructed a steam engine for tram cars employing a flash boiler. But the crowning invention in engines was the steam turbine. In 1884 Charles Algernon Parsons of Newcastle-on-the-Tyne invented his multi-cellular turbine, which utilizes steam first on the action and then on the reaction principle.

In the same year Pelton, an American, invented the Pelton wheel, in which cups are used instead of blades, the cups being so designed that they utilize the force of the impinging water to the utmost limit of possibility.

For many decades inventors had endeavored to supply a satisfactory machine for setting type. It was not until 1888 that such a machine was invented. It was the invention of Ottmar Mergenthaler, and it worked on an entirely new principle. Instead of setting the types and after their use distributing them among their respective receptacles, Mergenthaler employed the type-matrices, and from these cast, as a single piece, a line of characters. Hence, his machine was called a "linotype." On the heels of the linotype came another device—the "monotype," invented by Lanston. This monotype consisted of two independent mechanisms, the one a keyboard by means of which the operator was enabled rapidly to perforate a paper ribbon with holes which represent characters, and the other a type-casting mechanism controlled by the perforated ribbon.

The first really successful modern volatile hydrocarbon automobile had its origin in this decade, as described elsewhere in this issue.

In 1876 J. P. Holland built a submarine vessel (the "Fenian Ram"), following the Fulton system of control by vertical and horizontal rudders. She was fitted with an air gun which could be discharged under water, and was probably the first submarine torpedo boat, if we give the word torpedo its largest significance.

In 1880 Alexander E. Brown installed the first mechanical ore unloader to take ore from the hold of a boat and deliver it either to cars or to stock piles without rehandling.

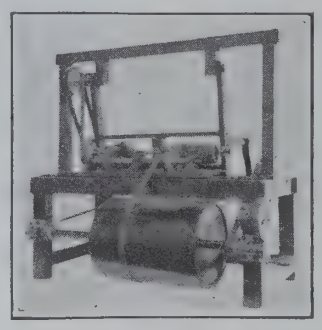
During this period the Ekman paper-pulp process was markedly developed. Mechanical difficulties surrounded the operation from the start, though the quality of pulp produced was excellent. The digesters in which the wood was cooked were lined with lead and the heat developed in the acid liquor proved to be exceedingly disturbing, as while the lead expanded during the application of heat, it did not contract again

when cold. The difficulty was overcome by the invention of a digester lining composed of heavy cement backing, faced with brick, the latter being pointed with litharge and glycerin.

Perhaps the most important invention in pulp-making processes, especially in view of recent work in the utilization of waste wood, dates from 1883, when Dahl introduced the sulfate process for the treatment of straw, a modification of which is now applied to the production of pulp from coniferous woods that are not amenable to other treatment.

### 1885–1895

The turret lathe with flat style of turret was invented by James Hartness in 1889 and was further improved in 1891. In 1894 Conrad M. Conradson invented a lathe with hollow spindle through which the work could be fed to the machine.



**Blanchard duplicating lathe built in 1843**

The year 1893 marks the publication of Rudolf Diesel's "Theory and Construction of a Rational Heat Motor," in which he set forth the principles of the well-known Diesel engine. In 1887 Gustaf de Laval invented his high-speed steam turbine, in which the potential energy of the high-pressure steam is transformed into kinetic energy in a single stage and imparted to the shaft. In the same year he designed his centrifugal cream separator, which ever since has been widely used throughout the dairy industry.

In 1894 Bénier patented the suction producer-gas plant in which the motor is made to draw its gas from the generator, thus producing a depression in the generator which is filled by air below atmospheric pressure. This air is mixed with steam and forms new gas in passing over the layer of glowing fuel.

The first attempt to use compressed illuminating gas was made by Julius Pintsch in 1891. His system, properly developed, made it possible to illuminate railway trains with gas.

The famous McArthur-Forrest cyanide process, which has been of immense importance in gold mining, was brought out in 1887 by Robert William Forrest, William Forrest, and John McArthur. These investigators found that the effect of potassium cyanide depends upon the weakness of the solution. The gold mines of the Transvaal took up the process almost as soon as it was introduced.

The possibilities of the electrical furnace were never before so brilliantly revealed as in this decade. In 1862 Woehler discovered that water acting on calcium carbide would produce acetylene. The next step was to make calcium carbide cheaply. An early attempt with the electric furnace was that of Henri Moissan (1892), who succeeded in making calcium carbide out of marble and sugar carbon. Then came Thomas L. Willson, to whom the credit is really due of placing the manufacture of calcium carbide upon an industrial basis, which he achieved in 1892 in coöperation with Dickerson. Paul Héroult constructed the cathode furnace (1887) for uninterrupted operation and thus becomes the founder of the electrometallurgy of aluminum according to the smelting method. Edward G. Acheson succeeded in 1892 in making silicon carbide in the electric furnace—an abrasive which has been known to the trade as carborundum. He also obtained artificial graphite in the electric furnace for the first time.

The first commercially successful process for making artificial silk was that brought out in 1885 by Chardonnet, who squirted nitro-cellulose under pressure through small holes in water, alcohol, chloroform or the like, the threads congealing at once.

John B. Dunlop, a dentist of Dublin, Ireland, invented the pneumatic tire in 1890, as we know it today. He seems to have been quite unaware of Thomson's pioneer work in the same line (1846).

Edison's experimental success with his tinfoil phonograph in 1877 proved the starting point of much valuable investigation in sound production by himself and others. In 1886 Dr. Chichester Bell and Charles Sumner Tainter patented their method of recording and reproducing sounds by engraving a wax or wax-like substance, thus producing records that could be removed from the machine, handled and transported. In 1887, Emile Berliner invented the gramophone or disk graphophone and worked out for practical use the system of duplicating disk records, which has been in use ever since.

Goubet of France built several submarine torpedo boats between 1885 and 1890. The novel feature was his propeller, which worked on a universal joint so that it could be changed as to the direction of thrust. It took the place of vertical and horizontal rudders. Prof. Josiah Tuck carried on experiments with his submarine ("Peacemaker") in the Hudson River in 1885, using caustic soda to generate steam. His boat had a water lock through which a man, clad in a diving suit, could pass. Several other submarines were built in Europe during this period. The most successful of these was perhaps the "Gymnote" built in France after the designs of Dupuy de Lome and Gustave Zédé.

In 1893 the United States Navy advertised for bids for the construction of a submarine. J. P. Holland, George C. Baker, and Simon Lake handed in plans. Baker's design was based on the performance of a vessel he had experimented with in 1892. Holland submitted plans for a steam vessel of the diving type with horizontal rudders at the stern for changing the inclination of the vessel, as first used by Fulton. Lake submitted a design for a vessel with an inner and outer hull, the inner space to be utilized for water ballast. This vessel was designed to be operated submerged on a level keel by the use of hydroplanes; bottom wheels were provided to enable the vessel to be navigated on the water bed itself; air locks were called for to enable the crew to escape in case of danger. Holland secured the Government award because of his previous experience. His vessel, the "Plunger," was not a success, due to her enormous steam installation, which made the interior of the boat unbearably hot, and to her lack of stability. Lake's idea of running along the bottom on wheels—an entirely new conception in the art—received its first demonstration in 1894. This craft was the germ from which later emerged his "Argonaut" (1896-1897), the first submarine to be fitted with an internal combustion engine.

### 1895–1905

This is the decade of the airplane and the airship and of wireless telegraphy, all of which are described elsewhere in this issue.

A vertical turret lathe appeared in 1901. This was the invention of E. P. Bullard. The Bilgram gear-cutting machine was improved in 1898 by J. E. Gleason. The most important development in the field of machine tools was the invention of high-speed steels by Frederick W. Taylor and his associates which made possible heavier cuts and higher cutting speeds.

In 1897 Hans Goldschmidt of Essen invented the well-known thermit process. Thermit, however, was not introduced commercially until 1899. The modern process of autogenous welding was introduced in 1905 by Fouché, oxygen and acetylene being used in a specially constructed blowpipe.

An attempt to reduce nitrogen from the air electrically was made in Niagara Falls by Bradley and Lovejoy in 1900. This experiment, while not commercially successful, at least served to inspire later work. Thus Christian A. Birkeland and Samuel Eyde built their Norwegian plant in 1903, using electric arcs spread out by magnets so as to obtain a great heating surface.

The steam turbine was markedly developed during this period. C. G. Curtis invented in 1896 his multi-stage pressure turbine. A. Rateau in 1898 constructed his multi-stage pressure turbine. Zoelly in 1902 constructed a multi-stage pressure turbine which is essentially similar in principle to that of Rateau. A. Rateau invented the first turbo-compressor in 1900 and a turbo-pump in 1902.

The principle of utilizing internal work in liquefying air as well as the counter-current principle of refrigeration was discovered in 1898 by Karl P. G. Linde. The outgoing air was used to cool off the air still contained within the apparatus so as to produce a cumulative refrigerative effect. He built a refrigerating machine on this principle with which very low temperatures were reached.

In 1898 Ochelhäuser of Dessau installed an engine in the Hörde Iron Works for the utilization of blast furnace gases; the engine itself was patented in 1896, and was a two-cycle double piston engine. The Körting blast furnace gas engine was brought out in 1898. Cockerill of Seraing, Belgium, introduced a four-cycle blast furnace gas engine in 1899. From this the two-cylinder blast furnace gas engine of the Nürnberger Maschinenbau Aktiengesellschaft was shortly evolved.

In 1904 James A. Gailey brought out his dry blast process for the production of iron and steel. He solved the problem of drying the air by freezing out the water.

The American iron industry suffered a great change in this decade. The Mesaba ores were being introduced. Since the blast furnaces were far removed from the Lake Superior beds cheap handling was an essential, a consideration met by Brown's bridge cranes, cableways, and trolleys. A radical departure was made in ore handling when G. H. Hulett in 1898 invented the automatic ore unloader bearing his name.

In 1897 Karl Engler made exhaustive researches on the decomposition of hydrocarbons when subjected to heat and pressure. Thanks to him much light was shed upon chemical reactions, which take place when oil is cracked. Most cracking processes are based upon the methods disclosed in patents taken out in 1890 by Dewar and Redwood. The Dewar and Redwood process is in turn an outgrowth of the Krey high-pressure distillation process of 1887.

The method of hydrogenating soft fats and oils, whereby it is possible to convert vegetable oils into substitutes of lard and some fats into hard fats of greater commercial value was discovered in 1902 by P. Sabatier and J. B. Senderens.

The separation of ores by oils was introduced in 1902 by W. Elmore. The ground ore mixed with the residue of petroleum distillation was placed in rotating cylinders so that oil and pyrites are intimately mixed. The oil was then centrifugally separated.

In 1899 William Draper constructed a loom with automatic shuttle-changing mechanism, the first practical success of its type, and the result of ten years' experimenting. The present type of automatic bobbin-changing loom was the outgrowth of an invention made by James H. Northrop, who conceived the idea of changing the bobbin in the shuttle automatically while the loom was in motion. On June 23rd, 1891, Rhoades received a patent for shuttle-changing mechanism, which applied the principle of the weft fork for detection of the absence or the failure of filling and of an ejector to the changing of a shuttle in which the filling was exhausted. An early patent for automatic weft-replenishing looms, especially adapted for multi-colored weaving, was granted to Wyman and Crompton in 1898.

After Campbell, Tucker and Crowell had brought the newspaper printing press to a point where 24,000 to 29,000 copies could be printed an hour, no marked improvement was made until Henry Wise Wood introduced radically new ideas. Instead of drawing the paper through the press—a proceeding which subjected it to strain and reduced the speed of printing for fear of breakage, Wood carried it along bodily without strain to the printing types. The machine adjusts itself automatically to the peculiarities of the various paper rolls, so that breakages are avoided and the amount of attention required by the press is reduced to a minimum. The paper is handled in streams and assembled in a single stream made up of as many thicknesses as the newspaper to be printed has leaves. This combined stream is then folded, cut and delivered at the rate of 60,000 an hour (eighteen to thirty-two pages).

### 1905–1915

In 1900 stereotyping was revolutionized by the introduction of Henry Wise Wood's "Autoplate" machine. This consists of a casting mechanism and a series of finishing mechanisms which automatically coöperate in one machine to make casts and finish them. When used to make plates of the conventional half-inch thickness its speed is four finished plates a minute; but when the thickness is but one quarter of an inch eight plates a minute are easily obtained.

In the field of machine tools the decade is marked by important improvements in gear cutting machines of the generating type. J. E. Gleason obtained patents in 1907 and 1910 and E. R. Fellows in 1907, 1908, 1911 and 1912.

One of the notable developments of the decade was the use of the gyroscope in a great many widely different applications. Mr. Louis Brennan, inventor of the Brennan torpedo, devised a gyroscopic monorail. This renewed interest in the previous invention of Schlick, who used a gyroscope to keep a ship from rocking. Dr. H. Anschütz-Kämpfe developed a gyroscopic compass to displace the magnetic compass, and this has been used with considerable success in warships, particu-

larly submarines in which the compass is entirely surrounded by a steel shell that acts as a shield for the magnetic needle and prevents it from being affected by the earth's magnetism. A gyroscopic stabilizer for airplanes was developed by Sperry in this country.

A process of dry galvanizing or "sherardizing" was discovered by Mr. Sherard Cowper-Coles. By this process iron and zinc can be coated with metallic zinc by the simple operation of bedding the piece in zinc dust in a drum and raising the temperature of the zinc dust to 500 or 600 deg. Fahr., which is some 100 degrees below the melting point of zinc. Dr. Schoop of Zürich invented a method of coating objects with metal in which the metal in pulverized state was projected against the object by a jet of high-pressure steam.

In 1907 E. G. Acheson discovered a method of producing deflocculated graphite.

Mr. H. A. Humphrey, a well-known English engineer, invented an internal combustion water pump.

Mr. David Roberts invented the caterpillar tractor which could haul heavy guns or other trailers over rough country.

The decade was particularly marked for developments in illumination, but this subject is fully covered in the special article on electricity.

Early in the decade Parsons of turbine fame brought out his "auxetophone," a device for augmenting talking machine sound reproduction by the use of compressed air, the air being admitted through a valve controlled by the needle, and hence taking the place of the reproducing diaphragm.

Fournier d'Albe invented an apparatus known as the "optophone," which renders light audible.

The closing year of the decade led to much activity in the development of war inventions. The Lewis machine gun invented by Colonel I. N. Lewis of the United States Army was widely used by the British and Belgians. This one-man gun uses part of the gases produced by the firing of the cartridge to furnish the power required to actuate the mechanism and the gun is cooled by air set in motion by the bullet. In 1915, gas warfare was introduced by the Germans.

### 1915–1920

As we come down to the present day it is increasingly difficult to pick out important inventions. Machines and processes that look very promising may turn out to be failures and an obscure invention that might easily be overlooked today may prove to be of epochal importance.

Most of the prominent developments of this period have to do with the war and their value was immediately tested. They are of such recent occurrence and so fresh in the minds of our readers that we need merely list them:

The Browning machine gun and Browning shoulder rifle were developed by John M. Browning after our entry into the war. There were important improvements in large guns, most notable of which was the German 75-mile gun with which Paris was shelled. Trench warfare led to the invention of various types of trench mortars. Gas warfare was highly developed and all manner of poisonous and suffocating gases were discovered and fired in shells by the opposing armies. Battles were carried on at night under the light of flares and star shells. The most notable invention on land was the tank, a development of the caterpillar tractor which was a factor in overcoming machine gun nests.

On the sea the submarine was highly improved. The Germans built a number of mine-laying submarines. To overcome the submarine the depth bomb was invented and the hydrophone was developed by which the presence of a submarine could be detected by sound.

Since the war a very promising development in thermo-dynamics is the Still engine. In this engine the piston is driven in one direction by internal combustion of fuel and in the other direction by steam generated by the combustion in the cylinder. The efficiency of this engine rises as high as 41 per cent, while the highest efficiency of any other prime mover is only 36 per cent, this figure having been attained by a Diesel engine. The inventor is William Joseph Still.

The most remarkable machine of this period is the type reading optophone—an instrument by which the blind can read ordinary print. The inventor is Dr. E. E. Fournier d'Albe. A complete description of this instrument is to be found in the current issue of the SCIENTIFIC AMERICAN MONTHLY.

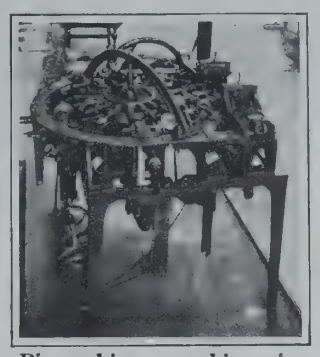
## The Current Issue of the Scientific American Monthly

ON account of the critical paper situation, the SCIENTIFIC AMERICAN MONTHLY was obliged to suspend publication for the months of August and September. Publication, however, is resumed with the October issue and we hope that there will be no further interruptions. The contents of the October number are exceptionally interesting.

One of the most marvelous instruments of the present day is an electrical reader by which the blind are enabled to read any ordinary printed matter. The "type-reading optophone," as it is called, is the invention of Dr. E. E. Fournier d'Albe. The inventor's own description of the machine is given in the current MONTHLY with photographs and diagrams illustrating the operation of the apparatus.

"The World's Supply of Energy" is the title of an exceedingly interesting paper by Dr. Svante Arrhenius, Ph.D., M.D., D.Sc., LL.D., who discusses the problem that we shall have to face when our supplies of coal and oil are exhausted. In this connection, another article entitled "Setting the Tides to Work" will be found of interest.

Dr. Caroline Rumbold, pathologist of the Bureau of Plant Industry, U. S. Department of Agriculture, tells of a new method of giving medicine to trees and shows how the chestnut blight is being fought by injections of curative chemical solutions.



**Pin-making machine invented by John Ireland Howe in 1835**

If America is to hold its place in the commercial world, we must pay more attention than we have in the past to geographic training. This subject is discussed by J. Paul Goode, Professor of Geography in the University of Chicago.

A very important article is one entitled "The Breaking Up of Nitrogen" by Dr. E. Regner, in which he shows how the theory of the transmutation of metals is verified in a startling manner by modern research.

In the March issue of the SCIENTIFIC AMERICAN MONTHLY, there was an account of an ultra rapid cinematograph which would take pictures at the rate of 20,000 to 50,000 photographs per second. In the current issue of the MONTHLY, further information on this subject is given, with actual photographs of the flight of revolver bullets, birdshot from a shotgun and a 37 mm. shell.

Dr. K. Seibel writes on the interference of X-rays, in which the vibratory nature of Roentgen rays is proved by an ingenious experiment.

There is an interesting article on the miniature textile mill of the U. S. Bureau of Standards by Herbert T. Wade.

Altogether there are twenty-six articles in the current MONTHLY, together with a large number of notes and the usual departments of the National Research Council, the Bureau of Standards, Progress in Mechanical Engineering, Mining and Metallurgy, Electricity, Chemistry and General Science.

## Asbestos in America

AN asbestos claim has been located in Apache County, Arizona, according to an authoritaive investigation by the U. S. Bureau of Mines. The deposit, seemingly extensive in its reach, has been traced for more than 20 miles. Vein exposures are so pronounced that the passerby, in the absence of miner's tools, can pick from the wayside a ton or more of the crude product, broken down from the prominent veins.

A specimen of the deposits examined by government scientists revealed characteristics of the typical Arizona asbestos. The material is strong, flexible, silky and found in cross-fiber veins with a grain length of one to one and one-quarter inches, while fiber two and one-half inches in length has been reported. Specimens examined evidence effects of surface weathering, a better quality of asbestos doubtless being obtainable by development work.

Considering the shortage of crude asbestos in this country, it is regrettable that the Government forbids the mining of asbestos deposits on unallotted Indian lands, where this discovery has been made. The Office of Indian Affairs has recommended to Congress the lifting of the ban which now prohibits the development of unallotted Indian lands for the purpose of mining asbestos, coal, oil and gas.

The U. S. Bureau of Mines is in receipt of information from Genoa, Italy, of the manufacture of a new asbestos product. The fresh undertaking is the making of asbestos pipes of 85 per cent Portland cement and 15 per cent asbestos fiber of shingle stock grade. The pipe is constructed in varying sizes, from 4 to 12 inches in diameter and in lengths up to 12 feet. The thickness increases with the size from one-half inch for the 4-inch pipe to 15/16 for the 12-inch size.

Four machines are in operation by this foreign enterprise, each unit having a capacity of 3,000 feet of pipe every 24 hours. The finished product is seasoned under water for 90 days before used. Lighter in weight than iron pipe, among the virtues claimed for the new asbestos product is that it will stand up under a maximum pressure of 450 pounds to the square inch. It is acid-and-corrosive-proof.

Taking into consideration the excessively high cost of Portland cement in Italy, due to the soaring prices of coal, it is claimed that the expense of manufacture is not more than one-third of the net selling price of coal. The same Italian enterprise is likewise making wall tile of similar composition to the asbestos pipe. It is decorated with imitation rock surface patterns and figured designs. Although a better glaze is desirable, the material is attractive, less brittle than porcelain tile, and because of the comparatively cheap cost of production offers an inviting field for development. Owners of the Italian patent desire to grant manufacturing rights for these products to an American firm on a royalty basis. Samples of the tile are on public exhibition at the Bureau of Mines, Washington, D. C.—By *S. R. Winters.*

## A New Process to Improve Steel Making

AN improvement of the acid Bessemer steel process which aims to reduce the cost of making steel and to decrease the possibility of low quality steel in the process has been recently invented by a member of the department of mining and metallurgy at the University of Wisconsin.

The purpose of the invention is to use basic material for the lining of the Bessemer converter instead of the acid lining now used in order to prevent corrosion of the interior of the converter and to reduce the amount of air pressure and engine power now required. With the basic lining, composed of lime, magnesite, dolomite, oxid of iron, or the like the inventor believes it will be possible to use lower pressure and cut down the time of blowing about 30 per cent.

To prevent corrosion of the converter bottom the inventor proposes a number of different kinds of linings for various acid Bessemer converts and details the particular parts of the converter that require such a basic lining, while the remainder of the converter has an acid lining to resist corrosion by the acid slag. The invention is applicable to the bottom-blown type, side-blown type and other kinds of Bessemer converters operating on the principle of making steel by blowing air through a body of molten iron.

## Quake-Proof Houses

EARTHQUAKES in Italy, America, and elsewhere, the great explosion at Silvertown, the alarming subsidences due to brine-pumping at Northwich, and various cases of settlement in unstable soils have sufficiently demonstrated the advantages of the "single-unit" action of the reinforced concrete skeleton system, says a British writer. Now that so much energy is being expended on the design and construction of dwelling-houses, and innumerable schemes are being submitted for approval by enthusiastic patentees, it is well that people about to build on clay soil, especially when the surface is hilly or undulating, should take into consideration the advisability of adopting the reinforced concrete skeleton as a safeguard against future troubles in the form of cracked walls, bay windows, porches and ceilings, constantly recurring damage to plaster cornices and wall paper, and frequent attention to the fit of doors in openings which vary in dimensions with the state of the weather. This is by no means a fancy picture, but fairly represents the effects of clay soil on houses of ordinary construction, the extent of the trouble naturally varying with local conditions. The monolithic reinforced concrete skeleton is a certain preventive of structural dislocations, and if the panels are fitted with brick curtain walls the building will possess all the advantages of one constructed in the ordinary way, without its shortcomings in respect of stability.

# Civil Engineering

## What the Man with the Transit and Level Has Done During the Past Seventy-five Years

IF we were called upon to name the technical profession which more than any other has been concerned with our modern industrial development, it would be safe to name that of civil engineering. For without the man with the transept and the level, it would have been impossible to weave over the continent of the earth its vast network of railways with its crossings of the rivers by bridge or tunnel, its vast retaining walls and embankments and its bold piercing of mountain summits by tunnels. This is said with no disparagement of the mechanical engineer, without whose multiplied activities the work of the civil engineer would have been greatly delayed and even in some cases indefinitely postponed, for his ingenious constructions have been always forthcoming to make possible the work which the civil engineer put through.

**Manhattan Suspension Bridge across the East River. Length of main span, 1,470 ft., width of floor, 120 ft. Capacity: four two-track electric railways; a 35-foot roadway, and two 10-foot sidewalks**

In a brief review of civil engineering during the past seventy-five years. we can do no more than touch lightly on the greater works which have been accomplished, and we shall confine ourselves in this review to the construction of long-span bridges, sub-aqueous tunnels, subways, canals, water supply and irrigation.

### Bridge Engineering

The early development of American bridge engineering shows a wide divergence from that in Europe. When we passed from the wooden bridge to the steel bridge, the eye-bar type of construction quickly beeted construction. Their bridges were more shallow and more rigid, took more time for construction and erection and were more costly. When we came to build in the larger sizes, we turned increasingly to riveted work, with the result that the modern American bridge is a combination of the two systems.

Among early notable bridges, mention should be made of Robert Stephenson's railway bridge over the Menai Straits, the crossing being made up of 8 rectangular plate-iron tubes of which four are 230 feet and four 472 feet in length. Of the same type was the celebrated Victoria Bridge across the St. Lawrence River, of 25 spans, each 244 feet in length.

It is in the construction of long-span suspension bridges that American engineers have won perhaps their greatest distinction. In the year 1855 Roebling built the Niagara suspension bridge of 821 feet span; and in 1874 commenced construction across the East River, New York, of the beautiful Brooklyn suspension bridge, with a main river span of 1,595 feet, which will forever be associated with his name. It is carried upon four 15-inch wire cables, and the work was opened in 1883. In all the world there was nothing approaching this structure in size at the time it was built. In 1902 the Williamsburg suspension bridge over the East river was opened. The central span of the bridge is 1,600 feet. A few years later the Manhattan Bridge with a main span of 1,470 feet and a floor width of 120 feet was put in service. The steel wire cables of this bridge are 20 inches in diameter. It carries, in addition to a main roadway and passenger walks, eight railroad tracks which are laid upon two decks.

After thirty years of waiting for a bridge to cross the North River, it now seems likely that work will be started shortly upon the great railway and vehicle bridge planned by Gustave Lindenthal, and that this structure, by means of suitable sculpture and bronze tablets, will be constituted a memorial to those

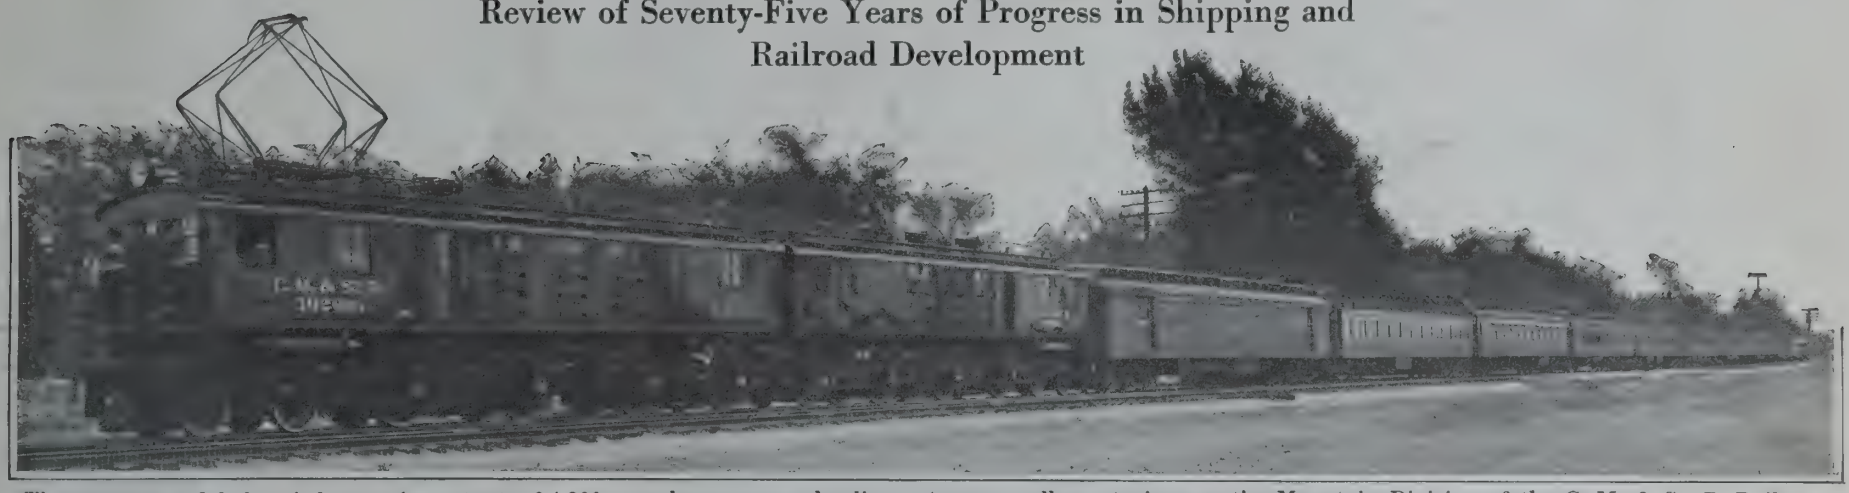
# Transportation by Sea and Land

## Review of Seventy-Five Years of Progress in Shipping and Railroad Development



The most powerful electric locomotive extant, of 4,200 max. horse-power, hauling a ten-car pullman train over the Mountain Division of the C. M. & St. P. Railway

THERE is a sense in which it may be said that the story of human progress is the history of man's struggle to overcome the inertia of things. This is true in the domain of intellect and morals, and it is doubly true of the material world. Who shall set a limit upon the benefits that have come to us from the development of transportation? Can we not truly say that the material advance of civilization is to be measured by the facilities of the human race for travel? Certainly this holds good of the later centuries, particularly of the nineteenth and of the twentieth.

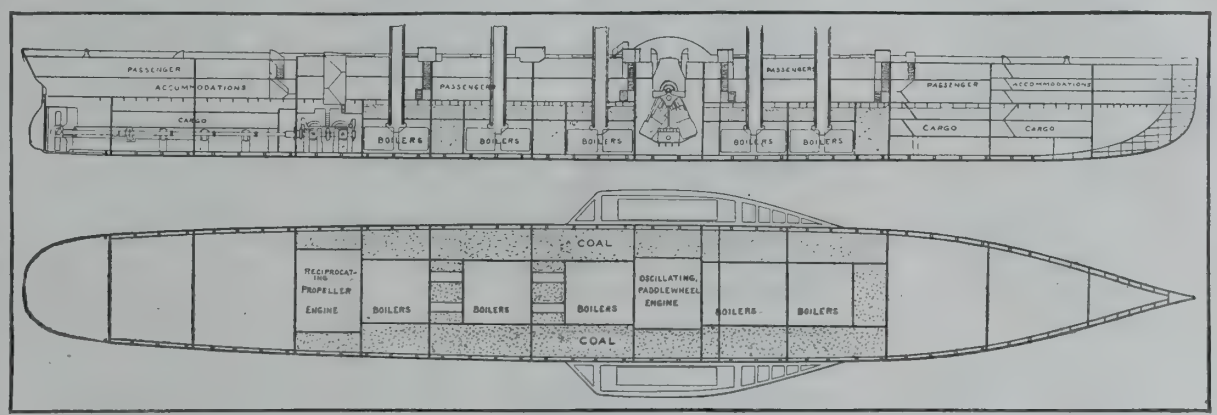
The present review of this subject is concerned with the seventy-five years covered by the unbroken publication of the SCIENTIFIC AMERICAN, and one does not proceed very far in his study of the subject before he realizes that there has been more development of transportation since 1845 than in all previous recorded history. In that early day the steam-driven ship was beginning to be a competitor of the sailing ship.

### The Beginning of Steam Navigation

Twenty-five years before the SCIENTIFIC AMERICAN commenced publication the sailing ship, "Savannah," equipped with auxiliary paddle-wheels which could be taken inboard, had crossed from Savannah, Georgia, to Liverpool in twenty-eight days, having made use of her steam power for about three and one-half days of the voyage. The "Savannah" was an attempt to apply to ocean navigation the work of Symington, whose steamboat, the "Charlotte Dundas," in 1802 had towed two 70-ton vessels successfully for twenty miles on the Forth and Clyde Canal, and the better-known work of Fulton, who in 1807 built the famous steamboat "Clermont," the forerunner of the American river steamer of today which, on its trial, ran a distance of 150 miles in thirty-two hours. Later, in 1833, the "Royal William," propelled entirely by steam power, crossed the Atlantic from Quebec. Then came the "Sirius" and the "Great Western," the latter being the first steamship designed especially for the Atlantic trade. Both of these boats reached New York on April 23d, 1838.

The voyage of the "Sirius" and the "Great Western" proved that transatlantic steamship navigation was thoroughly practical, and several lines that were destined to become famous, such as the Cunard Line, the Inman Line, the Collins, an American line, and the Anchor and the Allan Lines, began their active service.

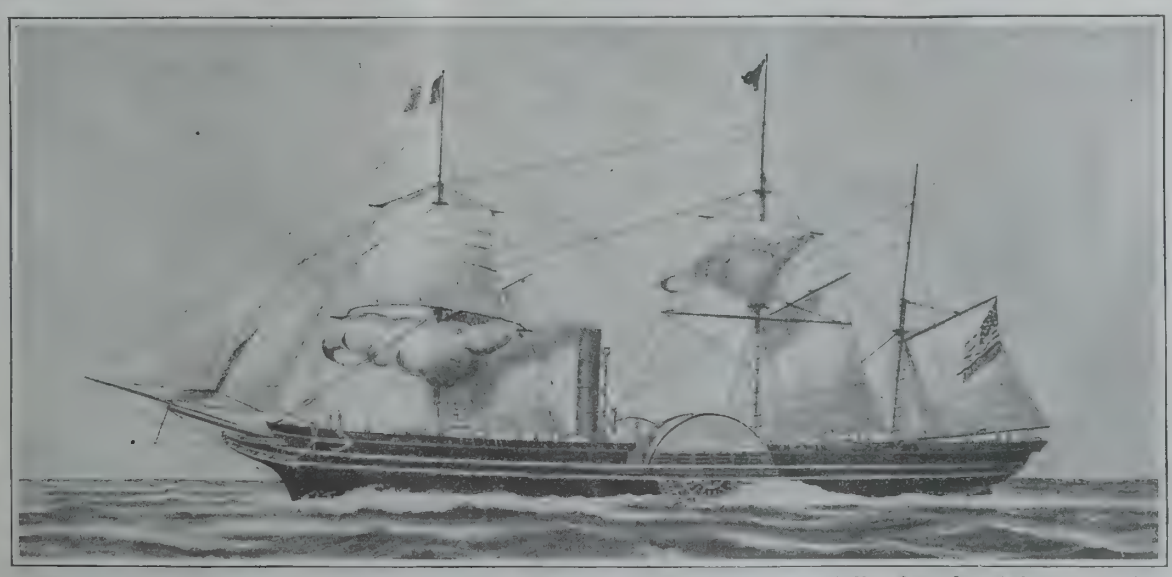
All of these early boats were equipped with side wheels and were driven by side-lever engines, which were practically a modified form of the engine developed by the great Watt. The American vessels used the overhead beam engine, and this was destined for many years to be the characteristic type both for ocean and river service. Steam pressures were very low, running from three to five pounds, and seldom exceeding ten pounds above atmospheric pressure. So bulky were the engines that they occupied nearly one-third of the length of the ship. At about the same time, experimental work was begun by Ericsson in America and by Smith and Woodcroft in England on the introduction of the screw propeller. The first British steamship to use this form of propulsion was the "Archimedes." The British admiralty, after competitive tests between the paddle-wheel and propeller, launched the "Rattler," in 1843. It was so successful that many other screw-driven naval vessels were built.



Longitudinal and horizontal sections throughout the "Great Eastern" (1858), showing the elaborate system of sub-division

Two years before the appearance of the SCIENTIFIC AMERICAN, that great engineer, Brunel, built the "Great Britain," which in size, construction and equipment marked a great advance over contemporary practice. She was 322 feet over all, and was remarkable for being built entirely of iron, with iron masts and wire rigging. Furthermore, she was divided into five, separate, thoroughly water-tight compartments.

The first American steamer to be built especially for the Atlantic trade was the "United States," of 2,000 tons. She was the first merchant steamship constructed for naval use as a cruiser, provision being made for arming her with two tiers of guns. Then came such American ships as the "Washington," of 1,700 tons, the "Hermann," of 1,800 tons, the "Franklin," of 2,400 tons, and the "Hamburg," of 2,850 tons. Conspicuous mention should be made here of the Cunard Line, whose first ship, the "Britannia," one of four built specially for the passenger and mail service, made her maiden trip from Liverpool to Boston in July, 1840. During the decade 1840-1850, the control of the steamship traffic between America and England was practically in the hands of the Cunard Company, and as a result of the inroads which they were making upon the trade of the celebrated American clippers, an American company was formed by Mr. E. K. Collins, of New York, to establish a rival line of American steamers. Four ships, which were intended by their size and speed to surpass the Cunarders, were built with all possible dispatch, and in 1850, the American company had four ships afloat which in speed and comfort were a distinct advance upon anything afloat. These ships, in the year 1851, lowered the time from New York to Liverpool to nine days, twenty hours, and fifteen minutes. The engines were of the side-lever, condensing type, and the boilers carried about seventeen pounds of steam. The best day's run of the "Arctic" was 320 knots at a speed of 14 knots. The Collins venture, opening so auspiciously, was destined to meet with a series of disasters, and these, coupled with the rivalry of the Cunard Company, who, in 1855, launched the "Persia," of fourteen knots' speed, and the withdrawal of the Government subsidy, brought about finally the dissolution of this famous company.



"United States," first American ocean-going steamship. Designed especially for the Atlantic trade

### The Famous Clipper Ship Era

Just here something should be said about the wonderful era of the American clipper ship, which lasted for a quarter of a century or, say, from 1845, when there was a demand for a more rapid delivery of tea from China, down to the opening of the Suez Canal and the coming of the large steam-driven ship. The high premium that was

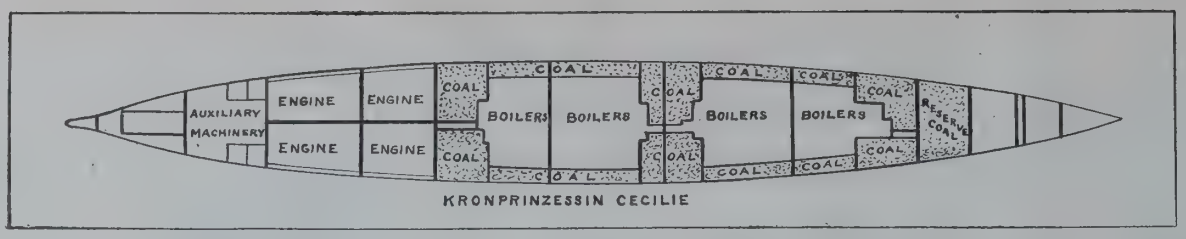
paid for the first consignments of tea led to the building of finely modeled, heavily sparred, square-rigged ships, out of which the Yankee captains got every possible knot of speed. Instead of avoiding these men courted the gales of wind, if they were favorable, and some astonishing day's runs and hourly speeds were attained. These records are authentic and anyone who loves the sea and ships will find it all written down most entertainingly in "The Clipper Ship Era," by Capt. Arthur H. Clark, one of the few survivors of that notable time. Mr. Clark copied these records from the original log books of the skippers, which he found preserved in archives of shipping companies, in museums or elsewhere.

To take one or two instances. The "Flying Cloud," during a passage of 89 days from New York to San Francisco, sailed for four consecutive days 284, 374, 334 and 264 miles—an average speed of 13½ knots. The "Sovereign of the Seas" sailed before heavy westerly gales on four successive days 396, 311, 411 and 360 miles—an average hourly speed for 1,478 miles of 15½ knots. During her great run of 411 miles in a sea day of 23 hours, 18 minutes, she averaged 17 2/3 knots. The highest recorded speed was made by "The Lightning," 244 feet in length, in 1854, during a trip from New York to Liverpool. The log entry for March 1st reads, "Wind south. Strong gales—hove log several times and found ship going through water at rate of 18 to 18½ knots; lee rail under water and rigging slack. Distance run in 24 hours, 436 miles."

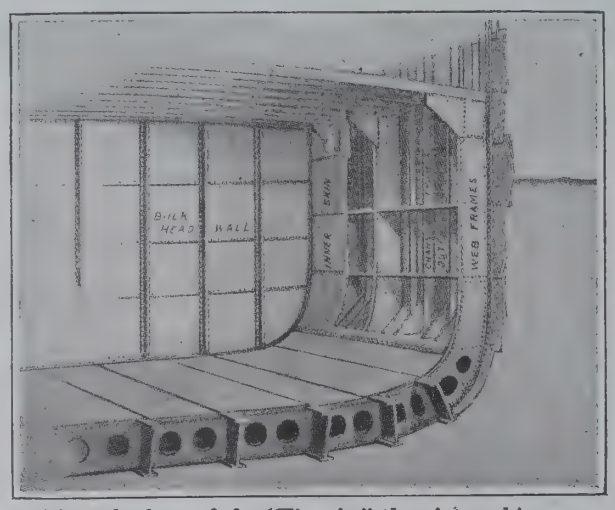
It was the delight of the skippers of those days, when they sighted a steamship ahead, to close in to within hailing distance, and sweep by the wallowing, smoking sidewheeler, while her steerage passengers jeered in derision at the "tin kettle." Twenty-five years passed before a steamship, the "Arizona," equalled the speed 18 knots achieved by the "Lightning."

### The Safest Ship Ever Built

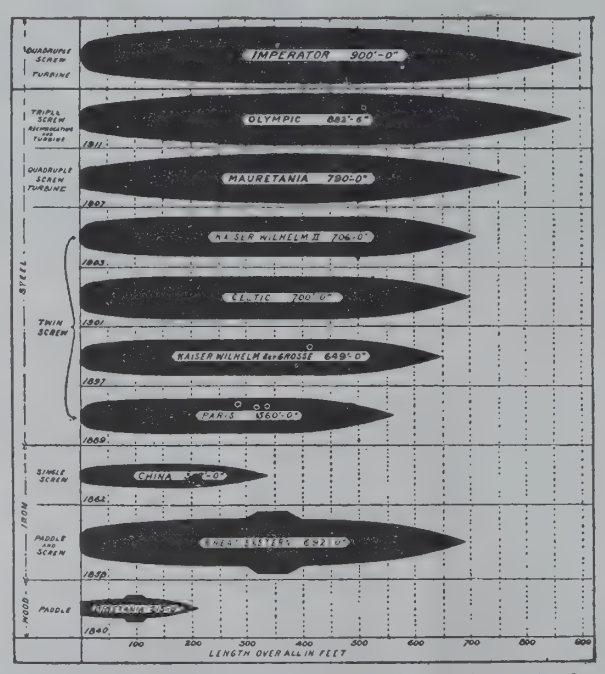
No review of the development of the steamship would be complete without mention of the "Great Eastern"—unquestionably the most remarkable ship ever constructed. In size, strength of construction and safety against foundering, and also in accommodations for the passengers, she was many decades ahead of her time. It was nearly half a century before her length of 680 feet was exceeded by the "Oceanic," of 705 feet. She was built by a company which was formed in England in 1853 to build a steamship which could carry enough coal to make the round trip to Australia and back at a speed of eighteen knots. That great engineer, Brunel, was entrusted with the design. Like "Britannia," his first iron, screw-propelled ship, the "Great Eastern," showed the inventive genius of her designer. Great attention was paid to the safety provisions. She was built with a double hull which extended ten feet above the water line and was closed in by an iron, water-tight deck. She had nine water-tight bulkheads, which were carried up to the top deck, thirty feet above the water line, and this top deck was built of iron and was double, with a space of two feet between the two decks. Longitudinal bulkheads were carried through the machinery and boiler spaces, and it is pretty safe to say that the "Great Eastern" would have survived the iceberg collision which sank the "Titanic." She was driven both by paddle wheels and propeller, a set of oscillating engines operating the former and an independent set of horizontal engines driving the propeller. She made her maiden trip from Southampton to New York in 1860, when her highest speed wos 14½ knots. The failure of the "Great Eastern" was due to the fact that sufficient passengers and freight could not be secured to make her profitable. Her best work was done in laying cables, the first Atlantic cable having been laid by this ship in 1866. In 1888 she was sold for old iron and broken up at Liverpool. The "Great Eastern" remains today the finest example of a safe ship. Gradually, in response to the demands of the steamship companies for economy of construction, the various safety devices embodied in her have been eliminated. Of the double hull, only the double bottom survives. The water-tight bulkhead deck has disappeared, and it has been lowered from thirty feet above water level in the "Great Eastern" to ten or twelve feet in most modern ships. Only in the Navy has the safety construction of the "Great Eastern" been preserved and amplified. The protection due to subdivision was proved by the ability of warships to endure terrific punishment by gun and torpedo.



**This shows the excellent sub-division of the former German steamship, "Kronprinzessin Cecilie" (now "Mount Vernon") which saved the ship when she was torpedoed during the war**



**After the loss of the "Titanic," the sister ship was improved by carrying the floor plating up the inside of the web framing so as to provide a double skin—a suggestion first made in the book, "An Unsinkable Titanic"**



**Growth of the transatlantic steamer from 1840 to 1912. Note how far the "Great Eastern" was ahead of her time. She was not exceeded until the advent of the "Oceanic" in 1899**

**The 25-knot "Lusitania." Length, 790 feet; beam, 88 feet; maximum speed, about 26 knots. This was the first of the fast, turbine, ocean liners**

The screw propeller was now rapidly driving out the paddle wheel, the "Scotia," of 3,807 tons being the last of the paddle-wheel ships built for the Cunard Line. She was the first to make the transatlantic passage in less than nine days. To the old Inman, later the American Line, is due the credit of bringing the passage below eight days with the screw steamer, "City of Brussels," of 3,747 tons. A memorable year was 1871, which saw the birth of the famous White Star Line, whose "Oceanic" and "Adriatic" introduced many features designed to increase the comfort of travel. The first ship to bring the passage below seven days was the "Alaska" of the Guion Line, and in 1889 the "City of Paris" reduced the time to less than six days. The last of the large liners to be driven by a single screw was that fine pair of ships of the Cunard Company, the "Umbria," and the "Etruria," which made their appearance in 1884. They were 525 feet in length and of 12,190 tons' displacement. Their single screw engines, the largest of their kind ever put into a steamship, indicated 14,500 horse-power, and the "Etruria" maintained a speed of 19.6 knots for the whole trip across the Atlantic.

To the Inman and International Company stands the credit for producing in the "City of New York" and "City of Paris" the first twin-screw liners, driven by triple expansion engines. These fine ships of 10,500 tons and 20,000 horse-power were a great advance upon anything built or planned in 1889, and it is notable that, together with the "St. Paul" and the "St. Louis," built by Cramp, of Philadelphia, which entered active service in 1895, these ships are still doing good work on the Atlantic route.

### Contest for Blue Ribbon of the Atlantic

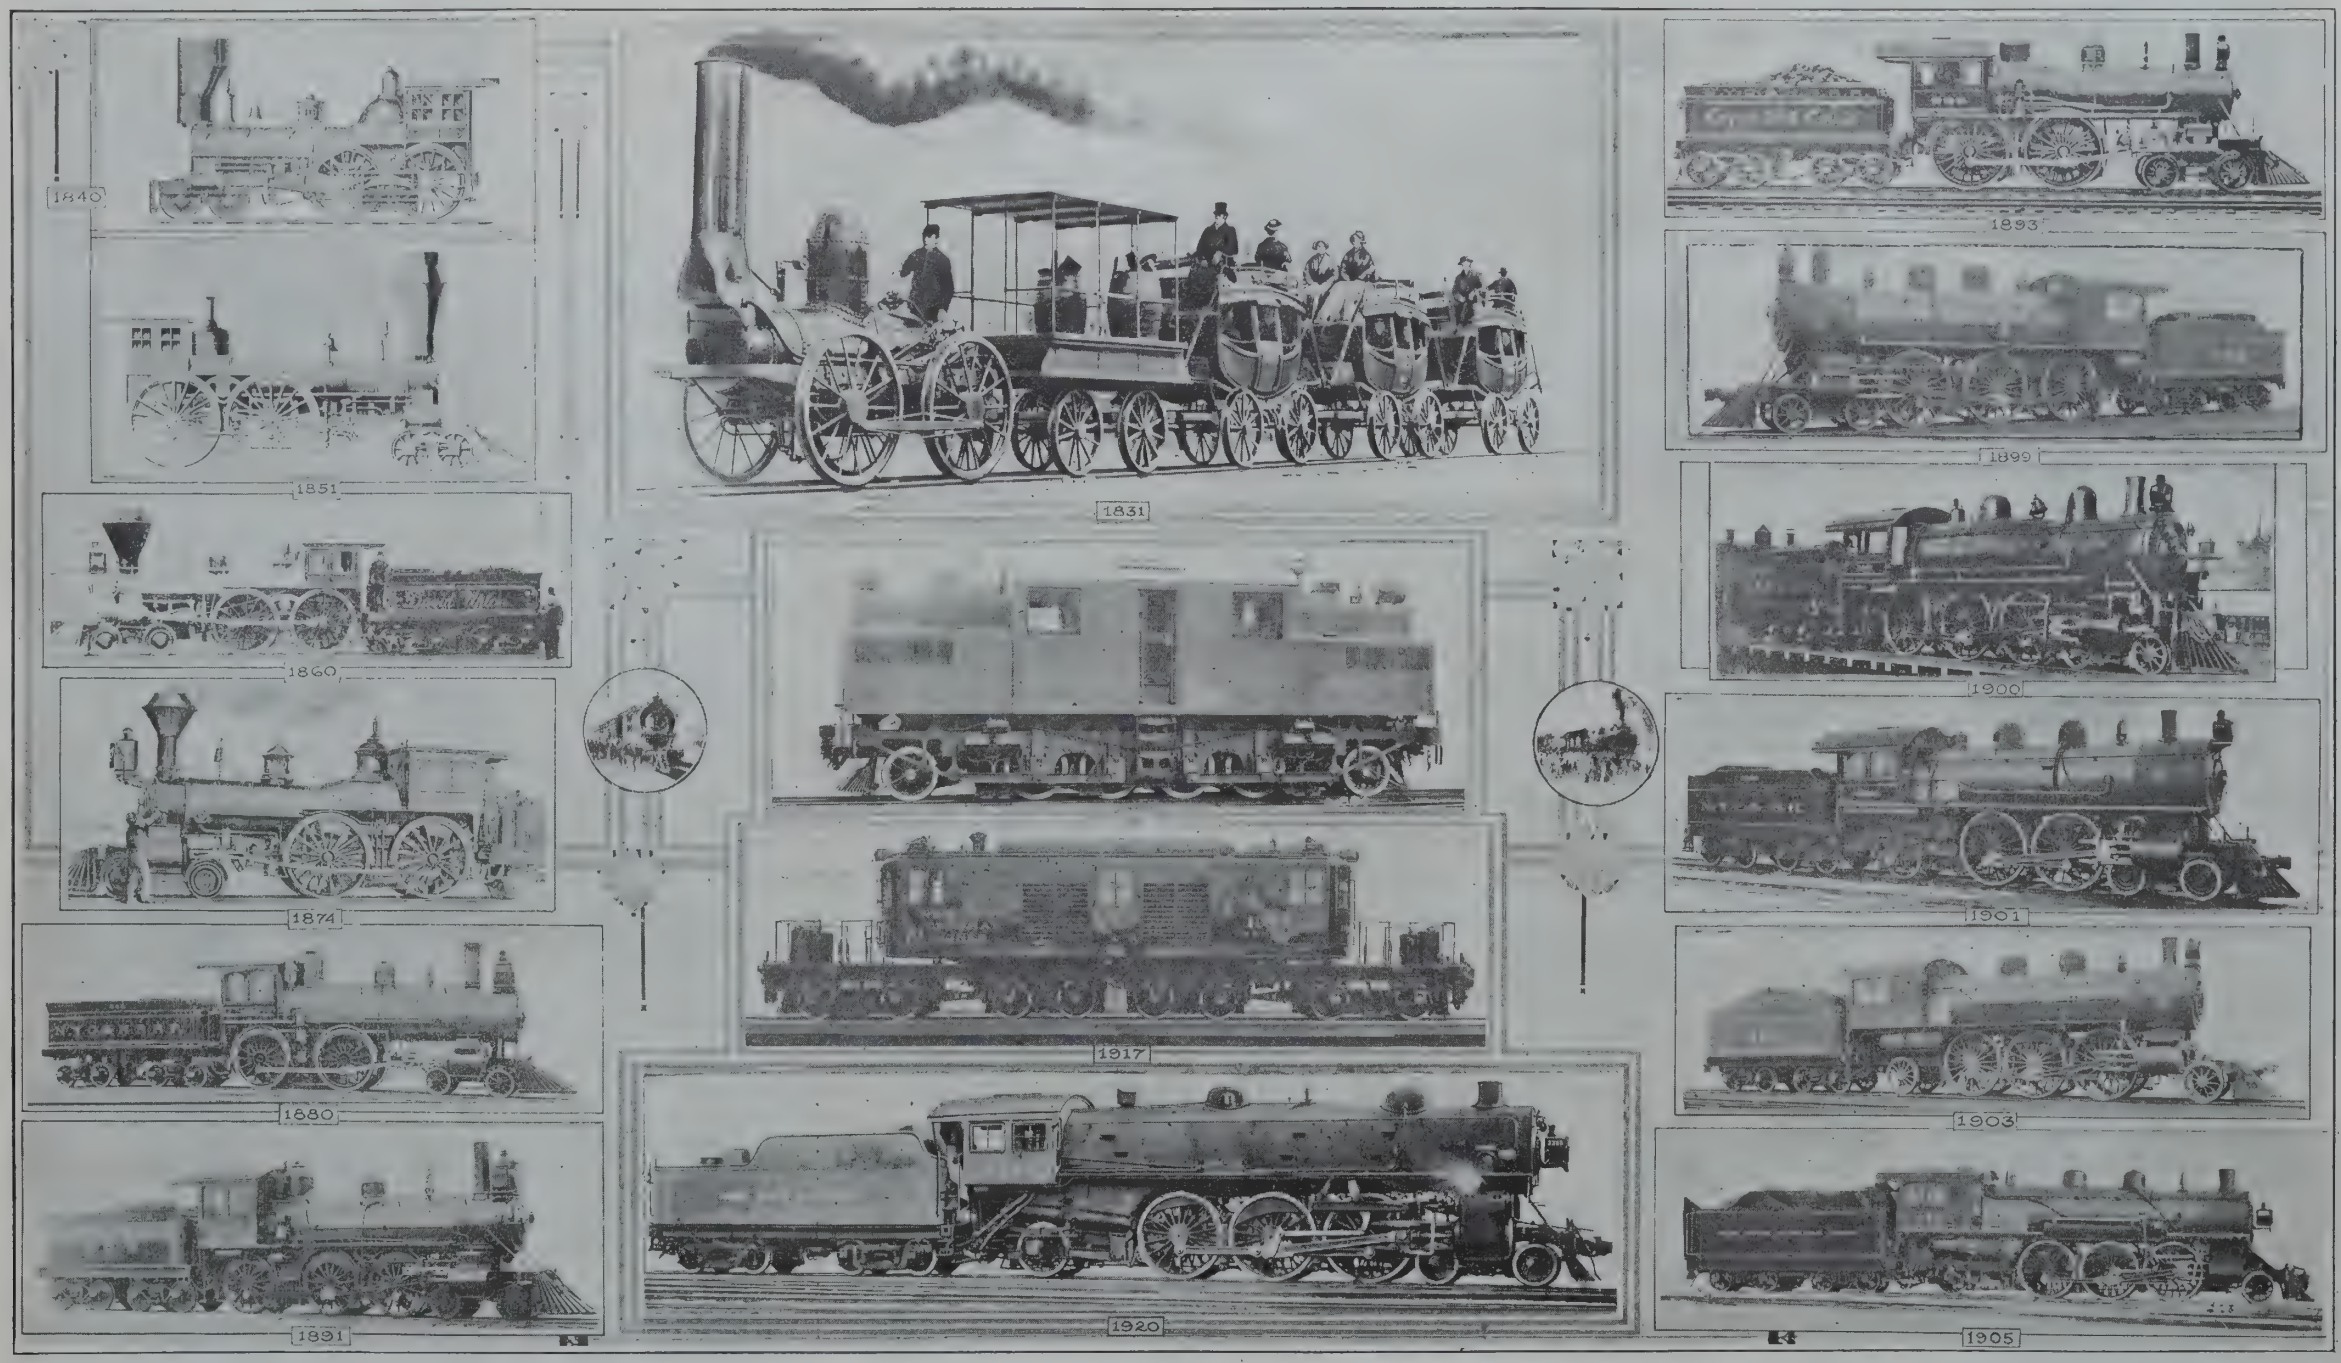
It is impossible within the limits of this article to follow in any detail the subsequent development of the transatlantic liner. The Cunard Company took the lead again in 1893 with the "Lucania" and "Campania," the first ships to exceed 600 feet in length. With 30,000 horse-power the "Lucania" crossed the Atlantic at a speed of over 22 knots.

Then, in 1897, the Germans, with the "Kaiser Wilhelm der Grosse" won the laurels. This was the first of the four-funnelled steamships of which the German companies, and later the British, were to build so many. In 1899, the White Star Company brought out the "Oceanic," 705 feet in length, the first modern ship to exceed the "Great Eastern" in length.

The Hamburg-American Line then made a bold bid for the blue ribbon of the seas with the "Deutschland," which, with 37,500 horse-power, maintained an average of 23.5 knots, thereby winning the record from the North German Lloyd, which replied by building the 707-foot "Kaiser Wilhelm II," which, with about the same speed, captured the transatlantic record.

The Germans had held the blue ribbon of the Atlantic for a whole decade when, in 1906, the Cunard Company built the "Lusitania" and the "Mauretania," 790 feet in length and of 44,500 tons deep-draft displacement. They were driven by turbines of 70,000 horse-power, operating four propellers, and they recovered the speed record from the Germans, the "Mauretania," crossing at an average speed of 26.06 knots per hour. This record was to stand for some twelve years, and in fact, still stands today, although it will probably be bettered by the "Aquitania," which has shown a great increase of speed since she was equipped with oil burners. On a recent trip to the eastward, she covered the last 129 miles to Cherbourg at the average speed of 27.40 knots; hence, it is probable that when she is shaken down, she will surpass the record made by the "Mauretania." Following the "Lusitania" and the "Mauretania," in the extraordinary growth in size of ocean liners, came the "Olympic" and "Titanic," 883 feet in length and displacing 52,000 tons. These vessels were furnished with magnificent accommodations, including gymnasiums, a swimming pool, sun parlors and all the conveniences of a modern hotel. Their speed was about 23 knots. Then followed the "Imperator," of the Hamburg-American Line with her length of something

# MILESTONES IN THE DEVELOPMENT OF THE AMERICAN PASSENGER LOCOMOTIVE



THERE were other locomotives before the "DeWitt Clinton," to be sure; but for our purposes it is well to begin with that historical train in giving a pictorial resumé of the development of the American locomotive. The "DeWitt Clinton" locomotive, built in 1831, was the second locomotive to be turned out by the West Point Foundry, and was put to work on the Mohawk and Hudson Railroad. By 1840 the American type locomotive, with four driving wheels and a four-wheeled swiveling truck, had made its appearance. The next illustration shows a locomotive of 1851 with a "cow catcher" or pilot. In the locomotive of 1860, the sandbox makes its appearance. It is interesting to note that locomotives of the Civil War period were highly ornamented, and were given names of railroad men, generals, presidents, and so on. This practice is still evident in the locomotive of 1874, which differs mainly in the matter of larger proportions for attaining still higher speeds. By 1880 the locomotive began to assume something like modern lines; indeed, locomotives of the type here shown are still in use on many of our smaller railroads and branch lines. The freight locomotive of 1891 has three sets of driving wheels, in order to insure better tractive effort for hauling the heavier trains then coming into use. In our locomotive of 1893 we have the famous "999," which broke the speed records of her day while drawing the Empire State Express. By 1899 we enter the era of large passenger locomotives, with three sets of drivers, and 1900 shows a further step in this direction. The locomotive of 1901 shows the debut of the well-known Atlantic type, with four coupled drivers, and a trailing truck under the cab. A six-coupled type of passenger locomotive is shown as the locomotive of 1903, as well as in 1905, each of these having a leading pony truck, and a trailing pony truck. On September 30th, 1906, the first electric train, drawn by the locomotive in the center of this group, left the Grand Central Station in New York City. By 1917 a still larger type of electric locomotive was introduced for hauling trains in and out of the New York terminal and for thirty miles out of the metropolis. The 1920 locomotive represents a modern Pacific type, with a leading truck, six coupled drivers, and a pair of trailers.

over 900 feet and a displacement of 54,000 tons. With 65,000 shaft horsepower she has made about 22½ to 23 knots. The next year, the fatal year of 1914, saw two other notable additions to the great Atlantic fleet in the "Vaterland," now the "Leviathan," 950 feet in length, and the "Aquitania," of 901 feet. The "Leviathan," when in good condition, can make 23 knots, and if she should be fitted as an oil burner, should make 24 knots or more. The "Aquitania" has been converted from coal to oil, with resulting additions as we have seen, to her previous speed.

### Coming of the Big Freighter

Side by side with the development of passenger travel on the high seas, there has been an even greater development of freight traffic. For many decades the passenger ships did double duty, all of them carrying more or less freight; but gradually there was evolved a special type of ship of great cargo-carrying capacity, deep and broad and of moderate engine power. In size these ships have shown a development comparable to that of the fast ocean liners, the capacity going up to 5,000, 10,000 and 20,000 tons and over, in the most modern examples. A combination of the large freight and passenger vessel is seen in the so-called "Express" ships, which by keeping down the speed to 15 to 17 knots are able to carry a large tonnage in the hold and provide comfortable and extensive passenger accommodations on one or more superstructure decks amidships.

The latest development and one that is destined to have a profound effect upon ocean transportation is the use of oil, either as fuel in place of oil in steam-driven ships, or directly in the cylinders of internal combustion motors. The latest application to the "Olympia" and the "Aquitania" has raised the speed and greatly reduced the cost of operation of these famous ships. The only limitation upon the use of the internal combustion motor is the size of the individual cylinder that can be used to advantage.

**These two photographs show what electrification has made possible at the Grand Central terminal. The tracks were lowered and roofed in, the streets restored, and fine office buildings and hotels have taken the place of the unsightly terminal tracks and yard**

## Seventy-five Years' Growth of the Steam Railroad

BECAUSE of our comparative isolation from the rest of the world, particularly during the early years of the development of our railroad system, the American railroad has marked characteristics which distinguish it as regards its track, rolling stock and general equipment, from the railroad systems of the rest of the world. These differences were due to several causes, chief among which were the comparative scarcity of our population, the great distance to be covered in those early years, the scarcity of capital and the demand for cheap and rapid construction. In Europe, with its denser population, the completion of a new railroad found passengers awaiting it on every platform and freight in every freight shed. In Europe the railroads followed the population; but in America they preceded it. Our early constructions were essentially pioneer railroads. They were built rapidly and cheaply, and were thrust out sometimes a thousand miles or more in advance of the oncoming tide of pioneer settlers. It was impossible, if the work was to be done within a reasonable time, to build our early railroads in the substantial and costly way that characterized the European work. We had to cut according to our cloth, if we may use that figure of speech, and leave the work of reconstruction to a later day when the increase of population, industry and commerce should make possible the inevitable rebuilding.

### Low Cost of the Early Railroad

In accordance with this policy, in locating a new railroad, the engineer avoided heavy cuttings and costly tunnel work; which meant that these early lines must be full of curvature and contain many heavy grades. Fortunately, the problem of bridging was simplified by the extent and number of our great forests. The Howe Truss timber bridge and the many-storied trestle carried our railroads cheaply and expeditiously across many a great river and the deep chasms and ravines of broken, mountainous country. In the days when the SCIENTIFIC AMERICAN made its first appearance, railroad track in America consisted of forty to fifty-pound rails laid on small ties, which more often than not were laid upon the graded ground without the use of any ballast. The introduction of Bessemer steel brought a stiffer, more durable and harder rail, and steel began to take the place of wood in bridge construction. As traffic grew and funds became available, the early lines were relocated and heavy mountain grades were eliminated by piercing the summit with tunnels. Heavy grades and sharp curvatures were reduced, extensive ballasting was undertaken and gradually American railroad track, at least on our leading roads, was brought up to the level of the best European practice. From the 40-pound railroad of 1845, we have gone up to the 125-pound rail of 1920; and from a single track laid upon the graded ground, our trunk lines have gone up to four-track roads bedded upon from eighteen to twenty-four inches of broken stone ballast.

How many readers of the SCIENTIFIC AMERICAN are aware that practically the whole of our railroad system, totalling some 260,000 miles, has been built during the life of this journal? For it is a fact that in 1845 there was in the whole United States only 4,633 miles of railroad, consisting of a few disconnected lines in the Atlantic and Southern States and in the Middle West. In that year the Eastern railroads were just beginning to creep across the Alleghenies into the Mississippi Valley. Taking the growth of the system by decades we find that from 1845 to 1855, our railroads grew from 4,633 miles to 18,374 miles. By 1865 the total was 35,085 miles, and ten years later, 74,096 miles. In 1885 it had risen to 128,320 miles, and by 1895 to 180,657 miles. At the opening of the present century, the 200,000-mile mark had been passed, and today the system has grown to about 260,000 miles.

### Opening of First Transcontinental Road

A red-letter day in the course of this progress was May 10th, 1869, when the first transcontinental road, the Union Pacific, was completed. The American passenger car, a distinctive type, with its long body mounted on swivelling trucks, was patented in 1834; and ten years later, when the SCIENTIFIC AMERICAN made its first appearance, it had come to be the typical American car. In those days it was a small and crude affair—forty to fifty feet long, lighted by oil lamps and warmed in the winter by wood-burning stoves. The improvements have been in the direction of comfort and safety. The oil lamp gave place to Pintsch gas, and steam taken from the engine replaced the dangerous wood or coal stove. The final development was the elimination of wood in favor of steel car construction, a change which has greatly reduced injuries and death due to collision and derailment. Another notable year was 1864, when Pullman brought out his first sleeper and thus led the way in a system of night travel which has become universal. Among all the inventions that have promoted speed and safety on the railroads, first place must be given to the automatic airbrake and block signal system. The airbrake, named after its designer, George Westinghouse, Junior, was first put into service in 1868-69. By this system, the engineer can set the brakes on every car and on his own engine by the manipulation of a small lever, and should the train break apart, the brakes will automatically set themselves. The automatic brake has been continuously improved, as will be seen by the following comparison. In 1890, a 280-ton train running at 60 miles an hour could not be stopped in less than 1,000 feet; but in 1915, a train weighing 950 tons and moving at 60 miles an hour, if equipped with the brake system of 1890, could be stopped in about 1,760 feet; while with the present improved electro-pneumatic Westinghouse airbrake it can be stopped in 860 feet.

### Block Signal and Automatic Stop

The greatest safeguard against railroad collision, the block signal, was developed mainly in Great Britain, where as far back as 1890, over 98 per cent of the

# Seventy-Five Years of Applied Electricity

## From the Telegraph of 1845 to the Radio Station of Today with a Range of Twelve Thousand Miles or More

ELECTRICITY has long been known to the scientist and experimenter, but its practical application is only of relatively recent date. Indeed, one year before the SCIENTIFIC AMERICAN was founded Morse opened his experimental telegraph line between Washington and Baltimore. That was in 1844. And telegraphy, at that time, represented the only practical application of that great and mysterious force which we call electricity.

Yet one thing is certain about applied electricity, and that is its rapid development. Following the advent of the Morse telegraph, inventors in many parts of the world set to work putting electricity to all kinds of use. In fact, the whole story of applied electricity is one of almost countless inventors in many different countries striving for the same ends; of simultaneous and identical inventions by widely separated inventors; and of developments whose origin it is difficult to trace because of the multiplicity of separate contributions entering into them. And so this story must perforce devote itself to the better known men who have done much to make electricity what it is today, without mention of many other contributors to the art whose names and achievements cannot be stated in detail for want of space.

### From Plunge Battery to Dynamo

The past seventy-five years have witnessed the development of applied electricity from the plunge battery of the laboratory bench and schoolroom demonstration to the huge turbo-generator units of today, which furnish power for driving our electric railroads, turning the wheels of our factories, lighting our homes and business places, furnishing heat for cooking a meal or for producing carborundum in the electric furnace, and so on. In fact, applied electricity would still be in its infancy were it not for the almost unbelievable strides made in the generation, control and distribution of electric energy.

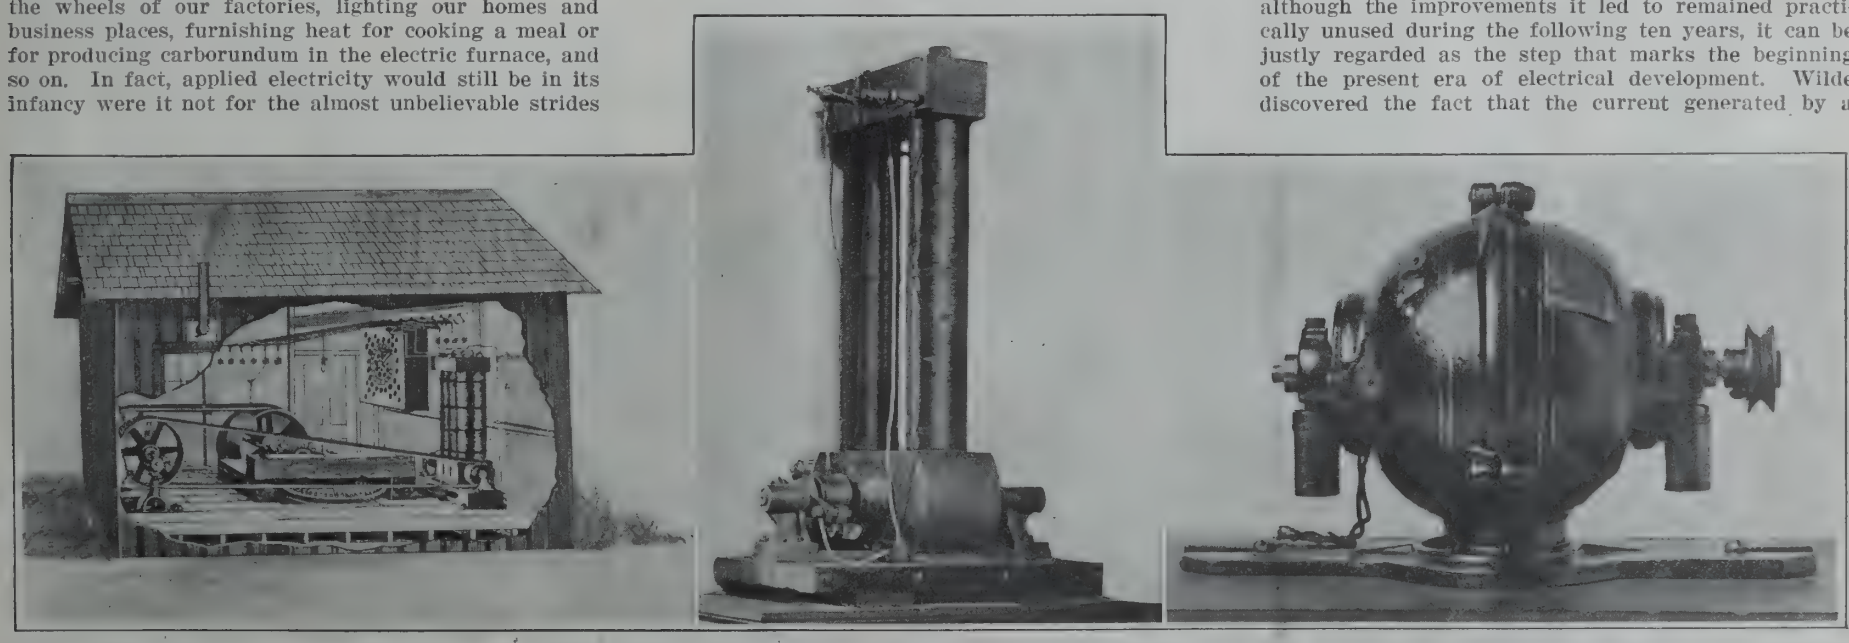
From 1850 to 1875 great advancement took place in the way of development of electric theories, and the demonstration of the laws that govern electro-magnetic actions. Since 1875 the progress has been more in the expansion of theoretical knowledge, and this is just contrary to the general impression in relation to the subject. Anyone who has doubts as to the correctness of this statement, however, can have them dispelled by a careful study of the electrical literature of the period. In the early seventies, for instance, Prof. James Clerk Maxwell brought out a masterly treatise on electricity and magnetism, in which practically every known law or principle relating to electricity and magnetism was covered.

The numerous effects of electro-magnetic action were extensively investigated at an early date, but their true relation to each other and to the other forces of nature were not properly understood until the doctrine of the conservation of energy was established upon a firm basis. Owing to this fact some of the most distinguished men of seventy-five years ago advanced views that were decidedly at variance with the facts and only served to assist charlatans in their efforts to defraud investors. So it followed that the development of the art was retarded materially until something of a very definite and authentic nature could be learned about electricity. It was this theoretical study that paved the way for the development which followed.

Soon men in various countries got to work on the problem of generating current in larger volume and at less expense than was possible with the usual battery which consumes zinc at an alarming rate for its small output. The electric motor in crude form already existed, and it was known that the motor, if made with permanent steel magnets for the field, would act as a generator of electricity if driven at a sufficiently high speed. Faraday, as far back as 1831, had demonstrated this method of developing current.

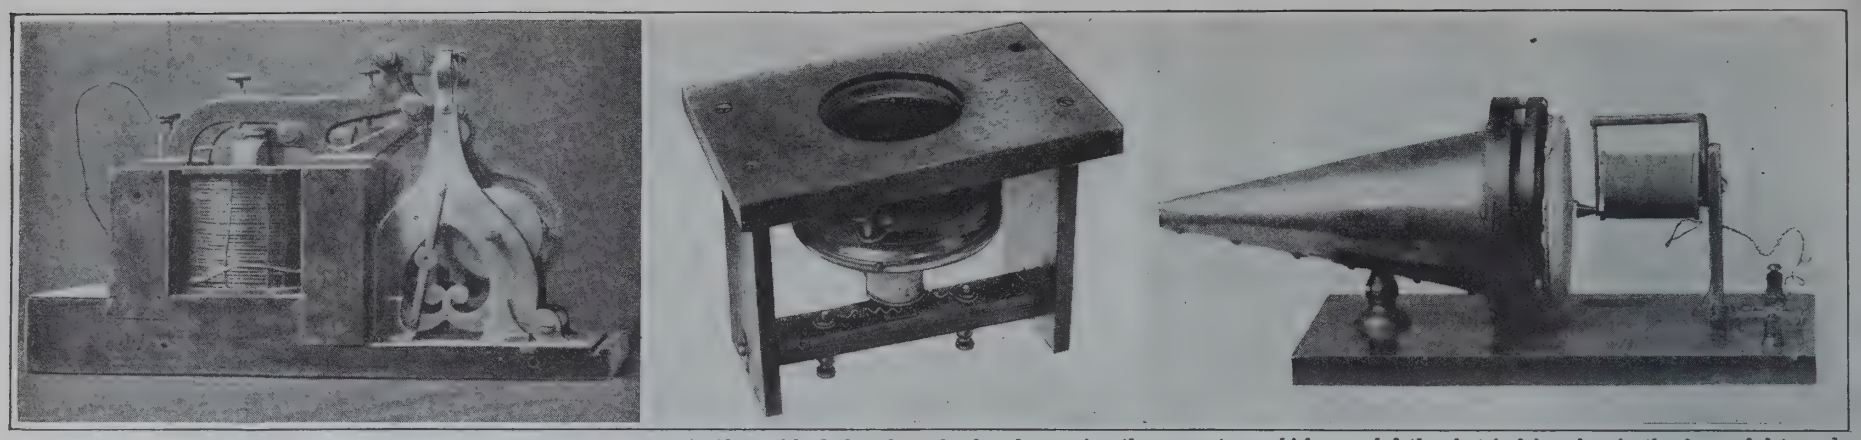
Although J. S. Woolrich constructed a generator of considerable size for the days of 1841, it was not until 1861 that anything of note was accomplished in the field of electric generation. In that year Holmes brought out a large machine of sufficient capacity to be used for arc lighting, or, more properly speaking, for furnishing current to one arc light. This machine generated current at much lower cost than the electric batteries, but its size was very great in comparison with the work it would do, and its construction was of such character as to be necessarily very expensive. Several other large machines of this type were designed and constructed during the next few years, but owing to their cost and bulkiness they did not meet with favor. The first direct current motor was built in 1860 by the Italian physicist, Antonio Pacinotti. His machine consisted broadly of an iron ring, suitably wound, which rotated between the poles of a horseshoe electro-magnet supplied with current from a battery. In the same year Pacinotti invented the commutator, which was reinvented by Gramme some years later at a time when the dynamo was waiting for just such an improvement.

In 1866 Wilde developed a machine which was the stepping-stone to the generator of the present day, and although the improvements it led to remained practically unused during the following ten years, it can be justly regarded as the step that marks the beginning of the present era of electrical development. Wilde discovered the fact that the current generated by a



*Left:* Earliest central station in United States, built for illumination purposes.. *Center:* One of Edison's early bi-polar dynamos. This type of machine gave remarkable results for the requirements of pioneer electrical days, and motors of this same type have remained in use even to this day in isolated instances. *Right:* This motor has the distinction of being the first motor to be operated by current generated at Niagara Falls and transmitted some distance over lines

**Three phases in the generation and application of electric current**



*Left:* The original Morse receiver used on the Washington-Baltimore line in 1844, with clockwork mechanism for moving the paper type which recorded the electrical impulses in the form of dots and dashes. *Center:* Bell's original Centennial iron box receiver. During the exercises inaugurating the trans-continental telephone service between New York and San Francisco, Dr. Bell used a replica of this instrument with good results. *Right:* Bell's adjustable telephone of 1876. This was a receiver, and the ear was placed at the small end of the sound horn

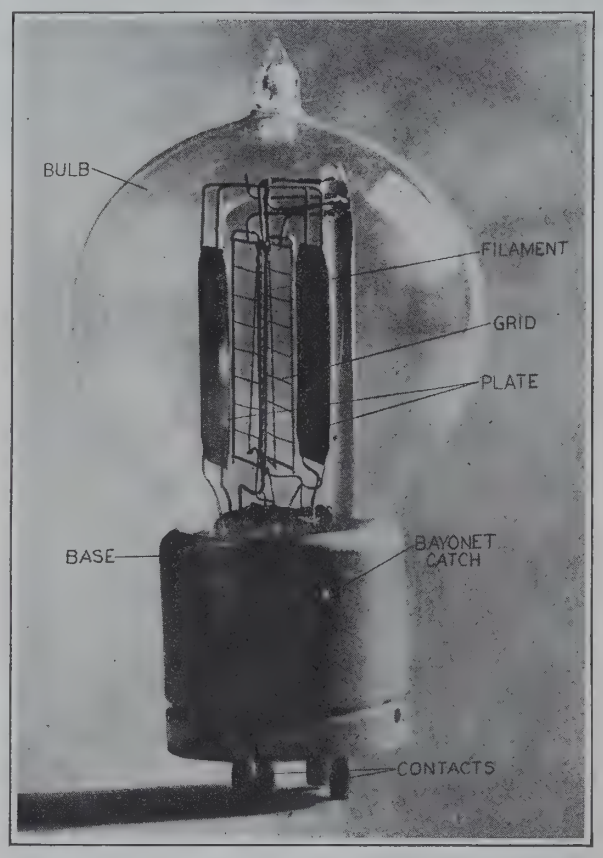
**Pioneer days of telephony and telegraphy as reflected by typical apparatus**

small magneto machine, if used to energize a powerful electro-magnet forming the field of a larger machine, would enable the latter to develop a current many times greater than that of the small machine. This discovery resulted in directing the attention of scientific men to the subject with renewed vigor. After a careful consideration of Wilde's work, the conclusion was arrived at that if a comparatively small machine could energize the field of a much larger one that would generate a current many times greater, it ought to be possible to use a part of the current of the large machine to energize its own field, and thus dispense with the smaller machine. But it was thought that the assistance of the small machine would be required to start the action. By actual trial it was found that the larger machine would start a current without assistance of the small one. And that was the basis of the present generator.

### Refinement Follows Refinement

From 1866 to 1876 very little was accomplished in the way of practical development, but quite considerable in the way of improving the dynamo or generator. In the machine of Wilde and several others that immediately followed it an armature was used that gave pulsatory current. Gramme made an improvement in this direction by adopting a ring-shaped armature upon which the wire was wound in a great many sections, the ends of which were attached to a commutator of a corresponding number of sections. The result of this construction, known as the commutator, was to produce uniform current, and the former destructive sparking of the brushes was practically eliminated. Siemens, also, worked in this line and accomplished the same results by the use of a drum-shaped armature.

From 1876 on the development of the electric generator was accelerated. Edison turned his inventive genius to the problem of the generator and current distribution at about that time. Both Edison and Weston hit on the idea of the three-wire system of current distribution, thus making electricity available over a wide area at a low cost. In 1878 Charles F. Brush introduced his famous compound dynamos, at a time when Edward Weston's dynamos were also in the market. In 1880 Gaulard and Gibbs worked out a system of distributing alternating current at high tension. They utilized induction coils, which were transformers, but which they called "secondary generators." This early transformer was one of the first steps which rendered it possible to transmit electric energy to great distances. Déri and Zipernowsky, in 1882, improved upon this work, and the term "transformer" came into being.



The action of the vacuum tube is still a matter of conjecture. Generally, its action is said to be due to the emission of a constant stream of electrons from the heated filament to the plate or plates, regulated by current on the grids

**Typical vacuum tube and its essential members**

But the modern transformer system, which involves transmission from a station of high potential and the reduction of the potential in the secondaries of transformers, was worked out in a small way at the Franklin Institute in Philadelphia in 1879, by Prof. Elihu Thomson. In fact, all the way through the development of electric generation, distribution, and application we come across the extensive and invaluable work of Prof. Thomson.

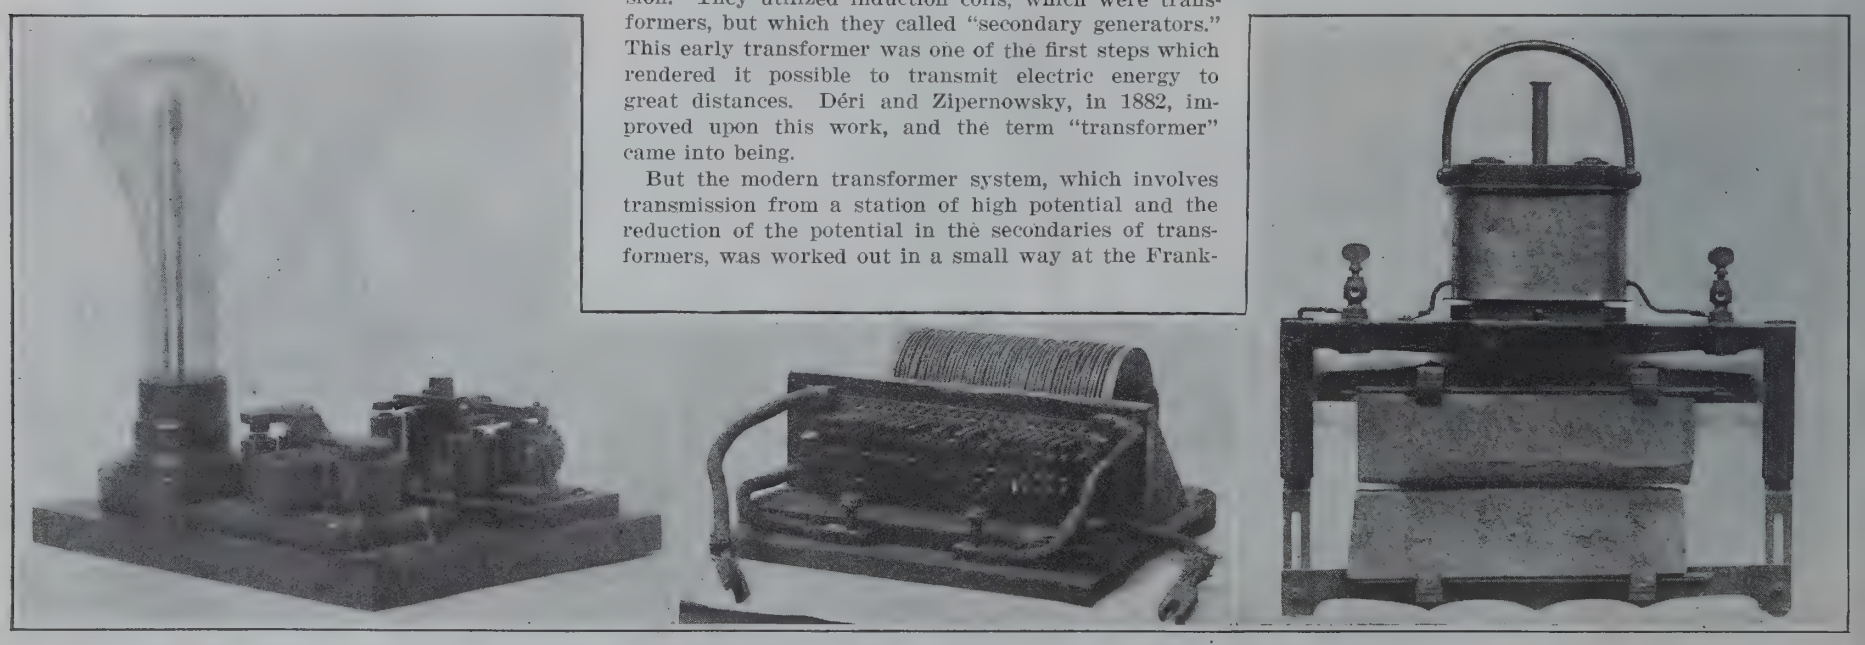
The storage battery, which plays an important rôle in power generation, began to assume practical form in 1882 when Camille Faure improved Planté's accumulator by inventing the pasted type of storage battery. Planté formed his super-oxide of lead after charging; Faure used a compound of lead oxide and lead superoxide, which he applied directly to the negative electrode.

The first alternating current central station of London was built by S. Z. de Ferranti somewhat later, and it served as a model for subsequent installations. In 1887 Nikola Tesla invented the polyphase alternating current motor which made it possible to transmit electrical energy still more economically. The first alternating current machine for generating polyphase current seems to have been built in 1888 by Hasselwander. In the same year Chas. S. Bradley patented a two-phase motor. The first installation for transmitting multi-phase alternating current at high tension was built in 1891 by von Dolivo-Dobrowolski of Berlin, between Lauffen and Frankfurt.

Refinement after refinement followed from that day to this. The introduction of the steam turbine caused the building of still larger generators than were used with the greatest of reciprocating engines. The demand for cheap electric power caused the harnessing of mountain streams and the transmission of the power many hundred miles to the consumers in the distant cities. The nickel-iron storage battery came into use, being invented by the Swedish engineer, Jungner, but perfected and placed on the market by Edison.

### The Rise of the Electric Motor

Peculiarly enough, the motor antedates the generator. Indeed, any of the electro-magnetic motors in which the current was reversed would have generated a current so strong, if they had been rotated backward, that its presence could not have escaped notice. Yet hundreds of these machines were experimented with for

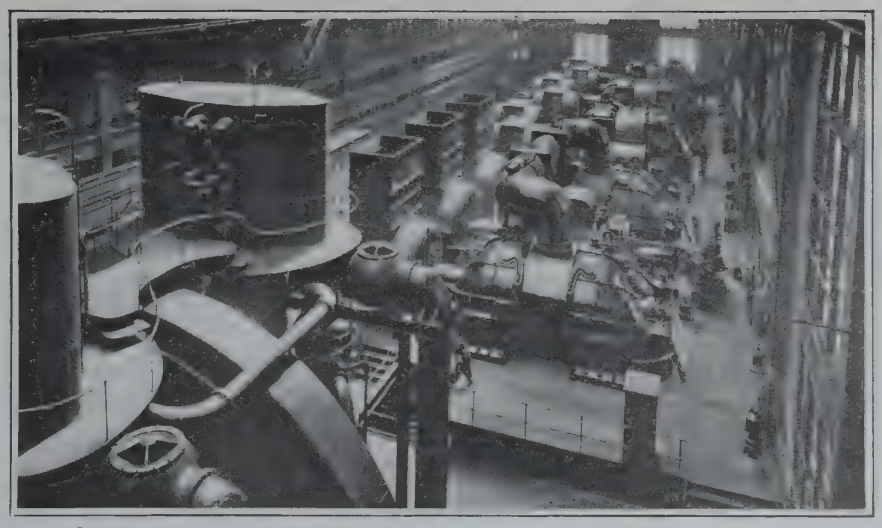


*Left:* Carbon arc type of electric lamp patented by Hiram Maxim on September 24th, 1878. *Center:* Original electric welding transformer invented by Elihu Thomson and extensively used as early as 1886. *Right:* Arc lamp invented by Wm. Wallace of Ansonia, Conn. The peculiar feature of this lamp was the use of the carbon plates 10 inches wide, between which played the arc

**Milestones in the development of the electric lamp and the process of electric welding**

more than a quarter of a century and the fact was never discovered, although all the while there was urgent need for some cheaper form of current generator than the usual zinc-consuming battery.

The development of the electric motor has followed more or less closely that of the generator; to be sure, for all practical purposes the motor and the dynamo are almost identical in general design. With the improvement in the generation of current, the motor, too, was improved, and its mechanical capacity kept pace with the electrical output of the generator. It remained for the pioneers to develop suitable systems for the economical distribution of current before the motor became a universal source of power, such as it is today. Year after year we find the electric motor growing in importance until it seems that practically every piece of machinery in the shop, store, home and elsewhere is driven by electricity, providing there is a source of current within ready reach.



**A modern power-house showing the former reciprocating engine in the foreground and the latest type of turbine units farther back**

The most startling application of the electric motor was no doubt the electric railway, beginning with the experimental attempts of Davenport in 1837. The possibilities of the electric motor in this field were seriously considered long before the electric motor made headway in other directions. In 1851 the versatile and daring Moses G. Farmer of Newport made rather unsuccessful experiments with an electric railroad, in which the current, derived from a battery, was sent through the rails. In 1851 Thomas Hall of Boston succeeded in driving a vehicle with a magnetic machine supplied from a stationary battery—an early attempt at electric automobiling. In 1854 M. Davidson also made experiments with an electric automobile. Numerous inventors tried their hand at the electric railway, which seemed to be a most difficult problem to solve despite its apparent simplicity in the light of present-day knowledge and equipment.

In 1879 Siemens constructed an experimental electric railway which actually carried passengers. Several others worked in this field in the following years, including Edison, who constructed a full-sized electric railway at Menlo Park during 1880-82. However, it was not until 1888 that complete success on a commercial scale was attained. The equipment of all the street railways of Richmond in that year, and the complete success of the installation, was the real beginning of the introduction of electricity for the operation of railways. As in the case of the dynamo and the motor, one refinement has followed another in the development of the electric railway and the electrified railway. As recently as 1901 Frank J. Sprague, the well-known American electrical engineer, invented his famous multiple unit system of control for electric railways, which has made possible the operation of electric trains in our subways and on our elevated railroads. In 1902 B. G. Lamme of the Westinghouse organization brought out the high tension motor for single phase alternating current, which was soon introduced on electric railways. And with a few more additions this brings us to the present electric railways which make their way through our city streets and spread far out in the country so as to weave suburbs and hamlets and cities into one, and to the present electrified railways which have banished the snorting, smoking and noisy steam locomotive.

### How Electric Lighting Came About

Again we must mention that enterprising person, Moses G. Farmer of Newport, who in 1859 illuminated his house with forty-two platinum incandescent lamps, thus giving us one of the earliest instances of electric lighting. But it was many years before electric illumination was systematically developed.

The arc lamp and the incandescent lamp bore more points in common in the early days than they do now. For example, the first arc lamp to be extensively commercialized was the "candle" of Jablochkoff in 1876, which gave less light than many of the modern incandescents do, and embodied a "filament" at the top, the fusion of which started the arc. On the other hand, among the earliest incandescent lamps were the so-called "incandescence-arc" lamps, based on the principle of an arc playing between two incandescent wires in a partially evacuated bulb. Again, the material in both cases was the same, carbon being used for lamp filaments and arc electrodes. Subsequent development soon caused the two forms of electric illumination to drift further and further apart, as the arc lamp continued to use carbon and metallic electrodes and the incandescent lamp turned to osmium, tantalum and tungsten.

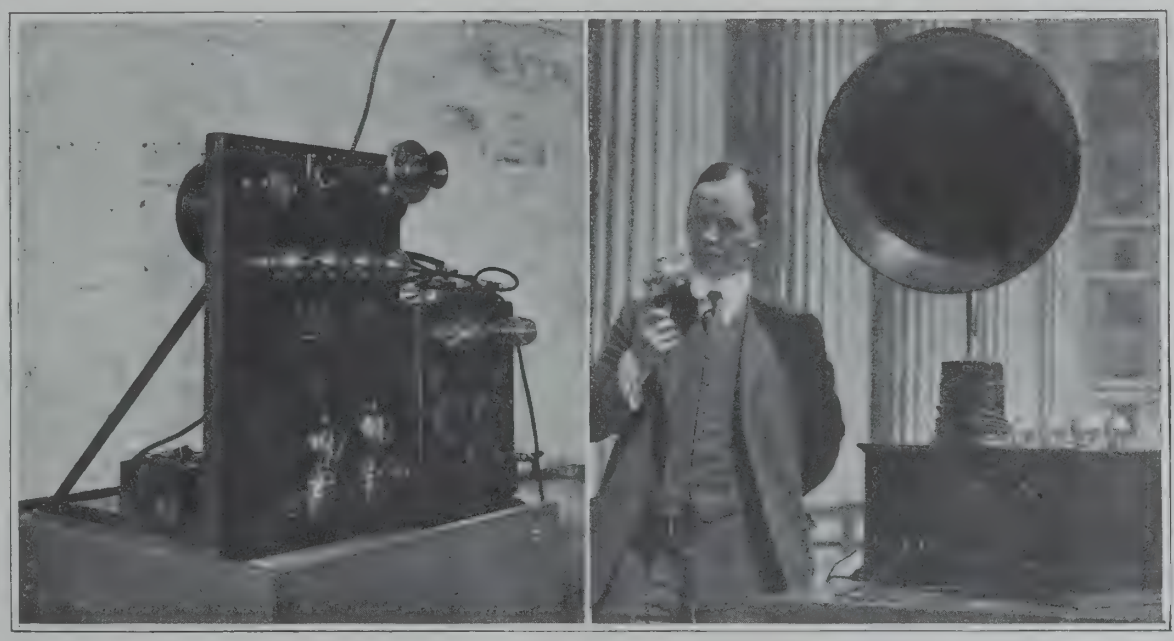
The arc lamp is a device of long standing in the art. Indeed, Sir Humphry Davy in 1801 first observed and studied the phenomenon of the electric arc. It was not publicly exhibited until 1809, when Davy, in the absence of a generator—he was too far ahead of electrical developments—made use of a mammoth battery of 2,000 primary cells at the Royal Institution, London, for his current.

We now skip several decades, during which the idea of electric illumination received much attention by experimenters and scientists, both in the form of crude attempts and in simple suggestions. Some of the suggestions and actual lamps are interesting and ingenious, but of little if any importance as far as the advancement of the illuminating art is concerned.

In 1875 the Sprengel vacuum pump, which became almost immediately an important factor in solving the problem of successful incandescent lamp manufacture, was introduced. The following year Lieut. Jablochkoff patented his famous "candle," consisting essentially of two vertical strips of carbon separated by a thin fusible insulating barrier, across the top of which an electric arc played. Europe proved quite a good market for this odd "candle," but it met with little success in the United States, where it came in direct competition with the early incandescent lamps.

Meanwhile Charles F. Brush and Thomas A. Edison applied themselves to the stupendous and hitherto unsolved problem of utilizing electricity for general illuminating purposes. Brush exhibited his first arc lamp of the wonderfully simple and successful ring-clutch type in 1877, and in the next year introduced that other indispensable feature of his system, the series arc dynamo, and started arc lighting campaigns all over the world.

The history of the arc seems incomplete without mentioning the early work of Elihu Thomson. He invented a generator, absolutely unique. In connection with it he developed the magnetic blowout, which has been extensively employed ever since in controllers, lightning arresters, and circuit breakers. Indeed, the Thomson-Houston and Brush arc systems were active competitors.



*Right:* One of the many uses to which the vacuum tube has been put is the loud-speaking telephone. This apparatus enables a speaker to address tens of thousands of persons without raising his voice. He speaks into a mouthpiece and a bank of vacuum tube amplifiers magnify his voice many thousands of times until it thunders out of the huge horn. *Left:* A typical wireless telephone transmitter which can be attached to any standard light socket and operated on either direct or alternating current. Vacuum tubes play the leading role in this, as well as in all small and medium sized radio telephone transmitters

### The Great Search for Filament Material

In 1879 several inventors were working on the incandescent lamp problem, among them Sawyer and Man, who experimented extensively with filaments of carbonized paper; Lane-Fox, who used vegetable fibers; Swan, who publicly exhibited a lamp with a filament of parchmentized thread; Weston, who worked even at that early date with squirted and cut nitrocellulose, and Edison, who tried out substances far too numerous to mention here, but including platinum, lamp-black, tar, and paper. There were numerous failures among those working on the incandescent lamp problem, but these did not deter other inventors and experimenters from going ahead with what seemed such a futile search for a suitable filament material.

# The Rise of the Automobile

## How One of the Props of Modern Existence Came Into Being and Acquired Its Present Position

*THE first successful four-cycle gas-engine was built in 1876. The first successful application of such an engine on a vehicle took place in 1887. The manufacture of horseless carriages for sale was first undertaken in America in 1894. The industry was first recognized in the census reports of 1899, with an output of 3,700 cars. The truck was first differentiated from the passenger car in 1904. The million mark in annual production was first passed in 1916. Today there are seven million in operation in the United States. The automobile has been developed from its inventive origin in less than fifty years. Its manufacture has been developed from nothing in less than twenty-five years. In this time it has come to be the most vital single adjunct of modern civilization. Truly we are living in a rapid era.*—THE EDITOR.

VEHICLES to propel themselves were designed long before the day of the internal-combustion engine. But the very name of road engine given to these as a class emphasizes their utter lack of true historical connection with the automobile of the present day; they represent merely isolated individual effort and are of antiquarian rather than historical interest. At the same time, we have automobiles on our roads today that run on other principles than that of the gas engine, and their proponents look more or less confidently toward their ultimate domination of the field.

But the purpose of this issue is to tell, not of all that has been or may be, but rather to show how the big things of today that did not exist 75 years ago have come into being. It seems therefore desirable to recognize that when we say "automobile" we mean the gas-driven car that dominates the field today; and, excluding the abandoned ideas of yesterday and the potentialities of tomorrow, to tell the straight story of how the machine was created that depends for its operation upon the explosion of a charge of gas within its vitals.

This story necessarily begins with the engine. The road locomotives of the decades before the 80's were so cumbersome and so generally objectionable as to make it clear in the retrospect that automotive progress waited on some new departure in the way of prime mover. With the ordinary cannon and rifle before him, the imaginative inventor of many generations realized that here was a means of power that wanted only proper control. As early as 1794 the British patent records give testimony of this realization; but the first essential of compressing the charge before firing was missing. William Barnett, in 1838, first grasped the necessity of compression; he was likewise the first to effect a moderately sensible solution of the ignition problem, designing a plug-cock that transferred a flame from outside the cylinder to inside at the critical moment, in spite of the apparently insuperable obstacle that the internal pressure was greater than the external.

The first man to attempt the explosion of the charge by means of the electric spark was E. Lenoir, in 1860; but while he manufactured several hundred engines, the ignition was not reliable. Neither did he have the proper conception of how to handle his explosive mixture. Clear ideas on this subject were first promulgated in 1862 by A. Beau de Rochas, who published a little pamphlet in which he defined clearly the intake, compression, power and exhaust strokes, and showed plainly why the cycle of these four operation was essential to the development of the internal combustion engine.

### Otto's Engine and What Came of It

The Frenchman's work was lost sight of, however, and his four-stroke cycle had to be invented independently by N. A. Otto, who embodied it on his engine of 1876. This is so distinctly the parent of the modern internal-combustion engine that Otto is recognized as the inventor of this device. But his engine was sufficiently crude, in comparison with those of today.

In the first place, it was of a single cylinder, necessitating a fly-wheel of disproportionate bulk to carry the piston over the three unproductive strokes. The explosive medium was a mixture of gas and air, effected as today, before introduction into the cylinder; it was fired by means of a metal tube heated to incandescence. This tube led into the cylinder, through a valve which opened at the proper moment. The gas flowed into the tube, ignited, and communicated the state of explosion to the main body in the cylinder. The ignition valve closed at the completion of the exhaust stroke; like intake and exhaust valves, it was operated mechanically, but by gears rather than the cams of today.

There remained much to do to the Otto engine before it could be put on an automotive vehicle. It was a heavy, slow-running affair, making from 150 to 250 revolutions per minute. The engineers of the day believed that any greater engine speed was incompatible with durability and smooth running. Gottlieb Daimler showed the error of this by producing, between 1883 and 1887, small light engines running at about 800 revolutions. Another fundamental innovation, which, while not original with Daimler was first a complete success with him, was the use of a liquid fuel. This, of course, necessitated something in the way of a carburetor to impregnate the air passing to the cylinders with the vapor from the fuel. Preceding efforts in this direction were based on a faulty principle, relying on the air to pick up enough vapor while passing over or bubbling through the liquid. Under such treatment, however, the heavier fractions do not get taken up; the liquid in the mixing chamber gets heavier and heavier, until finally it comprises nothing that the passing air can take into suspension.

Daimler invented a device which, while lacking proper response to changed speeds and loads, in its essential features anticipated the modern float-and-jet carburetor. In his light, fast engine with higher compression than before, and his easily handled liquid fuel, he had the main ideas necessary to the installation of a gasoline engine on a vehicle. He actually equipped bicycles and carriages with his engines; and on March 4th, 1887, he operated the first gasoline-propelled motor car. He well deserved this distinction, for more than any other one man he invented the automobile.

**Barney Oldfield and Henry Ford in the first car that ever traveled a mile a minute**

### Touching Off the Charge

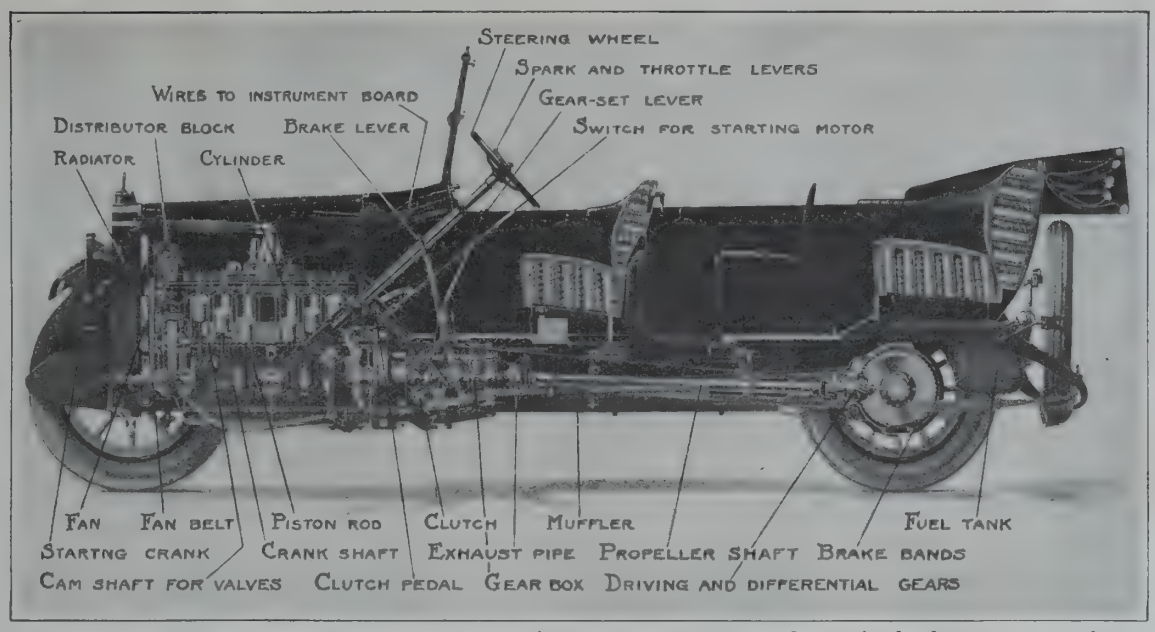
Daimler employed Otto's hot-tube ignition; but before he had it in successful operation on the road, an electric ignition device had been invented by Karl Benz. Benz fitted his engine to a tricycle, and though not exhibited until 1888, it was completely designed as early as 1885. He employed a battery for his current. But in spite of his example, the far less elegant hot-tube ignition persisted in favor among European designers, and it required fresh onslaughts from America, in the shape of the Haynes, Duryea, Olds and other models of the early 90's, to drive it from the field. Even then it hung on, with some of the European makers, until 1900 or thereabouts.

Electric ignition itself presents alternatives between dry battery, wet battery and generator as the source of current;

and between low tension with make-and-break gap, and high tension with fixed gap and jump spark. Each of the early designers worked out his own salvation in this complex business, and it is profitable to mention no names until we come to the inventions of Simms and Bosch that made the magneto the specialized and satisfactory machine that it is. The tendency at first, in turning from the hot tube, was toward dry battery and make-and-break spark; the refinements that make a magneto of the generator were not at hand, and there was hesitation about putting a wet battery on a moving vehicle. The late 90's saw the beginnings of the high-tension development which in the new century was to lead to the magneto, and at the same time found experimenters more willing to give the wet battery a chance. It was not until 1904 or 1905 that the magneto was strictly a high-tension device; and though it was gaining fast, at this date the battery, usually wet, was in the majority. When the Locomobile first appeared as a gas car, in 1903, it was far in advance of its time in carrying two wet batteries for ignition, with a dynamo for keeping them charged. Another look ahead characterized the Peerless of 1907, the first instance which the present writer has found of dual ignition with battery and magneto. On the whole, the tendency until 1910 or 1912 was distinctly away from the battery; and the magneto would doubtless have become universal, had not ignition got snarled up with another question which will be discussed presently.

The transmission of power from the gas engine is a problem wholly peculiar to that engine. For the gas engine will not start without external action; it will not start at all under load; and whatever load it is to carry must be picked up gradually. At the same time, satisfactory regulation of running speeds cannot be got solely by governing the engine, which is fundamentally a constant-speed machine; and the engine will not run backwards, so that reversing must be accomplished, if at all, by means of an extra unit in the gear assembly.

Here we have to introduce another name, with the statement that if Daimler was father of the automobile, Levassor was at least a foster-parent. This French pioneer acquired the French patents of Daimler, with the single purpose of applying them to an automotive carriage. He devised practically out of whole cloth the combination of clutch, gear-box and transmission which has stood ever since as a standard feature of automobile practice, its general features unaltered in the face of multitudinous changes in detail. At the same time he is the responsible author of the convention that puts the engine in front, with its crank-shaft parallel to the long axis of the vehicle.



**A representative 1920 car of the high-priced, high-powered variety, shown in broken-away section to exhibit some of the parts which are to be recognized as characterizing the automobile of today, as distinguished from its predecessors of the horseless carriage and the transition periods**

**The last word of 1920 in big trucks, showing use of giant pneumatic tires**

### The Engine and the Car

We would not be understood, in thus evaluating the contribution of Levassor, as minimizing the ingenious devices which others since his time have added to make the operation and especially the control of the transmission simpler and more effective. The Levassor system, as crystallized by Panhard, called for a separate lever for each speed, or at best for a gear-box permitting passage from a given speed only to the one next above or below. The Packard design of 1902 marked an epoch, introducing the selective gear-set and the single lever in the H-slot operating all gears. During the ensuing eight or ten years the sliding-gear system with four or three speeds and reverse, controlled by gear lever and clutch pedal, together with the equally standard planetary two-speed-and-reverse two-pedal-control system, were developed to their present final form. But it was not until about 1910 that the left-hand drive first assumed a dominant position, so that the rather crude expedient of placing the control levers outside the car in order to have them at the driver's right might be eliminated, at least as a characteristic of American cars.

Otto's original engine was of a single cylinder, as was Daimler's and apparently all the others of the period. But the single cylinder with the four-stroke cycle means that the crank-shaft must revolve twice for each power stroke. An effort to avoid this by means of a two-stroke cycle appeared for a time destined to succeed. At least one of the American pioneers—Elwood Haynes—started with it; but largely by sheer accident, it was shelved in favor of the four-stroke cycle with multiplication of cylinders, which became universal. It was not at first apparent that this would go beyond the point of two cylinders, or at the very most four. In 1902, for instance, the Packard and the Knox were

# Seventy-Five Years of Pure Science

## Some of the Things We Know Today That Were Not Suspected When the SCIENTIFIC AMERICAN Was an Infant

IF we compare the state of science today with that which existed in 1845, the first thing that comes to our attention must be the utter poverty of equipment of the former date as compared with the latter. In good truth the scientist of today ought to get results that were far beyond the reach of his grandfather, for he has tools of a character and of a sensitivity which his grandfather could never have pictured in his wildest dreams. It would be quite out of the question to catalog these; but we may at least mention a very few of the ones whose contribution to scientific advancement has been the greatest.

The microscope and telescope existed, of course, in 1845; but subsequent developments in the direction of improving the definition of the image in the former and of increasing the light-gathering power of the latter have almost made new instruments of both. The spectroscope, developed by Kirschhoff and Bunsen in 1859 along lines suggested by Fraunhofer fifty years earlier, is something at which even the present sophisticated age may well gaze in astonishment. That the light impulses sent out by different substances should be of different wave-lengths seems reasonable enough, and we know that if they are of different wave-lengths they must be of different colors. That the temperature and the pressure at the light source should make some difference in the impulses propagated seems equally reasonable; that a relative motion between source and receiving point should alter the apparent character of the received impulses likewise seems within the bounds of probability. But that a single small instrument of simple outlines should be set up which shall so analyze the light thrown into it that a mere scaling off of linear measurements shall at once give full information on all these points, and do this equally well whether the source of the light is at a distance measured in centimeters or in light-years—this really would seem, in the absence of performance, to push credulity too far.

Then, too, the physicist of 75 years ago had to depend upon microscopic scaling off, with all its inevitable errors, to give him minute measurements of dimensions. Today, through the work of Michelson based on the researches of Young of a century ago, we are able to use the wave-length of light as a measuring unit, and by the elegant method of interference fringes force millionths of an inch to stand out, clearly visible to the naked eye. This is a tool of which Michelson's predecessors could have had little or no inkling.

### The Permanent Observation

Another vast advantage of the present-day investigator in any field is that he does not have to make his observations hastily, while the observed phenomenon is occurring, depending for subsequent use upon such of these observations as he is able to remember or to jot down in the few seconds available for this. Automatic and permanent recording, not merely of the investigator's impressions, but of all the facts in the case, is always possible. If it is a matter of telescopic or microscopic or unadorned visual observation, the camera makes the permanent record, or if necessary, the motion picture machine is called in. If it is a matter of sound, the phonograph is at hand. If it is almost anything else in the world, means are always at hand for forcing the phenomenon under observation to impress its peculiar features on an electric current, which in turn records them in the shape of a jiggly line traced on a revolving drum, or in some other way that makes them equally permanent. Then in every case the investigator is able to survey his results carefully and slowly and as often as he pleases, under the most favorable physical and mental conditions, free from all rush and all fatigue; to place the results of many trials beside one another and compare them directly instead of through mere memory; to apply the most excruciating care to the measurements that are necessary to quantitative determination; to refer again and again to the precise records and reproductions of his experimental results during the hard process of drawing general conclusions from these.

In enthusing over the major items, we should not lose sight of the very great importance of the relatively smaller developments. A little thing like the selenium cell, with its ability to translate light into an electric current and reverse the process to get back the original impression in all its details, is of no end of value. The X-ray and the radioactive body are of less consequence as tools than as contributors to new theory on the nature of things; yet their rôle as tools is by no means an insignificant one. The man who constructs a little exploring coil which, by revealing the magnetic structure of a metal part, makes it possible to give that part a searching physical test without the destruction of the tested piece that always follows the older and cruder method of finding the breaking point by breaking, has given science a new tool of great power. The pyrometer furnishes a means of measuring high temperatures, the electric furnace a means of producing them, that were quite beyond the science of 75 years ago. At the other end of the temperature scale we have the work of Dewar, who shows us how to create an unprecedented degree of cold and how to study what takes place at these low temperatures. And so it goes; every branch of science has made enormous instrumental advances in the past seven decades.

*IT is a very large order to attempt the characterization of the entire scientific achievement of seventy-five years; it is obviously impossible save where the developments of the period considered show sufficient unity to make it possible. To an extraordinary degree the seventy-five years of the* SCIENTIFIC AMERICAN'S *life show this unity; and the word that describes their trend is* GENERALIZATION. *The whole tendency in every field of science has been to include more and more apparently isolated phenomena under a single broad statement, and to show that the things in this universe that are really unrelated are amazingly fewer. And no demonstrable end to this is even yet in sight!*—THE EDITOR.

### Laying the Foundations of Modern Physics

It is largely as a result of all this marvelous equipment developed since 1845 that one may survey the whole field of science and find hardly a single part of that field which has not been completely dug up and planted afresh in matters of fundamental theory during these 75 years. In the forties, for instance, the science of physics in so far as its elementary concepts are concerned was in a state of confusion. Mayer and Joule had just given to the world their determinations of the mechanical equivalent of heat, thus laying the cornerstone for the entire structure of the modern physics. It is difficult to conceive how physicists before 1842 made any progress at all, in ignorance of the relation between work done or energy employed, and heat produced. But even for many years after 1842, in one fundamental point there existed hopeless confusion, on account of the want of an adequate distinction between force and energy. Physicists had gradually acquired the doctrine of the indestructibility of energy; but this was expressed in terms of the so-called law of the conservation of force. Promulgated as one of the triumphs of science, this supposed law was far from satisfactory. The troubles of scientists in trying to reconcile this pronouncement with the facts, their comments and explanations in this connection, make curious reading today when we know that force can be created and annihilated at will, when we have learned to distinguish definitely between force and energy. But after years of work the distinction was formulated and a threefold system of units established for physics, the members being force, work and energy. These were definitely distinguished each from the others; and at once the great doctrine of the conservation of energy, unproved though it be, obtained universal acceptance by men of science and today is universally used as a working hypothesis, with proper modifications in the light of the latest developments.

It is impossible to dwell too strongly on this major achievement of the physics of the fifty years from the forties to the nineties. Until force was adequately distinguished from energy the doctrine of the conservation of energy could not be used, and it is precisely on this doctrine that the whole of the modern physics is constructed. It would be fair to term the theory the greatest discovery of the century in physics, and to name Lord Kelvin, the man who had most to do with its precise formulation and general acceptance, as the foremost physicist of the century—or at least the one who has left the deepest imprint on his science.

This, however, is but one thing that has happened to the physics of 1845. At that date the work of Young and Fresnel was sufficiently old to make the wave theory of light universally understood and universally accepted. And since the doctrine that light is a wave motion called for a medium for the waves, the luminiferous ether had been invented—invented seems really the word, since direct experimental evidence of the ether's presence was lacking from the beginning and has remained lacking. It remained for the decade of the fifties to put to the fullest use this perfectly continuous and perfectly incompressible and perfectly rigid and perfectly elastic medium which the physicist had postulated, by making it carry the electric current as well, in the shape of the waves which Clerk Maxwell indicated as the basis of this current. And where Clerk Maxwell had suggested the obvious conclusion to be drawn from this that light waves and electro-magnetic waves and presumably other yet-to-be-discovered waves were fundamentally the same, differing only in wave-length, it remained for Hertz to prove this, and to give real form to the very elegant conception of a long series of waves, substantially identical in nature, running from electric impulses hundreds of yards long, down through the shorter and shorter waves of wired circuits, of radiant heat, of visible light, and finally of the invisible ultraviolet portion of the spectrum that carries the wave-length far below the fifty-thousandth part of the inch. This generalization of many apparently diverse phenomena under a single caption, despite the atrocities that have been committed in its name by those who failed to understand its proper limitations, was a tremendous step in advance, and one thoroughly characteristic of the period in which it occurred.

The twenty-five years since the appearance of our fiftieth anniversary number have been almost as sharply marked off in the history of physical science as they have by the golden and the diamond jubilees of the SCIENTIFIC AMERICAN. For where the fifty years had been devoted to a laborious building up of the two generalizations outlined above, the twenty-five might well appear, to one not thoroughly alive to the full significance of what was being done, to be given over to efforts to tear down these generalizations. The older members of our staff remember well the opening gun of this campaign; in December, 1895, they participated in an informal editorial conference, at which the question was discussed whether to accept or to reject the wild yarn that had come over the cable from Germany to the effect that Professor Roentgen had discovered a new kind of light to which many substances ordinarily opaque were more or less transparent. When fuller details had come through, and the scientific world was able to assure itself that this extraordinary result was a fact, the tendency was generally to assign the X-rays a place in the table of wave-lengths, putting them at the extreme point of the short-wave-length end. But they were troublesome creatures; they seemed at the same time to be waves and not to be waves—to be at once electrical and material in nature. And here the physicist would have been held in suspense for a long time, had not the chemist been unexpectedly precipitated into the problem with him.

### Ordering the Elements

The decade of the 40's had found the chemist just come into undisputed possession of two tools of the greatest importance—the concepts of the atom and of the molecule. The very clear notions of how and why compounds are formed which resulted from these ideas, and from the knowledge of valency developed during the 50's, led to a precision in analysis and in terminology that had always been lacking. It led at the same time to clearer ideas on what constituted an element, and to the discovery through analysis of a number of new elements, extending the list of these to something like seventy. It made it possible both to distinguish with certainty between atomic and molecular weights, and to determine the former with greater precision than ever before.

As a direct consequence of all this Newlands in England, Hinrichs in America, Meyer in Germany, and Mendeleef in Russia had their attention called to a mathematical relationship which, though rough, seemed clearly to exist between the atomic weights.

Mendeleef was most successful in working out this relationship, and in showing that when the elements were arranged in groups with attention to atomic weights, physical properties recurred in a most striking manner. It is his name that is associated with the periodic law which he formulated, and which constituted the first of the great chemical advances of the period we are discussing.

On the surface this looked more or less like a step backward, a return to the days of the man who insists that there must be only seven planets because seven is a perfect number, or that there ought to be some connection between the arrangement of the seeds in an apple and the vertices of that particular one of the regular polyhedrons which strikes the individual fancy as most beautiful. But while many chemists were inclined to dismiss it with a shrug as being of such caliber, it did not warrant this summary treatment. It can be accepted as entirely rational that there should be such a connection as Mendeleef discovered running through the atomic weights and the properties of the elements—if only we are willing to interpret this state of affairs as indicating that the elements "are not separate bodies created without reference to one another, but that they have been originally fashioned, or have been built up, from one another [or from some common infra-elementary material] in accordance with some general plan." This was the big idea behind the periodic system, and this was the idea which the chemistry of the latter half of the nineteenth century, following that system, developed. It was an idea wholly foreign to the chemistry of 1845, and would have been regarded by preponderant opinion of that date as a survival of or a reversion to the concepts of alchemy. Its acceptance, with all the implications regarding the eventual possibilities of transmutation of some sort, is the logical outcome of the trend taken by experiment and discovery, and constitutes easily the major feature of 75 years of chemistry.

### Matter and Electricity

The major feature, perhaps; but by no means the climax. This came in the chemical world, as in the physical, more or less as an electric shock; and this in spite of the fact that just as Crookes and others had shown results largely anticipating those of Roentgen, Becquerel and others had really paved the way for the Curies. The precise terms of the discovery of radium, again like that of Roentgen, were for some time in doubt; it was not immediately clear whether radium gave forth energy alone, or matter alone, or an ambiguous combination of the two; nor whether it did this with or without permanent loss to itself. Accordingly there was a great deal of concern lest the law of conservation of energy, and even that of conservation of matter, should be shown to fail. Eventually the new discovery was boiled down to rock-bottom facts, collated with the X-ray development, and used as the moving force in further investigations designed to clear up the obscure points; and chemists were then in a position to wrestle with it in the search for its true significance.

There is no space here for any account of this strugle, but the most probable conclusions that have been drawn out of it must be set down as the summation of the physical and chemical development of 75 years. For these conclusions bring together the suggestion forced upon the physicist that matter and electricity are in some way related, and that forced upon the chemist that all the elements are in some manner of the same stuff. Without troubling ourselves too much about exact definitions of "nucleus" and "electron," "electricity," and "matter," it appears that the atom is composed of a nucleus that is mainly matter and one or more electrons that are mainly electricity. Presumably the nucleus and the electrons are identical for all atoms of all elements. With perhaps a little less confidence we may say that presumably some further facts will come out that will show a further degree of identity between nucleus and electron, between matter and electricity. For the present, if we cannot say that matter is electricity, we may at least assert with confidence that the distinction between different forms of matter is wholly an electrical one. And the observed facts of radio-activity and its allied phenomena are very nicely explained by assuming that the electrons are able to detach themselves and travel about "on their own" with some freedom under appropriate conditions.

A further development in line with this has come, in the immediate present, from the field of pure mathematics. It is altogether too early to attempt to place the Einstein theories in their permanent place. It is not too early, however, to say that these theories indicate a unity between apparently diverse things such as had never before been suspected. It shocks our sensibilities to be told that energy and matter are identical to the extent that we may write an equation showing how many ergs it takes to equal one gram; and that time and space are identical to the extent that we may write another equation showing how many seconds are the equivalent of one centimeter. Nevertheless, this is in direct line with the whole tendency of nineteenth and early twentieth century science, which has moved always in the direction of generalization, always in the direction of revealing that things previously supposed to be different are in reality not so.

The pure science of today is the applied science of tomorrow; hence one is somewhat in doubt as to just what may properly be included under the title of this article. It seems fair enough to say that pure science is science for its own sake, the desire to know for the mere sake of knowing, without any question of possible applications to the affairs of ordinary life. In this sense electricity was once a pure science, but today it is anything but that—its every fact and principle are put to work smoothing the path of the human race. But there are still pure sciences, sciences that are pursued just for the sake of driving the facts to their ultimate refuge. Of course the astronomer's findings are put to daily use in the determination of time and direction, and the geologist's are applied in the search for oil deposits, and the biologist's in plant and animal breeding; but this is something that the astronomer and the geologist and the biologist cannot control. There should not be great difficulty in steering a straight course between the pure and the applied; and surely astronomy is the science which is pure to the last degree.

### With Spectroscope and Camera

The astronomer of 1845 could turn his eyes on such a glorious past that he might have been pardoned for lack of confidence in his future. The century immediately behind him had been one of extraordinary achievement; but the invention of one instrument alone sufficed to enable the problematical future wholly to eclipse the past. The astronomer today turns his spectroscope upon a given star, and tells us precisely what chemical elements are present there, the approximate temperature and pressure under which they stand, whether the star itself is old or young as star-life goes, what stages it has been through and what it has yet to undergo, and how fast it is moving toward or away from us. On top of this he can usually manage a pretty shrewd guess as to how large and how bright it is and how far away from the earth. The astronomer of 1845, if asked for these data, would have protested that he could get them only by visiting the star in question. But today we bring the star into our laboratories here on earth, and achieve the same result that would be effected by going to the star. From an imaginative viewpoint, this might fairly rank as the most amazing thing in all science.

*SPECTROSCOPE and camera are merely two of the most vitally important, the X-ray tube one of the most spectacular, of thousands of instruments, scientific and practical, which have been placed at the disposal of the scientist since 1845. It is with these instruments that he has been able to make the tremendous advances that this story endeavors to record in barest outline; and no survey of the period would be complete that did not place the utmost emphasis upon the fact that the past seventy-five years have been an era of extraordinary instrumental development.*—THE EDITOR.

Hardly less important to the astronomer than the spectroscope is the procedure now opened to him of permanently recording—not merely the observations which he might have made, but billions upon billions of observations which, unaided by the camera, he would never have had time or ability to make. Tentative efforts in this direction were made by Arago, in France, and by the senior Draper, in America, in 1839, just before our 75 years commenced to run.

Real success waited until 1880, when the junior Draper in this country and Gill in South Africa made the first adequate telephotographs, taking as their subjects a nebula and a comet respectively. Today star plates by the thousands are in existence, covering all the heavens and all the time since the beginning of the process. No other method is seriously used for the exploration of the sky. For to the advantage, already discussed in connection with the general case, that it gives a permanent record, it adds a second, that this record can be as complete as desire and weather permit; and a third, that the camera is a better observer than the human eye. A single observer with an equipment of cameras is limited, in the amount of material which he can accumulate for future study, only by the number of telescopes available. And when we look through a telescope, with the trifling reservation that concentration of attention on a given part of the field may help a little, we see at once all that we are going to see; whereas the longer we follow a certain bit of sky with the camera, the more stars will, by the accumulated effect of the minute beams of light which they throw upon the plate, make an impression which shall rise above the threshold of microscopic visibility. When the astronomer examines, with a high-power microscope, a photographic exposure of several hours, he is going to see uncounted thousands of stars that no telescope will ever reveal to his eye. With this increased power of observation, and an automatic memory that extends back at least twenty years and is able to recall for him anything that he may wish to know about the appearance of any region of the skies at any date during that time—well, small wonder that he is able to extract from the stars secrets which must have seemed forever unattainable to the astronomer of 1845!

### The Riddle of the Universe

The photographic camera and the spectroscope have worked together in new attacks upon that fundamental question of the universe—whence, when, how, came the stars and the planets? The mathematical physicist too brings new resources of calculation to bear upon the problem, and is able to tell us that Laplace's nebular hypothesis, which our grandfathers considered as absolute truth and the crowning achievement of their cosmic science, is simply foolish, in that incandescent gas never does and never can behave in anything like the manner which this hypothesis demands. With this means of confining himself to physical possibilities, the astronomer has now a fairly definite idea of the course of stellar evolution and decay, and will point to this and that nebula and star and star cluster as illustrations of the several stages. And where the astronomer of 75 years ago thought he was on the point of placing dimensions to the universe, there has been a curious double overturn of opinion. Bigger telescopes and the camera so extended the visible field that no more than ten years ago a competent writer very properly said that all previous inferences as to the limitations of the sidereal system had been discredited, and that in spite of the wonderful instrumental advances, knowledge of the exact form and extent of the universe seemed less attainable than in the first half of the nineteenth century. Today, however, there is good ground for the belief that a concerted attack on the problem, with every mathematical and instrumental resource employed to the full, has at length struck bottom, and that as a tentative estimate of the extent of starry space we may set down some such figure as 300,000 light-years—which sounds much more impressive, though at the same time more meaningless, if we translate it into 2,000,000,000,000,000,000 miles.

The astronomer has collaborated with the geologist in estimating the time necessary for the earth and the rest of the universe to have passed through the various stages of which legible records remain in the rocks and in the skies. It may be laid down as a general principle that each generation since 1845 has felt obliged to throw out of court, as hopelessly inadequate, the most liberal estimate that the preceding one felt justified in making. In 1845 there were plenty of people who did not feel it inconsistent with the scientific viewpoint to believe that the universe was about six thousand years old and to set a date for its creation little if any less absurdly definite than the celebrated statement of the satirist to the effect that it took place at 10 A. M. on Friday the 16th of March in the year 4004 B. C.

Today it is quite out of the question to lay down anything approaching a definite consensus of opinion as to the age of the universe; figures ranging from a hundred million to a billion years are laid down as the lower limit and there really does not seem to be much that can be said definitely on the subject, except that, subject to correction by Professor Einstein, eternity is a long, long time, and that the universe has doubtless used the best part of it in coming to its present condition.

# The Mastery of the Skies

## How the SCIENTIFIC AMERICAN Has Been Privileged to Chronicle the Development of Airship and Airplane

**Lilienthal, the German experimenter who discovered the means of controlling the balance of flying machines, and one of his many gliders with which he made his gliding flights**

THE Burton family, encircling the fireside, read with unconcealed wonder the account of a hollow globe of oiled-silk filled with hydrogen gas, thus giving it a sufficient buoyancy to travel through the air. And they marvelled still more at the spindle-shaped saloon, suspended beneath the balloon, carrying 5,000 pounds of passengers and luggage. Twenty-five passengers in a balloon traveling at 100 miles per hour!

What of it? Nothing alarming or startling, in view of our present-day achievements. But the foregoing-mentioned facts were being read in the SCIENTIFIC AMERICAN of September 18th, 1845. Visionary as such a scheme seemed at that time, the editors of this journal had the foresight and courage to give it the stamp of their approval. They held that the seemingly impossible thing could be done, given the proper time and development which must necessarily precede any epoch-making invention.

Were they correct? History speaks for itself. Seventy-five years later, or to be exact, shortly before the dawn of July 6th, 1919, the Editor-in-Chief of the SCIENTIFIC AMERICAN stood out on Roosevelt Field scanning the early morning horizon for the coming of the monster dirigible, which was to mark the completion of the first westward transatlantic flight. Later, as the huge British R-34 dirigible strained at the hundred cables which moored her to Long Island soil, the SCIENTIFIC AMERICAN might well boast of a vision come true. For the R-34 in 108 hours traveled 6,300 air miles from East Fortune, Scotland to Mineola, Long Island, due to adverse winds. And on the passenger list were thirty officers and men, and a stowaway!

### The Path of Least Resistance

Always has it been man's ambition to fly with wings, emulating the easy flight of the bird. But man soon learned to his sorrow that he had not the muscular power to flap a pair of wings of sufficient spread to carry him through the air. And in the absence of any other form of motive power, man naturally gave up the attempt for the time being.

The free balloon, invented in 1783 by the brothers Joseph and Etienne Montgolfier at Annonay, France, proved to be a simple way of overcoming the pull of gravity which holds us hard and fast to the ground. Immediately men in many countries took up the balloon as a thing for speculation and experimentation. The heated air of the Montgolfier balloon was soon replaced with hydrogen, thus marking a very material step forward in the art since this gas lifts about 68 pounds per 1,000 cubic feet as against some 10 pounds for the highest temperature that is practical for a hot-air balloon. The use of coal gas for inflation, first made by George Green, an English aeronaut, in 1821, constituted another important advance; for though coal gas lifts only about 35 pounds per 1,000 cubic feet, its production is very inexpensive and its use sufficiently satisfactory for sporting purposes and aerial exhibitions.

John Wise, America's pioneer balloonist, invented in 1844 the rip panel. This is a ribbon covering a vertical seam in the upper half of the balloon, which, on landing, can promptly be jerked off to allow instant deflation and thus prevent dragging by the wind. This last invention virtually closed the experimental era of the free balloon, for this has not undergone any notable change in construction during the last eighty years.

The modern free balloon has a bag made of rubberized fabric or varnished silk and is equipped with a wicker basket in which are carried various instruments for recording barometric pressure and altitude, a compass, maps and ballast. Its size varies from 9,000 cubic feet to 80,000 cubic feet; this is the average, for much larger balloons have been built and successfully operated, such as the German "Preussen" in which Prof. Berson and Dr. Suring rose in 1901 to the highest elevation ever reached by a balloon—34,430 feet, or nearly seven miles. This balloon had a capacity of 300,000 cubic feet. Again, the largest hot-air balloon ever built was "Le Flesselles," which was launched at Lyons, France, in 1784 and measured 100 feet in diameter and 130 feet in height. Its volume was 590,000 cubic feet.

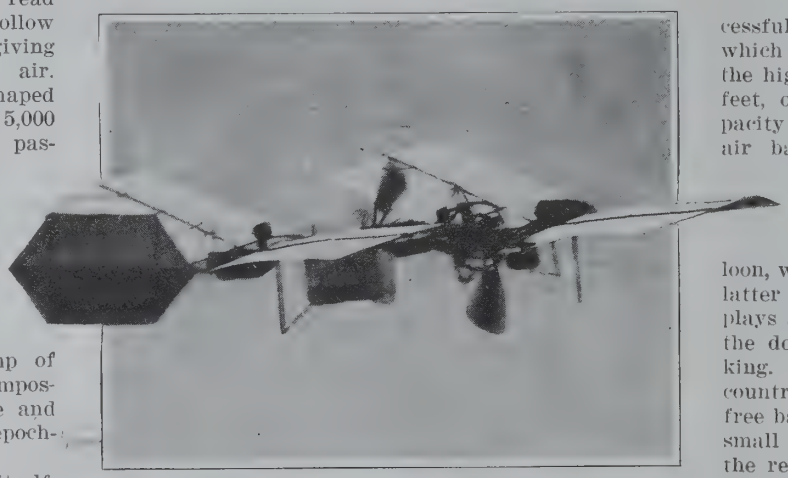
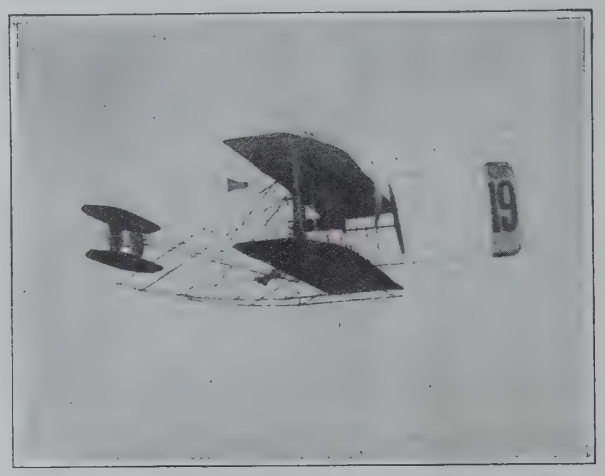
**The "June Bug"—the first machine built under Curtiss's direction, which, on July 4th, 1908, won the Scientific American Trophy for first public flight of one kilometer**



**The man-lifting monoplane built by S. P. Langley, in 1903, and which, but for its defective launching device, would have flown under control**



**One of the early Wright biplanes flown in 1908, both here and abroad. This machine was launched by means of a catapult and rail arrangement**

Despite the development of the dirigible balloon, which is a natural outcome of the free balloon, the latter has still a very definite field of usefulness. It plays a prominent part in the field of sport; indeed, in the domain of sport the free balloon has been called king. Annual competitions are held in the principal countries among the foremost balloonists. Again, the free balloon is used in scientific research, in which case small balloons equipped with scientific instruments of the recording variety are used to great advantage for investigating the constitution of the higher atmosphere. Some of the so-called sounding balloons have reached astounding altitudes; the world's record belongs since 1911 to an Italian sounding balloon which rose to an altitude of 114,900 feet.

### The Gas Bag and Modern Warfare

During the Civil war and particularly during the Franco-Prussian war the free balloon played an important part in the operations, thus establishing itself in the service of the soldiery for all time to come. The siege of Paris in 1870-71 brought forth the free balloon as a satisfactory means of transportation for passengers and dispatches over the German forces. By means of free balloons some 164 passengers were carried out of Paris, together with 3,000,000 dispatches. Out of 66 balloons, only five were captured by the Prussians laying siege to the city, and two were lost in the Atlantic. In fact, so great was the moral and material success of this enterprise that Bismarck threatened to shoot every aeronaut as a spy, and Krupp produced the first anti-aircraft gun.

The wide sweep of the horizon which a balloon affords to its occupants marked this craft upon its very inception as an ideal instrument for military observation. But as the balloon always follows the direction of the prevailing wind it proved necessary to secure it to the ground. In this manner came about the captive balloon. Originally, this was nothing more than a spherical balloon which was attached to the ground by means of a cable.

For the Paris Exhibition of 1878, the Frenchman, Giffard, built a gigantic sight-seeing balloon. This craft, which had a volume of 882,500 cubic feet, carried thirty-eight passengers at a time to a height of 1,600 feet, and was hauled down by means of a 300-horse-power steam winch. This balloon has remained the largest spherical of either free or captive type.

The defects of the ordinary captive balloon were overcome by two German army officers, Captains Parseval and Sigsfeld, who

**Zeppelin L-72, one of the present-day rigid dirigibles capable of crossing the Atlantic. This design, the outcome of the war, no doubt is the forerunner of the commercial dirigibles of the near future**

**British airplane mother ship "Furious," showing the flying-off deck forward and the landing platform aft. The airplane, it will be noted, lands on the platform, runs along onto inflated corrugated stopping cushion, and is brought to a dead stop by the safety nets. The airplanes are housed below**

produced in 1893 the so-called kite balloon—a craft which has proved so successful that it is now recognized to be an indispensable observation agent of every up-to-date army and navy.

The kite balloon consists essentially of an elongated gas bag which is divided into two unequal portions, the larger of which (comprising about four-fifths the total volume) is filled with hydrogen, the remaining one-fifth constituting the ballonet, or air cell, and this is automatically inflated by the wind through a convenient aperture. The ballonet creates within the gas-bag an excess of pressure equal to the pressure of the wind plus the static pressure of the hydrogen, thus enabling the balloon to maintain its shape regardless of any wind the mooring cables can withstand. As air is heavier than hydrogen, the ballonet causes the balloon to assume an inclined position which enables it to counteract the depressing tendency of the wind. In order to keep the craft always head-on to the wind, a sausage-shaped pneumatic fin is fitted to the rear of the envelope, which is inflated the same way as the ballonet; longitudinal stability is further insured by lateral sails and a device similar to a kite's tail.

As a fire-control station for military and naval operations, the kite balloon far surpasses the airplane, for it affords a steady platform wherefrom field glasses or telescopes can be used to great advantage.

In the Great War the kite balloon was used on practically every front. On the Western front alone hundreds of them dotted the rears of the Allied and the German lines. Fortunately for the occupants of kite-balloons, who have no means of defending themselves against airplane attacks, suitable parachutes have been devised which permit them to jump out of the fired balloon and make their way to the ground in safety.

A great improvement was achieved in the performance of observation balloons in 1916, when Captain Caquot of the French Army, invented the kite-balloon bearing his name. This craft has a streamline shape and is fitted with three pneumatic fins at the rear, which do away with the cumbersome fittings of the German balloon. The Caquot balloon can stay aloft in much higher winds and possesses greater stability than the Parseval; its use proved such a success in the war that all the Allies adopted it and the Germans promptly copied it.

Put a power plant into a suitable free balloon and you have a dirigible. So it is quite obvious that the free balloon, sooner or later, gave birth to the dirigible of later-day aviation. And with the introduction of a power plant the balloon became a more positive means of transportation, since it no longer depended upon uncertain winds to take it in any direction they might elect.

### Free Balloon + Power Plant = Dirigible

The basic elements of an airship are (1) an elongated gas-container, called *envelope*, streamline shaped in order to attain the greatest speed with the least expenditure of motive power and stability when under way; (2) one or more cars containing the power plant, the fuel supply, the crew and the passengers, as well as a commercial or military load; (3) a system of connection between cars and hull; (4) such means as will ensure the permanency of the hull's shape; and (5) such means of control as will effectually regulate the longitudinal and vertical equilibrium.

The dirigible more than any other modern machine represents the collaboration of almost countless inventors extending over several generations. Indeed, no one man can be accorded the credit for the dirigible. However, three men may rightly be considered as the founders of the science of airship construction. These were: General Meusnier, of the French Army, who in 1784 laid down the fundamental principles of the non-rigid airship; Colonel Renard, also of the French Army, who designed and built in 1884 the first airship that conclusively demonstrated its ability to navigate the air in any direction desired by the pilot; and Count Friedrich von Zeppelin, a German cavalry general, who devised in 1900 the rigid airship and brought it through persistent work to its present stage of development.

The space allotted to this broad subject of aviation does not permit us to enter into an exhaustive study of dirigible design and construction, but suffice it to say that there are two main classes of dirigibles, the rigid or structure airship, in which the permanency of the bag or hull is attained by means of a rigid framework covered with fabric which encloses a number of drum-shaped gas bags, and the semi-rigid airship in which the permanency of the hull is insured by maintaining within the flexible envelope a pressure superior to the atmospheric pressure.

# Seventy-Five Years of American Patent Administration

## How the System Has Developed from Small Beginnings, and What It Means to the Nation's Industry

By William I. Wyman

SEVENTY-FIVE years ago the leading industrial country was England. It was in that country that the Industrial Revolution began, due to a series of remarkable inventions of the most fundamental character which originated at about the time of the American Revolution. The inventions by Britishers of the spinning jenny, power loom, reverboratory puddling furnace and steam-engine—all perfected within half a generation—led immediately to the greatest of all changes in civilized history.

### The Industrial Revolution and Human Nature

The Industrial Revolution did everything but change human nature. It radically altered politics and history, and did a great deal to modify the appearance of old Mother Earth herself. England, the scene of this revolution, was its first beneficiary, and three-quarters of a century ago its predominance in industry, commerce and wealth was uncontested. The United States was just feeling its way then in manufacturing and machine production. But in the infancy of its industrial life this country presented a radically new system of patent procedure and protection, which tended powerfully to stimulate ingenuity and advance the United States to the foremost place in invention and manufacture. England originated the patent system, her inventions which caused the Industrial Revolution gave strength and body to the system and in turn made it the occasion for the development of the new era. The United States act of 1836, devised by Senator John Ruggles of Maine, constituting the so-called American method of granting patents, was the first vital departure from English patent laws. This act instituted the present organization of the United States Patent Office nine years before the founding of the SCIENTIFIC AMERICAN and in that short time demonstrated its virtues and possibilities.

The law it superseded and the prevailing procedure in all other industrial countries were based upon the "registration" system of granting patents without scrutiny of operativeness, examination of novelty or demonstration of invention. Except as it was made more effective by minor changes, the act of 1836 remains in larger outlines in the law of today; and except for alterations which shall more effectively carry out its purpose and principles, it will persist in the systems of the future. While the law did not fulfil the complete hopes of its creators, it was a pronounced step in the right direction and a decided jump in advance not only of anything that had previously existed, but that had ever been proposed. It was constructive legislation in the highest sense of that abused term. It provided an organization and a mode of procedure for which there were no precedents and presented a positive and clear cut plan for determining patent rights which was absolutely logical and complete and which in its larger outlines provided for every possible contingency. It sharply accentuated the advantages of a proper "examination" system by its vivid contrast with the signal failures of the previously existent "registration" regime. So marked was its success, so closely related to the progress of American industry, so intimately identified with and provocative of the genius of invention, that the so-called American method of granting patents became the standard practice for the whole world to emulate or admire. The only notable exception to this trend, the only highly progressive and powerful state which adheres in entirety to he old 'registration" system, is France. And while there may be no necessary connection between her industrial position and her patent system, it is a fact that she has lost relatively in recent years in the international race for economic precedence. And this in spite of the fact that no people are more ingenious, more original in conception or bolder in action. Even staid, conservative England has compromised and accepted partially the advantages of the examination system. The first country to be industrialized, the first to feel the impulse due to invention, the country to whom the greatest fundamental inventions of modern times are due, England had every reason to remain content with her centuries-old patent system. But she was being passed in the race by the newer industrial nations and she was compelled to alter her system in accordance with the methods which were conferring ascendency upon her competitors.

**The Patent Office Building, the erection of which was begun in 1836 and finished in 1840. This original structure forms the F Street wing of the present building**

### Property in Ideas

For the first time in all history the means for ascertaining and decreeing rights of property in ideas and promoting the objects of a system of patent protection was placed on an intelligent, scientific and adequate basis. Before this time, it was true that some measure of examination prior to the grant was indulged in. In Massachusetts and Connecticut, long before the Revolutionary War, patents were granted by the legislative bodies after a conference with the inventor and a scrutiny of the invention, while under the act of 1790 the Federal Government did the best it could to ascertain utility and the state of the art, but the efforts in these various directions to give valid basis for the patent were spasmodic and fragmentary. No facilities, organization or body of adequate law was ever provided before this time properly to initiate and carry on the "examination" system. This act provided a means for collecting the art, a personnel sufficiently trained to examine the same intelligently, and the machinery and procedure for scientifically endeavoring to give effect to the purpose of the law. That purpose was to throw on the Office the burden which the courts had alone performed, to determine the utility, novelty and patentability of the invention when and where the patent is granted, and, as one writer puts it, "To eliminate litigation 'before it begins.'"

The law of 1836 provided a dignified procedure, gave the grant a *prima facie* standing of validity, and if it did not start this country on its unprecedented industrial era, was at least the most powerful agent in stimulating inventive genius and conserving its fruits. Industrial civilization and invention are inseparable factors. One cannot be comprehended without the other. The present law may be defective and the means to administer it may be inadequate, but the fundamental principles upon which it is based are sound It only needs that it be improved in such detail as necessity indicates to make it the effective instrument that Senator Ruggles perceived it to be for the promotion of the comforts, well-being and progress of a civilized state.

The first commissioner of patents and the man who inaugurated the system under the act of 1836 was Henry L. Ellsworth. During his administration the vulcanization of rubber and the electric telegraph were invented and patented. In the short nine years preceding the 75-year era under discussion such a stimulus was given inventions by the new act as to excite the utmost admiration and wonderment of the Commissioner as he was about to retire from office. In the birth-year of the SCIENTIFIC AMERICAN, the second Commissioner of Patents, Edmund Burke, assumed office, so that the life of this publication is almost coextensive with that of the modern patent system.

A great deal of the early reports of the Commissioners was devoted to presenting agricultural statistics and information interesting to tillers of the soil. By law, the Commissioner of Patents was charged with this duty. Since that time, this activity became vested in a separate bureau and later in a department, while the office to which it was originally an appendage is still an obscure subsidiary to an organism to which it has no functional relationship.

### The Rush of Patent Business

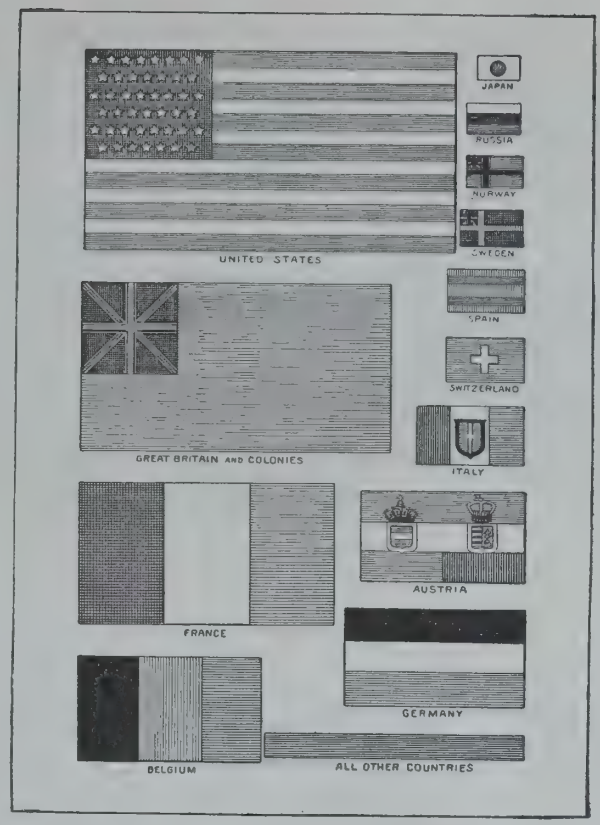
Even in the earliest days of the history of the office, the condition which has since become chronic, manifested itself. In one of his reports, Commissioner Burke complains: "The office is seven or eight months in arrears of its business and is daily becoming more and more embarrassed. Thus, I have in five separate communications to Congress and its appropriate committees within the last two years made full expositions of the embarrassed condition of this office growing out of its greatly increased and increasing business and the inadequacy of its force to perform its duties."

The fact is that the business presented to the Patent Office has always run ahead of its facilities of performance. Public opinion has failed to recognize the stimulating effect upon invention produced by the patent system and the excessive demands made in turn upon the office by the production of such stimulus. There has been a constant lag between the necessity of giving the office support and the furnishing of the required assistance.

In 1851, in the annual report of the Commissioner, were published the beginnings of the present Rules of Practice. In that year, also, the reviews of the advances in the arts by the examiners were omitted in the annual reports. These reviews were comprehensive summaries of the inventions patented during the year and were attempts to appraise and analyze the different contributions of the patentees. They indicated much labor and enthusiasm and gave testimony to the extreme regard the examiners must have taken in their pursuits and the wide scope of their interests.

In the year 1852 there were filled 2639 applications for patents. Commissioner Hodges commenting upon this showing said: "Some find it difficult to conceive that this flood of discoveries and improvements is still to maintain its progress. They look for a falling off and doubt whether there is room for the continued exercise of inventive genius. Every step taken, instead of bringing us nearer to the close of our career, does but open new scenes to explore and prepare the way for new triumphs." It was good prophecy, based upon a thorough consideration of fundamental factors, but even this bold seer would have hardly dared to imagine an income of applications thirty times as large in the course of less than three generations.

In 1861, act of March 2, considerable changes in the organization of the Patent Office were effected. A permanent board of examiners in chief was created to hear appeals taken from the decisions of the primary examiners; the present filing fees were established; and the term of the patent grant was extended to seventeen years. Commissioner Holloway, who served during the Civil War, made the pregnant observation in one of his annual reports that the introduction of labor-saving devices through the exercise of invention was the means whereby a million men could be released from industry without a reduction of output. His successor, Commissioner Theaker, speaks in the same tenor when he remarks: "The ingenuity of inventors has attempted, by mechanical means, to so control and operate the various machines with which our country abounds, that they have to a very great extent supplied the places of the persons who were made victims of war."



**Comparative volume of patents granted by various countries, shown by the relative sizes of the flags, up till the time of the world war**

Immediately after the Civil War, the business of the office increased by leaps and bounds. It was a period also of questionable practices and moral lapses in both politics and business, and the Patent Office fell under the spell of prevailing influences. In 1869 Colonel Samuel S. Fisher was appointed, through the recommendation of the Secretary of the Interior Cox, Commissioner of Patents. Colonel Fisher inherited a condition arising from maladministration and rapid growth of the business of the office. He was Commissioner for but one and one-half years, and, although his administration was one of the shortest, it was by far the most fruitful of accomplishment in the history of the office.

Before he entered the Patent Office, chaos had descended upon its administration; its procedure was unscientific, unstable and hopelessly involved; its conclusions uncertain and disturbing; while its functions generally were performed inefficiently and with exasperating dilatoriness. Charges were openly made of favoritism in its conduct, while the public could not free itself of suspicions of dishonesty attaching to its methods.

### A Critical Period

He first addressed himself to the task of improving the personnel of the examining corps. As the so-called "American System" of granting patents is based upon a consideration of the prior art, it is evident that its efficiency is dependent upon the character and qualifications of the men who make the examination. This aspect is the vital factor in the whole theory. Commissioner Fisher sensed its importance at once, and proceeded to introduce a system of selecting appointees which was based solely upon the fitness of the candidates for the designated position. As he stated in his Annual Report for 1869, referring to the qualifications of examiners, "It becomes very important, therefore, to secure competent men for positions of such responsibility. An examiner should be a man of great patience, industry and honesty, of varied and yet thorough mechanical and scientific attainments, with a good knowledge of patent law, and a mind capable of the nicest discrimination. Though many men offer themselves for the position, but few are fit to fill it."

The tests he constituted were probably the first ever established for entrance into the Civil Service that were rigid, searching and competitive in character. They comprised all the elements of the modern merit system and anticipated its general introduction by almost a generation. It was only through the opposition of a public-spirited official now and then who chanced to be in power and who dared to interpose that the logical result did not intervene and disrupt the whole administration of government. One such official was Gov. J. D. Cox, Secretary of the Interior, who had induced Colonel Fisher to accept the Commissionership. The latter knew only too well how important to the industrial interests it was that the work of the office should be conducted by men of technical and scientific capacity and of high character. And in his efforts to provide a personnel of the desired attainments, he was supported without qualification by his immediate superior.

The result of Commissioner Fisher's policy was shown in the character of the new members of the corps, who in all the requirements of the position readily demonstrated a superiority over those in office who had come in under the old order. Secretary of the Interior Cox, who was a powerful barrier to the progress of many a corrupt influence and who was most anxious to improve the methods of government administration, gave his testimony of the effect of the new policy in the Patent Office in the following words: "No one could become even superficially acquainted with the organization of that important bureau without seeing that a spirit of emulation and zeal had taken the place of a listless and negligent performance of duty." In reviewing the history of those days, one cannot but help noting how far we have advanced in the ethics of government administration. Those who are despairing of the capabilities and rectitude of the office-holding class have no basis for their pessimism. On the contrary, there is good ground for optimism. A most casual comparison of conditions then and now shows an immense improvement in the personnel, both in efficiency and honesty, and a decidedly more wholesome atmosphere.

Commissioner Fisher and Secretary Cox were mostly responsible for initiating this movement, which led to such important results in improving the standards of public taste and executive

# The Diamond Jubilee of the Scientific American

## Three Quarters of a Century's Service to the Cause of Invention and Popular Science

Alfred Ely Beach,
a founder of Munn & Co.

SEVENTY-FIVE years ago occurred an event which was to set its unalterable imprint on the history of American invention and American progress — the founding of the SCIENTIFIC AMERICAN. It is doubtful if there are ten other periodicals which can boast so long a life. "Long life" is here used advisedly; for, at the end of seventy-five years we find the same ideals, the same devotion to the production of an accurate scientific and technical newspaper. This publication first started the idea of a service department, and nearly a million readers have asked for information, and rarely have they been disappointed. "Service" is, in fact, the keynote of the success of the SCIENTIFIC AMERICAN; for the cardinal idea is to conduct the paper in such a manner that it shall be of the highest possible benefit to the business man, the inventor, the manufacturer, and the general reader.

From time to time we get requests from institutions of learning for information relative to the early history of the SCIENTIFIC AMERICAN, for class study. This is the highest compliment which can be paid, and it is to give material of like nature that the present brief article is penned.

We celebrate in this issue the founding of the SCIENTIFIC AMERICAN, which took place in 1845. The journal was a weak and puny affair, however, when it was purchased by Orson Desaix Munn and Alfred E. Beach for a few hundred dollars in 1846. The paper was conducted by them as long as they lived, and since then by the descendants of the former partner.

It is logical that the first office should be in the "Sun" building; for the proprietor of that virile paper was Moses Yale Beach, father of Alfred Ely Beach. The first beginnings were small, the page being about twice the size of the present SCIENTIFIC AMERICAN, the whole paper consisting of only four pages. What we call the "net printed edition" was easily carried to the Post Office by one of the two enthusiastic founders. Journals of any kind were a rarity, and a scientific paper a wonder. The slogan of the first issue was that the "SCIENTIFIC AMERICAN is the advocate of industry and the journal of mechanical and other improvements."

Apparently there was not much industry to advocate or many mechanical improvements to record; for the editor found space enough to publish poetry, dissertations on temperance, and brief articles on such curious topics as "The Utility of Tribulations," "The Influence of Fashion," "Street Beggars," "Oriental Servility," and "Church Benevolence." When the SCIENTIFIC AMERICAN was first published the great achievements of the century were Davy's discovery of the electric arc light and of electrolysis; Oersted's and Ampere's electro-dynamic discoveries; Daguerre's method of photographing; Henry's and Faraday's discoveries in induction; and Joule's determination of the mechanical equivalent of heat.

Some of the advertisements afford interesting reading today and are interwoven with the warp and woof of progress. Advertising increased so that an apology was printed for carrying two and one-half columns! Eight lines cost only 50 cents—payable in cash, let us hope. Advertisements could not exceed 16 lines, and cuts could not be inserted at any price whatever.

### How the Patent Department Was Created

Because it was the only scientific paper of its kind the offices soon became a meeting place for inventors. Out of this intimate relation sprang the necessity of creating a special department for inventors, a department to give advice on the patenting of inventions and on patent law. From its very inception that department has proved the most successful patent bureau ever established. Among its clients have been such distinguished men as Samuel F. B. Morse, inventor of the telegraph; Elias Howe and A. B. Wilson, famous for their sewing machine inventions; Capt. James B. Eads, the distinguished builder of the great Mississippi bridge; Capt. John Ericsson, the designer of the "Monitor"; Dr. R. J. Gatling, inventor of the Gatling gun; Peter Cooper Hewitt, inventor of the mercury arc light; Thomas A. Edison, and others too numerous to mention.

Although the partners of Munn & Co. are members of the Bar, the law practice before the Courts is conducted by an associate firm under the name of Munn, Anderson & Munn.

Orson Desaix Munn,
a founder of Munn & Co.

The Scientific American offices at 37 Park Row, from 1859-1882

### The Scientific American and Inventors

Many of the disclosures are of historic importance for example take A. B. Wilson, who came to New York from Pittsfield, Mass., amid the derision of his neighbors. He came to the offices of Munn & Co., who secured for him a patent which served as the foundation stone for the great Wheeler and Wilson industry, and the world first heard of it through the SCIENTIFIC AMERICAN of November 24th, 1849. In his early days came Thomas A. Edison, and in 1877 he one day appeared with a small package which on being opened proved to be a machine and announced itself by saying: "Good morning. How do you do? How do you like the talking box?" The story of "Mary and Her Little Lamb" is not apocryphal, but Mr. Edison's favorite began "A soldier of the Legion lay dying in Algiers." The SCIENTIFIC AMERICAN Editors were among the first to see the electric incandescent lamp; the Edison dynamo, and the kinetoscope, and a score of other interesting inventions.

The inventions of Mr. Alfred E. Beach must not be passed by as they were of considerable importance and included one of the first successful typewriters, and the tunnelling shield which made possible his Broadway tunnel that was built exactly where trains now hurtle through and in and out of the City Hall Subway station on their way to the outlying boroughs. "Rapid transit" was evidently a problem as early as 1845, but 1870 saw the fruition of their dream. The short experimental tunnel was only a block long; but the cars actually ran. It was reserved for electricity to make subway traffic a commercial reality. Probably the pneumatic system would have been a failure, but this idea for rapid transit was thirty years ahead of the times. Thanks to the then all-powerful Tammany Hall, the scheme was defeated and elevated railways were built instead, much to the wrath of the Editor.

The SCIENTIFIC AMERICAN advocated better railways and helped to mold public opinion to such great undertakings as a line linking the Atlantic and Pacific coasts. The Panama Canal was also advocated as far back as 1846.

In 1845 the SCIENTIFIC AMERICAN began publishing articles on the automobile, such as it was then, and year after year space was given to the ideas of inventors who, groping in the blackness of futurity still had a clarity of vision which was phenomenal. It was through the SCIENTIFIC AMERICAN that they learned of the successes, trials, and failures of the pioneers, such as Cugnot, Trevithick, Church and Lénoir. When, at last, in invention's own time the automobile *did* appear it seemed to the readers not like a sudden apparition, but a vehicle with which they had always been familiar. Aerial navigation early fascinated the readers, even

from the first numbers, so that, for over fifty years it was the only periodical that took the airship and airplane seriously. Impractical ideas were freely criticised, and great sums of money were saved by honest advice which often resulted in the abandonment of useless plans.

### The Scientific American Airplane Trophy

With the object of fostering the art of aerial navigation, the SCIENTIFIC AMERICAN offered a magnificent trophy, which is illustrated herewith, under the auspices of the Aero Club of America, and on July 4th, 1908, Mr. Glenn H. Curtiss won the trophy for that year for flying a distance slightly more than a mile in his biplane, "The June Bug," which is illustrated elsewhere. In 1909 Curtiss again won the cup for flying a distance of 25 miles in a closed circuit, and in 1910 he won the cup for the third and last time in connection with his flight from Albany to New York, when he covered a straight away distance of 74½ miles without stop, which was phenomenal in those days. Mr. Curtiss having won the competition for three years secured permanent possession of the trophy.

### The Scientific American and Its Subscribers

From the very inception of the SCIENTIFIC AMERICAN the editor and the subscribers have been more closely associated than is usual, even in these days of paternal magazine editing. The periodical was always regarded by the publishers as something more than a mere commercial venture. They have always felt that they owe a duty to the subscribers, and a duty that did not end in giving an amount of printed matter equivalent in value to the price of an annual subscription. Accordingly, no letter asking the editor for information is allowed to go unanswered. Often the response entails an amount of research worth many times the amount of the subscription.

### The Scientific American as an Educator

For several decades the SCIENTIFIC AMERICAN stood practically alone in the particular field which it covered. Launched in a new country, destitute of great libraries, great museums, or great universities, it served to a limited degree, it may be, but with distinct success, the purposes of all three. Not a few of the men who stand at the head of the great industrial institutions of the United States recall the hopeful days of their boyhood and their young manhood, when their chief source of instruction in the great happenings of that world in which they were about to make venture was the SCIENTIFIC AMERICAN.

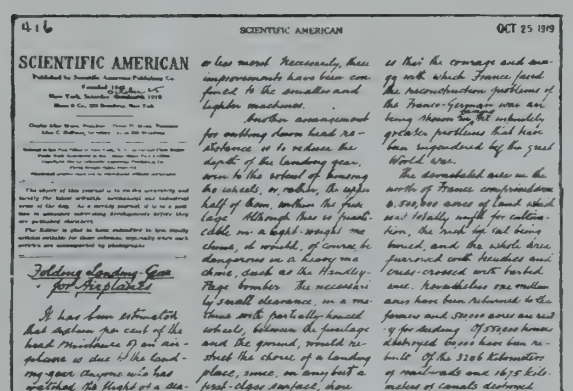
BY COURTESY OF THE "SCIENTIFIC AMERICAN."



SCIENTIFIC AMERICAN

Folding Landing-Gear for Aeroplanes

It has been estimated that eighteen per cent of the head resistance of any aeroplane is due to the landing-gear, anyone who has watched the flight of a dirigible must have noticed how carefully he streamlines himself by straightening out his legs against the atmosphere. It only will be that the action of the birds supported the possibility of doing something to the kind with the landing-gear of the aeroplane. It may be remembered that, some few years ago, the editor of this journal suggested that the landing-gear might be hinged to the fuselage, so that it could be drawn up against the undercarriage by means of a connecting rod and piston, actuated by compressed air.

In the intervening years much thought has been given to this problem, and, today, there are several machines which carry folding landing-gears of more

THE STORY OF THE BARTRAM OAK

HOW A LITTLE EXACT EXPERIMENTAL SCIENCE SOLVED A PROBLEM OF LONG STANDING

By Dr. Arthur Hollick, New York Botanical Gardens

A REPRESENTATIVE GROUP OF OAK LEAVES OF DIFFERENT TYPES

LEAVES OF THE BARTRAM OAK (LEFT) AND OF THREE OTHER SPECIES

**WITH AN EDITORIAL IN LONGHAND AND OTHER LETTERPRESS IN TYPE-WRITING: PAGES FROM A LITHOGRAPHED NUMBER OF THE "SCIENTIFIC AMERICAN" PUBLISHED DURING A STRIKE OF NEW YORK PRINTERS.**

Owing to a strike of printers in New York, over a demand for increased pay, many American papers recently had to suspend publication. The "Scientific American," however, which has never missed an issue in 74 years, adopted an ingenious plan to avoid doing so. A prefatory note in the issue for October 25, four pages from which are reproduced above on a reduced scale, says: "The copy has been prepared by the editors on their trusty typewriters; and from this copy photographic transfers have been made on a lithographic stone. . . . We believe that this is the first time it (lithography) has ever been used in this manner, to produce the inside of an ordinary magazine. In this process the entire page becomes in effect a single illustration . . . We present the editorial page in direct reproduction of the original long-hand manuscript by the senior member of the staff." Some of the stock advertisements appeared in ordinary print, but these were already set up in type before the strike.

**How the Scientific American got along without compositors and pressmen during the printers' strike of the autumn of 1919**

Thousands of men who are now engineers and manufacturers received their first inkling of mechanical or electrical engineering from the pages of the SCIENTIFIC AMERICAN. Thomas A. Edison has related that as a boy he used to walk three miles to the post office every week to get his SCIENTIFIC AMERICAN. For seventy-five years issue after issue has explained with a simplicity that has appealed to every earnest student unfamiliar with the phraseology of more technical periodicals and books how apparatus of all kinds are constructed, and how such devices operate.

### Exposing Swindlers

As the SCIENTIFIC AMERICAN ministered to the intellectual requirements of a pre-eminently practical nation, so it guarded its financial interests when they involved science or machinery. Swindling schemes, based on supposedly revolutionary inventions, are encountered with less frequency than formerly, chiefly because we have a large class of trained technical men to fall back upon for expert advice. Thirty-five years ago it was otherwise. The late John W. Keeley, of blessed memory, who talked with the glib obscurity of an Indian Swami and was possessed of the audacity of a Cagliostro, was the prince of these swindlers. Year after year the SCIENTIFIC AMERICAN ridiculed his "etheric vapor," his vibrators, his resonators, and the mysterious forces that served to discharge his etheric weapons and to operate his engines. The editor took the trouble to build a duplicate of Keeley's "etheric gun," to prove that it was operated by compressed air. When Keeley died in 1899, still gaining the ears of a rapidly dwindling public, still living on the spoils of the mechanically ignorant and credulous, the SCIENTIFIC AMERICAN made a thorough examination of his laboratory at 1420 North Twentieth Street, Philadelphia. Every piece of flooring was torn up ruthlessly and every nook and cranny searched. The investigation turned out exactly as the SCIENTIFIC AMERICAN had predicted twenty years previously. Keeley's "etheric vapor" proved to be compressed air, and the man was proven to be a charlatan. There were other schemes besides Keeley's—all of them forgotten now, but as alluring to the unwary investor. In exposing them the SCIENTIFIC AMERICAN probably saved many a reader from serious financial loss.

### The Scientific American and the War

For two or three years prior to the terrible catastrophe of 1914, the editors had been very much interested in "preparedness," and had quietly amassed a fund of information and valuable data which was to prove of much use in the troublous years to follow. Scarcely had the cables announced the fateful news that Europe was aflame, than preparations were begun to treat the war in an accurate and scientific manner, and every member of the staff threw himself into the work with the greatest enthusiasm. The famous "War Numbers" are still preserved in libraries as among the most valuable of written memorials of the world-war. The sale of the earlier War Numbers was enormous, and helped to educate an entire people into the serious business of war, which was so little understood and which was so vitally necessary. The number of illustrations on war subjects went into thousands, and the best talent in the way of professional soldier and sailor writers was obtained. The entire collection of these thousands of pictures has been given to Princeton University, and the process of transfer is still going on.

Our entry into the war resulted in even greater efforts to inform the American people, and the editorial rooms of the SCIENTIFIC AMERICAN became a great clearing house where meritorious inventions and devices were speeded to the proper governmental agencies, and the merely chimeric plans were discouraged.

### Labor Troubles Are Overcome

Perhaps the most serious mishap the SCIENTIFIC AMERICAN suffered in all the seventy-five years of its existence was the printers' strike in the autumn of 1919. The compositors ceased working almost without notice after the pressmen had struck. If the compositors had not struck it would have made very little trouble; for we were calculating on working the paper by lithography, using the "offset" process for both type and illustrations. Our hopes were blasted, however, when type could not be set. Our editors' minds moved quickly, and in a surprisingly short space of time they evolved a plan which made typesetting in the emergency unnecessary. The matter was first "roughed out" on a typewriter, so that the approximate amount of space could be allotted, and then it was retyped with the same care as a hand compositor used in justifying his lines and spaces. Troublesome "run-rounds" were conquered and even the "fuzziness" of the textile ribbon was obviated by the sub-

# Faith

MEMORY sometimes swings back to days when the automobile was nothing but "another crazy idea." When the few who took it seriously were objects of the misplaced sympathy of friends, and of unfriendly comment by the general public. When the legal rate of speed in many big cities was not to exceed seven miles an hour. When the man whose horse ran away at the sight of a horseless carriage always had the jury with him.

Those early days mean something to us now because to believe in the future of the atuomobile meant a great deal, then. To point a business in a new direction, seaward without a compass, took something more than courage and resource. It took the same vision, the same purpose, that were actuating those who were spending their days in the shop and their nights at the drawing board, producing the very beginnings of a new kind of transportation. It took *faith!*

During the last score of years the automobile industry has made a place for itself from which it can never be dislodged. It has done something more than develop a new mechanism to serve convenience,

# TIMKEN

or whim. *It has produced a new and fundamental transportation method, whether for people or things.*

It has made a daily contribution to the health and welfare of every person who lives in the civilized world. It has made Better Service between men, and between peoples, a fact instead of a theory. It has justified the faith of those who saw in it an agency that would realize the dream of a *Railway Without Rails.*

The reliable passenger car and truck builders, and every manufacturer who produces good equipment for their completion, are in the same business as the railroads. It has taken hard work, a lot of it unseen and unsung, to put them there. Most of those who took off their coats in the early days have never had time to put them on again.

The demand has been insistent for automotive transportation that should be increasingly better and more reliable. Each unit of the industry has had to organize for service. Engineering has made tremendous strides. Production methods have evolved that are the wonder even of those intimately concerned with them. Every day has meant twenty-four hours of progress.

Now comes a further development of the fundamental idea, which will make possible machine methods, and larger harvests, on every acre of farm land, cultivated and uncultivated, in the world today. The opportunity for service which lies before the tractor industry is as magnificent as any American business has ever faced.

It seems a long way back to the days when most people were saying, "the automobile will never work." *But we remember when faith in our product was all we had with which to anticipate the refined, fast-moving, powerful motor vehicle.*

Manufacturers of automobile, truck, and tractor have already surmounted their gravest difficulties. Commerce and industry, and the individual, recognize that the usefulness of the self-propelled vehicle has established it as a utility, and as an essential. The world can no longer get along without it.

***Faith today is founded on fact!***

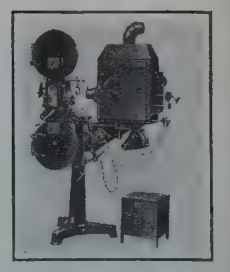
## Some of the Milestones That Accentuate the Development of Amateur and Professional Photography



IT required an exposure of six minutes in strong sunlight to make a portrait of Miss Dorothy Catherine Draper. But that was in 1840, and her's was the first photograph of a human face. Compare that achievement, by Prof. John William Draper, with the remarkable snapshots made by anyone with a two-dollar box camera today, and you have a condensed summary of the development of photography during the past four score years.

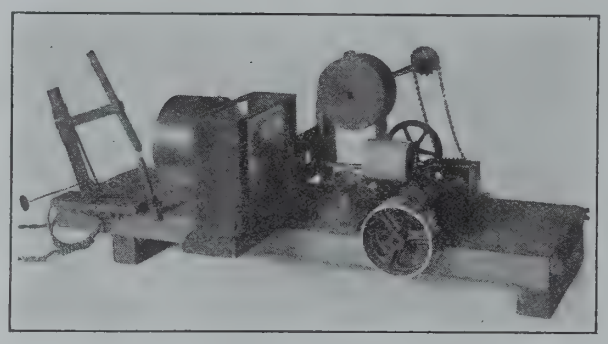
Photography does not start with the work of Professor Draper, nor does it start with Daguerre. Indeed, the origin of photography, or more correctly the origin of the camera, dates back to the middle of the sixteenth century when an Italian philosopher, Battista Porta, exhibited his *camera obscura* to the crowds that flocked to his house in Naples. All he did was to put a tightly-fitting shutter on his window, so that no light could enter except by a small hole which he had cut in the center of the shutter. He did not use a lens; yet the rays of light entering the room showed an inverted image of outdoors on the opposite side of the room. And even Porta's *camera obscura* is not the first attempt at the camera principle, for there are records of previous experiments of this kind.

At any rate, the *camera obscura* was the basis of photography. There remained the problem of recording the image in some suitable manner so that it might be made permanent.

So it may be said that photography proper starts with the work of Joseph Nicéphore de Niepce, who has been called the father of the art. His process appeared in 1824. In the Niepce process a silver-faced copper plate was coated with asphalt dissolved in oil of lavender and dried. It was then exposed to light in the camera, or in the case of an engraving, by superposition. Thereupon it was washed over with a combination of one part of oil of lavender and ten parts of petroleum. The picture was next rinsed in water and dried, preparatory to being placed in an iodine fuming box until the bright silver ground turned black. On removing the part of the asphalt remaining, the lights and shadows of the picture appeared in their proper relation, or instead, the plate was etched and printed as in ordinary etching.

### Daguerre—His Process and His Work

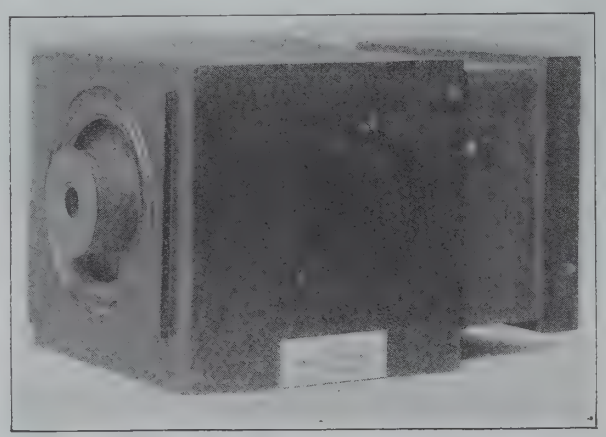
Then came Daguerre, whose name is so well remembered whenever photography is mentioned. It was in 1839 that Daguerre published his process. A copper plate, one surface of which had been silvered and highly polished, was fumed with iodine and then exposed in the camera, followed by the development with vapor of mercury and fixing in a solution of hyposulfite of soda. The solvent action of hyposulfite on the silver haloids was discovered by Sir John Herschel. The exposure required about fifteen minutes. Niepce and Daguerre then collaborated in the development of photography, so that some of the credit of having developed the daguerreotype belongs to Niepce.



This projector, exhibited by C. Francis Jenkins, in 1893, contained the essentials of the present-day machine shown at the upper right-hand corner of this page. Note the carbon arc, condenser, sprockets, intermittent movement and general arrangement. A water condenser was used to reduce fire hazard ever present with exposed celluloid film

**A pioneer machine which marked the beginning of the modern projector**

Soon after this, however, by the addition of bromine to the iodine by Goddard in 1840, and chlorine by



This camera was the first Daguerreotype apparatus made in the United States, making its appearance in 1839. Focusing was accomplished by having the box made in two sections, one sliding within the other

**Compare this early camera with the latest motion-picture camera in the upper left-hand corner**

Claudet in 1841, the plates were made more sensitive; indeed, in the year 1840 we find Dr. Draper making daguerreotype portraits in from twenty to ninety seconds. It was M. Fizeau who discovered that by treating the daguerreotype with double hyposulfite of soda and gold, it was made more permanent and very much more beautiful.

We come next to the calotype or talbotype, the invention of Henry Fox Talbot. Until Talbot's process was published in 1840, there was no such thing as printing in photography; that is to say, but one copy of a picture was made at each sitting, and that was the original exposed in the camera. Talbot introduced the photographic negative from which an unlimited number of prints may be made. According to Talbot's process, a solution of nitrate of silver was prepared, brushed over a sheet of paper, and dried. Then the paper was dipped in a solution of iodide of potassium, washed in water, passed between blotting paper, and dried. This was called iodized paper. When the paper was required for use, it was washed with a solution of nitrate of silver fifty grains, water one ounce, acetic acid one-sixth of an ounce. This was called "Solution A."

"Solution B" was a saturated solution of gallic acid in cold water. The two solutions were mixed in equal parts, just before using. Talbot called this "gallonitrate of silver." The iodized paper was treated with this solution and again dried. The paper was then exposed in the camera and developed with the gallonitrate of silver and fixed in hyposulfite of soda. Talbot found later that, by waxing, the paper negative was rendered more transparent, so that it gave better results in printing.

The use of collodion as a vehicle to hold the silver haloids upon plates originated with Frederick Scott Archer in 1850, although the idea was suggested by Gray the same year. Albumen paper had already been introduced by Blanquard-Everard in 1848.

Various photo-lithograph and other printing processes were invented at about this time, with a number of inventors taking part.

### Better Prints and How They Came About

George Wheaton Simpson is credited with working out the printing-paper process as early as 1861, using collodion for the purpose. Abney, in 1881, worked out printing paper with gelatine. The present developing papers—papers which, unlike the printing papers, do not show the image until they are properly developed, but which are so much faster and easier to handle, requiring only gas light or electric light in place of sunlight—came some time later. One of the most successful of these papers was that of Dr. Leo H. Baekeland.

Carbon printing in its present form appears to be the product of many minds. Mungo Ponton in the year 1839 discovered that white paper treated with a solution of bichromate of potash darkened when exposed to light. The next was the discovery that gelatine, gum and other bodies were rendered wholly insoluble

# Four Important Questions For Every Employer

Above are four stop-you-in-your-stride questions. If you have not read them, do so now. They have an important bearing on your production, your spoilage and your accidents. If your plant is incorrectly lighted, your net profits are being affected by some or all of the above conditions.

Do you realize that an improperly lighted factory costs *more* for illumination than one that *is* correctly lighted? It's a fact. Tests prove it. Here are the figures. Poor lighting is costing you 12% *less* production, 25% *more* spoilage and 25% *more* accidents. Translate this into dollars and you have a cost many times the price of a complete 100% efficient Benjamin Industrial Illumination equipment. In other words, you are paying more for the doubtful privilege of inadequate illuminating service than you would for the best the illuminating engineering world affords. Can you afford it? We hardly think so.

Benjamin Industrial Illumination has revolutionized the illumination in many of America's foremost plants. It has turned inadequate, expensive lighting into efficient, economical illumination. It can do the same for you. Our Illuminating Engineering Department will gladly co-operate with your engineer, contractor or architect in making recommendations that will secure for you all that modern artificial lighting provides. Further information awaits the asking.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

### Electrical Devices

SWITCH.—J. SCHNEIDER, 412 Walnut St., Roselle Park, N. J. This invention relates to high tension switches of the plunger type, its object is to provide a disconnecting switch arranged to combine maximum rigidity with minimum of weght and allow of conveniently opening and closing the switch. Another object is to maintain the opening members in perfect alinement when the switch is opened or closed thus insuring perfect electrical contact. Another object is to protect the contact making parts from moisture, dust, or other extraneous matter and to render the plunger self-cleaning.

THERMAL CIRCUIT CLOSER. — W. P. WEBBER, 147 Hancock St., Brooklyn, N. Y. An object of the invention is to provide a heat-controlled fire alarm device which may be conveniently held either in a vertical, horizontal or any intermediate position such as on a ceiling or side wall, so that said device will be responsive to a predetermined increase of temperature either within a room or between the walls or ceiling or partitions, to cause an electric circuit to be completed.

### Of Interest to Farmers

PLANTER.—F. H. SCHUTTER, Pleasant Valley, Iowa. The invention relates more particularly to planters for planting onion sets. An object is to provide means whereby a great number of onion sets can be planted in a relatively short space of time. A further object is to provide an onion planter that is simple in construction, efficient in operation and one that can be cheaply made.

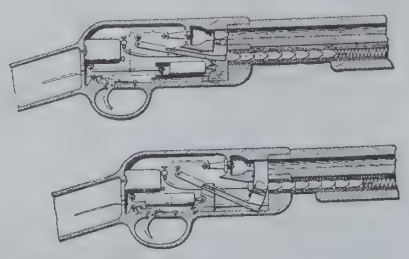
AGRICULTURAL IMPLEMENT. — R. B. MASON, 19 West Patriot St., Somerset, Pa. The invention is adapted for use with a threshing machine. It consists of a sheaf loader adapted to travel over the ground and gather the sheaves into a container. A sheaf distributer receives the sheaves when the loader is backed up to the distributer and the sheaf discharge gate is opened.

DRAFT-COUPLING.—J. W. BULLER, Hillsboro, Kans. The principal objects of this invention are: to provide means for automatically releasing a movable drawn member from power means for arresting the former, and to prevent wrecking a plow when its progress is arrested independently of the tractor means during the progress.

### Of General Interest

TENT AND HAMMOCK.—L. E. TRIMM, 677 E. 21st St., Brooklyn, N. Y. The invention has for an object the provision of a construction wherein the device may be used in its combined capacity as tent and hammock or may be used separately. Another object is to provide a tent and hammock arranged to be supported by ropes to suitable trees or supports, the arrangement being such that the hammock may be used as a bed in the tent or as a canopy or fly for the front of the tent.

RIFLE.—H. H. JONES, Holland, Ore. The principal object of the invention is to provide a simple yet highly efficient and durable rifle which will utilize the forms of expanding



CENTRAL LONGITUDINAL SECTIONS OF THE GUN, SHOWING A BULLET IN POSITION TO BE FIRED, AND BEING LIFTED FROM THE MAGAZINE

gases to drive the bullet from the barrel. A further object is to provide a gun in which the gasolene or other fuel used is mixed with air, and supplied to a combustion chamber at the breach of the gun, thus making it unnecessary to provide cartridge cases for the bullets to contain the explosive powder for impelling them.

PROCESS AND APPARATUS FOR METAL PLATING.—R. J. PIERSOL, Houston, Pa. The invention relates to a process for the plating of one metal with another metal which consists in enveloping the metal with the higher melting point by the fused bath of the metal with the lower melting point, said means being heated *in vacuo* to a temperature between their melting points. The device consists of a vacuum jar, a container placed in the jar adapted to contain a fused material, and means for lowering the second material into the first mentioned fused material.

DISPENSING CAN CLOSURE.—J. H. HOWARD, 2138 Perry St., Jacksonville, Fla. An object of the invention is to provide a device which when operated, opens the outlet of the can, causes a forceful ejection of a portion of the contents thereof and then closes the outlet. A further object is to provide a dispensing can closure which causes a uniform discharge at each operation and prevents wastage through careless operation.

SHELF.—F. GRAMMICH, 499 Vandervoort Ave., Brooklyn, N. Y. The invention relates to a sheet metal shelf so formed that comparatively thin sheet metal may be made to possess the necessary strength to sustain a considerable load. The object is accomplished by folding the sheet metal at one or more points in such manner that it will present members serving to stiffen the shelf as well as to give under support thereto.

HUMIDIFYING APPARATUS.—V. W. McADAMS, 218 So. Clarkson Ave., Denver, Colo. An object of the invention is to maintain a desired degree of humidity in a show case, more especially intended for tobacco, cigars and cigarettes, or the like by automatically increasing the moisture on the one hand or supplying a drying heat on the other hand, the moisture supplying means and the drying means being governed by a hygroscopic controller.

PENCIL SHARPENER.—J. SONTHEIMER, R. No. 5, Lincoln, Neb. The general object of the invention is to provide a sharpening edge in a tubular member ground so that the sharpening edge is presented at the edge of the opening produced by the grinding, whereby the sharpener may be used in different ways for sharpening a pencil. The sharpener is embodied in a tubular pencil attachment having pocket clips so that it may always be ready for use simply by slipping the clip fitting from the pencil.

CLUSTER BACK FOR JEWELRY.—O. P. BAILER, cor. Main St. and Jefferson Ave., Memphis, Tenn. The invention relates more particularly to the cluster back used in setting cluster tops in various mountings. The principal object is to do away with use of a necessity for solder, thus reducing the cost of manufacture. Another object is to provide a cluster back which is interchangeable and can be quickly applied to or removed from any form of setting, and which will simulate the facets of a full gem.

### Hardware and Tools

LOCK FOR METERS, ETC.—H. H. ROE, address Podlashue & Nicholson, 22 Bureau St., Pretoria, South Africa. The invention has for its object to provide locks for a number of special purposes, as for instance, water and gas meters, pressure gages, time recorders, handcuffs, motor car hoods, bicycles and the like; the construction is of few parts and easily operated. Another object is to provide a single key and single hand-operated member, with a manually actuated bolt held normally in locked position and a key operated screw.

VALVE FOR PNEUMATIC TOOLS.—W. S. WHYTE, 1128 W. 14th St., Bedford, Ind. This valve is adapted to be inserted in a hose or conduit to control the flow of compressed air or other motive fluid to a pneumatic drill or the like. Provision is made for the gradual admission of compressed air to the drill to effect a variance in the power stroke of the drill.

WRENCH.—L. DOONAR, Bend, Ore. This tool is specially designed for use in removing the nuts which hold the bearing caps on the connecting rods of an automobile engine and particularly for use in connection with number four piston of a Ford automobile which is known in the art to be particularly inaccessible.

ANTI-RATTLE CATCH.—C. J. HAGSTROM, Maple Ave., Glen Cove, N. Y. This catch is particularly adapted for use on doors, swinging windows and the like. The bolt of the catch is pivoted and is held in normal position by means of a spring. This makes the projecting end of the bolt bear against the socket piece in the jamb and prevents the door from rattling.

### Heating and Lighting

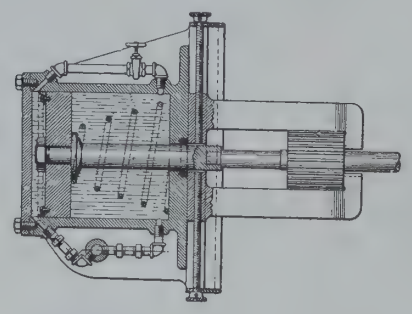
GAS HEATER.—C. M. MOGNI, 325 W. 4th St., New York, N. Y. The object of this invention is to provide a new and improved gas heater more especially designed for use in laundries and other establishments for heating sad-irons and like devices. The heater is arranged to produce an exceedingly intense flame to insure a quick, effective heating of the sad iron.

RADIATOR.—C. C. MANKER, Mayfair Apts., 40 St. James St., Los Angeles, Cal. Provision is made in this invention whereby oil or gas burners may be used in the ordinary steam radiators now in common use for producing a proper steam heat. Means actuated by the steam in the radiator control the volume of oil or gas fed to the heater, thereby producing automatically a uniform heat.

OIL BURNER.—C. C. MANKER, Mayfair Apts., 40 St. James St., Los Angeles, Cal. This oil burner may be applied to various uses, such as cook stoves, heating stoves, furnaces and the like. It dispenses with the use of an auxiliary pressure such as that supplied from compressed air, the arrangement being such that the pressure of the gasified fuel is sufficient to force the gas into the combustion chamber and at the same time to entrain a requisite uantity of air.

### Machines and Mechanical Devices

HYDRAULIC GEAR JACK.—A. W. HILLIARD, R.R. No. 2, Wheelersburg, Ohio. An improved hydraulic jack is provided by this invention adapted to strip or remove a gear, pinion, cam, collar, commutator core, or various other devices from the shaft carrying



IMPROVED HYDRAULIC GEAR JACK

the same. The invention provides adjustable means for engaging and holding the gear or other device against longitudinal movement while the shaft is removed by hydraulic means.

WIRE-DRAWING MACHINE.—D. C. SULLIVAN, G. L. HAWKINS, and W. J. MACMILLAN. Address Almion Engineering and Contracting Co., 25 Church St., New York, N. Y. By means of this invention two wires may be simultaneously drawn with the same source of power. The construction is such as to allow of stopping the reduction and removing either of the wires without stopping the drawing or reducing operation of the other wire.

### Medical Devices

TONGUE DEPRESSOR.—C. MACM. BUGBEE, Springfield, Vt. The invention comprehends a tongue depressor having such form that it may be made up inexpensively and be used for depressing the tongue under such conditions that a thorough inspection can be made at any and all stages of the use of the device.

### Prime Movers and Their Accessories

VAPORIZER FOR HEAVY OILS.—C. C. MANKER, Mayfair Apmt., 40 St. James St., Los Angeles, Cal. The invention relates to vaporizers for heavy oils such as kerosene and the like, for use in connection with automobile engines or gas engines in general. An object is to provide a simple device by means of which the engine may be started on the low grade oils, thereby obviating the necessity of carrying additional fuel, such as gasoline, for starting purposes; the device also dispenses with the ordinary carbureter.

INTERNAL COMBUSTION ENGINE.—R. P. GRIEVE, 327 E. 22nd St., Brooklyn, N. Y. The invention pertains more particularly to a piston construction of an internal combustion engine. It is the object of the invention to improve the construction of pistons in two piston engines in such manner that one of the pistons is adapted to be protected by the other piston. It is a further object to construct a superpiston in such manner that its radiating surface is greatly increased contiguous to the walls of the cylinder in order that the same may be more effectively cooled.

VALVE SPRING LIFTER.—G. T. EUARD, c/o M. R. Deyo, Peoria, Ill. An object of the invention is to provide a device which is especially adapted for use in connection with the valves of internal combustion engines, such as are employed in automobiles, but may of course be adapted for various other valves. A further object is to provide means for lifting the pressure disk on the valve stem against the action of the valve spring, so as not to exert any angular or torsional strain on the parts.

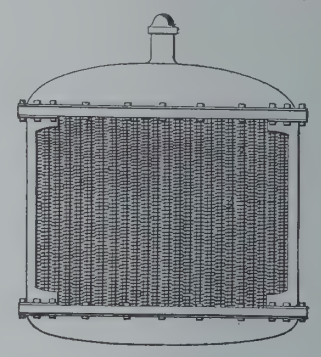
### Railways and Their Accessories

SAFETY DEVICE FOR CATTLE AND RAILWAY CROSSINGS.—J. I. DOMINGUEZ, Calle Maipu 671, Buenos Aires, Argentina. The invention relates to a device for preventing cattle or animals from gaining access to the interior of tracks. The invention essentially consists of a plain grating provided with rotary rollers and so balanced in its conjoint that when an animal should step thereon a part of the device will descend and the animal will recede when noting that it has stepped on a false floor.

CATTLE GUARD.—J. I. DOMINGUEZ, Calle Maipu 671, Buenos Aires, Argentina. This invention relates to a device for preventing cattle or the like from entering the tracks of railways by the openings left at the level crossings. The device provides a grating so held in suspense that the same may shift or oscillate in any direction so as when simply stepping with the foot thereon it will cause the animal to lose equilibrium and getting frightened will withdraw therefrom.

### Pertaining to Vehicles

AUTOMOBILE RADIATOR.—C. COSTELLOE and S. G. STOLL, 560 Morton Court, Hammond, Ind. An object of the invention is to provide an automobile radiator having as one of the prime features, the ability to easily remove



A FRONT ELEVATION

the top and bottom tanks so that the tubes may be readily reached for replacement and repair. Another object is to provide a radiator with means for simultaneously radiating the heat and adjustably checking the flow of the water.

RADIATOR SUPPORT.—A. L. W. OHMACHT, Cresco, Ia. An improvement is provided by this invention in supports for holding radiators in various positions so that any part of the radiator may be brought into position accessible for soldering and so that the hot solder will run into the desired place by gravity.

### Designs

DESIGN FOR A TONE ARM.—M. BORRIS, 2992 W. 31st St., Coney Island, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## G-E Marine Turbines Never Failed in Service

EVER since the turbine won its undisputed supremacy over the reciprocating engine in utilizing steam's force, the General Electric Company has been making turbines extensively for many uses.

***The General Electric Company is the World's Largest Producer of Steam Turbines***

In the war period—April 17, 1917 to November 11, 1918 this Company shipped Marine Geared Turbines for 147 merchant ships. These sets were produced at the rate of one per day during the last month of hostilities, and today 284 merchant ships propelled with General Electric Company's Marine Geared Turbines are plying the seven seas.

***No G-E Equipped Ship was ever Towed into Port Because of Turbine Trouble***

The Curtis Turbine and G-E improved, double reduction two-plane type marine gears stand as

***"The Master Ship Power of Today"***

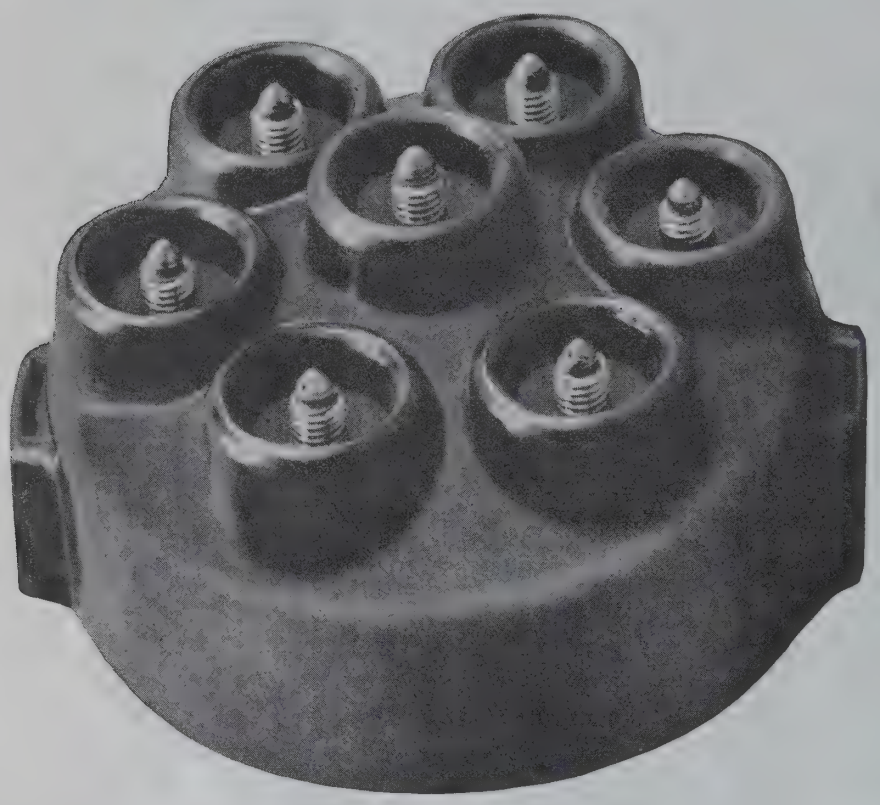
# REDMANOL

REG. U.S. PAT. OFF.

For Perfect Molding



## You can trust it in your product

DAILY the list of REDMANOL users is extended to include more names of national repute. It seems, and rightly it should be so, that the higher the position a manufacturing institution holds, the more ready is it to embrace ideas and materials that mean product-betterment. It is difficult now to mention many lines whose leaders are not users of REDMANOL. The reason: it is the perfect molding compound. Its possibilities of use are limitless. Every day sees new additions. And in everything from ignition systems to bookkeeping machines to telephones to wireless outfits, and in an almost limitless number of other uses, it is ever reliable, always with the qualities listed below, never failing to do the part assigned to it. What is your problem?...bettered product? lessened production time? or lowered costs? Ask if REDMANOL can be used in your product.

*Redmanol is also supplied in laminated sheets, rods, and tubes*

## We Help Manufacturers

**Our laboratories are constantly engaged in working out new applications for forward-looking manufacturers. It implies no obligation to submit your problem for solution. *Address* department 86.**

**Redmanol Chemical Products Co.**
636 W. 22nd St. Chicago, U. S. A.

### Redmanol Qualities

- Resistance to extreme heat.
- Exceptionally high dielectric strength.
- Great mechanical strength.
- Excellent acid resistance.
- Unusual accuracy of dimensions.
- Singular beauty of finish.

## Order Your Scientific and Technical Books *Now*

They are difficult to obtain and prices are constantly increasing. We will quote present price on any book of this nature and the price will hold unless the publisher should increase his price in the interim.

Write for our 96-page catalog—the most complete scientific and practical catalog now issued. In addition, our 1920-1921 list will be sent you as soon as ready, and the prices in this list will hold good in possibly 80 per cent of cases; but you will be notified of any change before filling order.

There will be no obligation in requesting catalog for we want you to know our Book Department. Write today. You'll find it valuable for suggesting books you need.

## Civil Engineering

*(Continued from page 326)*

who died in the war. The dimensions of this bridge are so great that it will be the largest single engineering work in steel ever built, or probably that ever will be built.

The suspension bridge, for structural reasons, is suitable for bridges of over 2,000 feet span, and for long-span bridges below 2,000 feet, the cantilever may be preferred. The two most notable examples of the cantilever are the two-track railway bridge over the Firth of Forth, whose two main spans measure 1,710 feet in the clear, and the Quebec Bridge across the St. Lawrence, with its main river span of 1,800 feet. Among the arch bridges, the longest single span is that built across the East River at Hell Gate, 1,017 feet between the abutments.

### Tunnels and Subways

Conspicuous in the review of the past seventy-five years of civil engineering are the vast works of tunneling which have been carried through as part of the work of providing urban and suburban communication. A first fruit of electrical facilities was the construction of the two main-line tunnels beneath the North River and the construction of electrified terminal stations in the heart of New York for the Pennsylvania and the New York Central Railroad systems. Then four tunnels known as the "Hudson Tubes" were built below the North River to give direct rapid transit from New Jersey to Manhattan. Another vast work was the construction of subways in Greater New York, which today have a total of over 600 miles of track in operation with a system of express trains running well above 40 miles an hour. The rapidity of sub-aqueous construction has been due to the use of the shield with pneumatic pressure.

### Foundation Work

The method of building deep foundations in loose and water-bearing material, contrary to the popular impression, has been long established. Smeaton, in 1778, sank the foundations for the bridge at Hexam, Northumberland, by the use of compressed air. As an alternative to that system we have the open cofferdam, a notable example of which was the construction by American engineers toward the close of the last century of the Hawkesbury Bridge in Australia. The closed caisson method has been invaluable in the construction of piers for bridges, and in the preparation of foundations for the modern skyscraper. Perhaps the most extensive use of the pneumatic caisson has occurred in this city, where the rock level is found at a depth of from a few feet to over 200 feet. With the introduction of the steel frame building the weight is concentrated at certain defined points over the area of the foundations and in building these, caissons are sunk to the solid rock and then filled with concrete to the appropriate level.

### Water Supply

Previous to 1845, the United States could boast of no city water supply of any magnitude, but about that period, the city of New York built a dam in the Croton watershed some thirty to forty miles from the city, and constructed also the old Croton aqueduct which brought the water from Croton Dam to service reservoirs in Central Park. Some fifty years later it was realized that the supply must be largely increased, and in the early 90's, a new dam and new aqueduct were built, and the new and old aqueducts together delivered about 385,000,000 gallons daily to the city. So great was the rate of increase in population of Greater New York that it became necessary to go much farther afield and bring in the mountain water of the Catskills. By the construction of the Olive Bridge Dam across the valley of the Esopus, the Ashokan reservoir with a capacity of 132 billion gallons was formed. This dam is 220 feet in height, and the water is led to New York City by an aqueduct from 14 to 17 feet in diameter which extends for a distance of 90 miles and in a deep tunnel is carried through the rock at a depth below the streets of Manhattan from 300 to 750 feet. Another notable water supply is that of the city of Los Angeles. The water is brought for a distance of 254 miles, partly in canal and partly in tunnel, and the daily supply to Los Angeles is 250,000,000 gallons.

Of all the great irrigation projects, the largest is that of the United States Government for reclaiming desert lands between the Mississippi and the Pacific Coast.

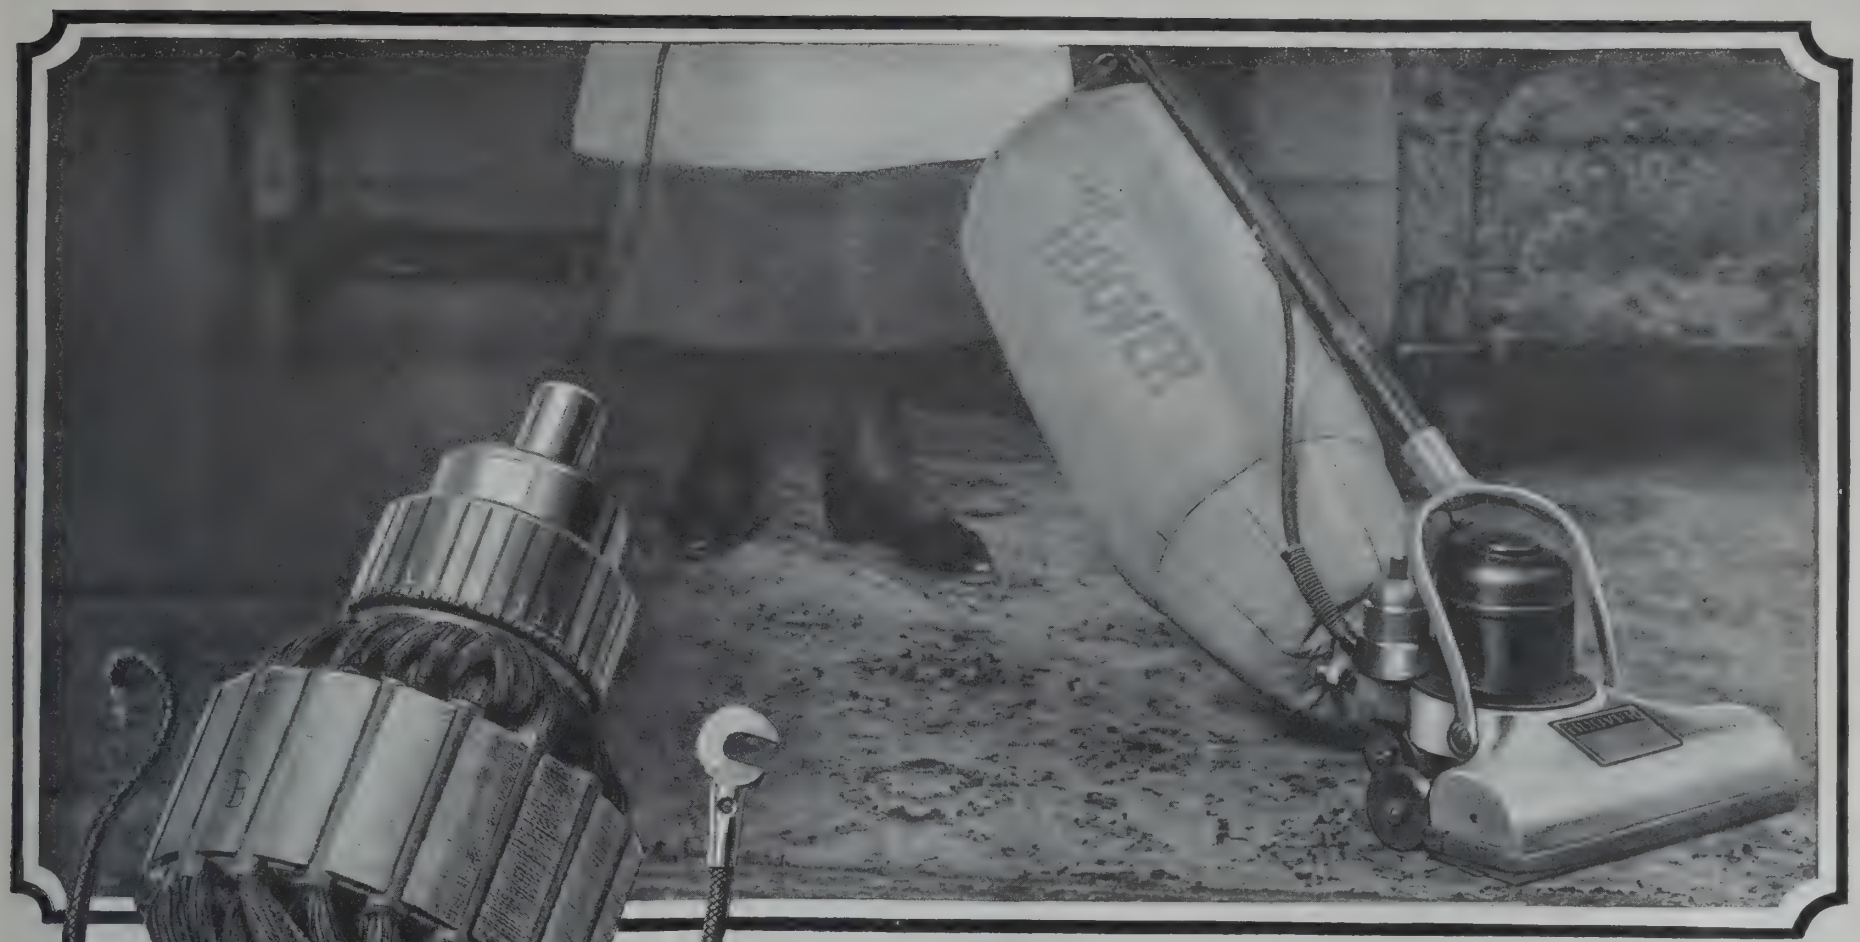
Among the many notable dams constructed for this work are the Roosevelt and the Shoshone dams, which are over 300 feet in height, and the Boise Canyon dam, 350 feet high. There are between 700 and 800 miles of canal, carrying from 300 to 800 cubic feet per second, and over 6,000 miles of smaller canals. Mention should be made here of another vast irrigation scheme made possible by the solid masonry of Aswan dam in Egypt, which extends for over a mile across the bed of the upper Nile River, and impounds 81,200,000 cubic feet of water.

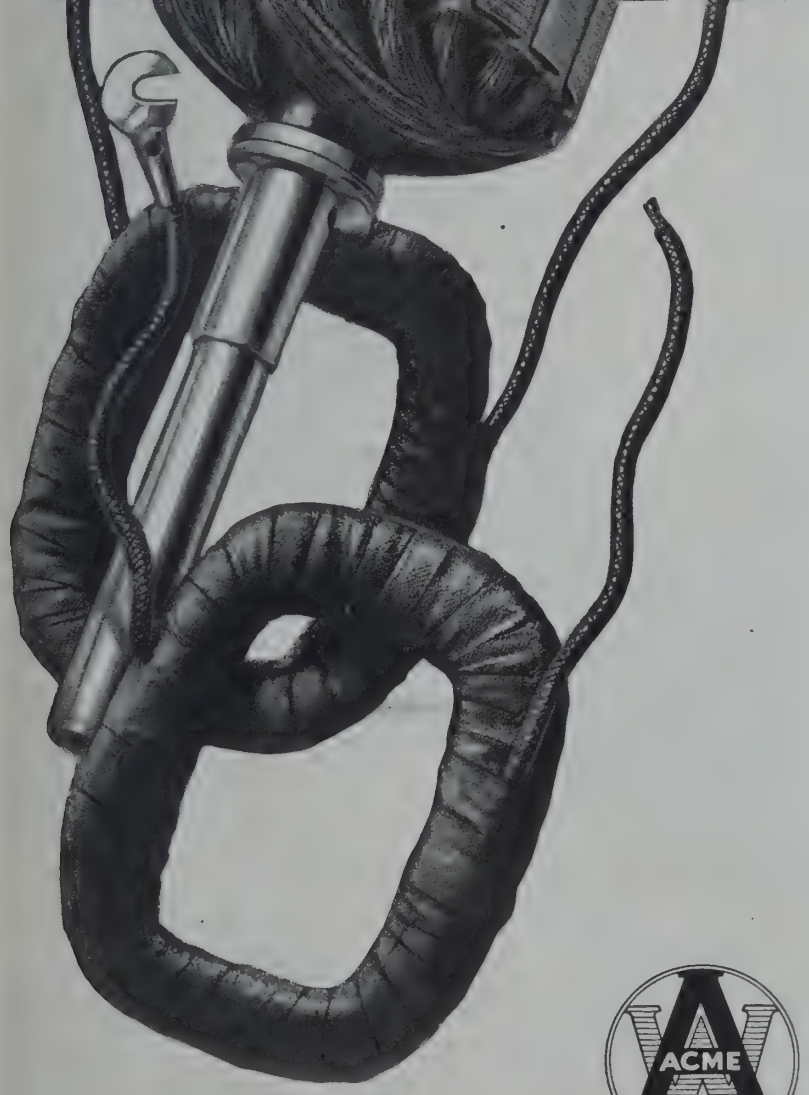
### Canal Construction

With the exception of road construction, the building of canals is the most ancient among the works of civil engineering, as witness the famous canals of Mesopotamia which rendered possible the flourishing civilization of the ancient races which dwelt in the valleys of the Tigris and the Euphrates. The greatest work of canal building in the United States during the past seventy-five years has been the continual enlargement and improvement of the Erie Canal connecting Lake Erie with the Hudson River by way of the Mohawk Valley. As opened in 1825, it had a maximum depth of only four feet; but improvements made between 1836 and 1862 involved the increasing of the depth to seven feet, and there has recently been completed a final reconstruction at a cost of over $150,000,000, which provides the canal with a minimum depth of twelve feet capable of taking barges of 1,000 tons.

Of the other notable canals built during the past seventy-five years are the Suez Canal connecting the Mediterranean with the Red Sea, which was completed by De Lesseps in 1869. Its original depth was 28 feet and subsequent work included the enlargement of the prism and the securing of a depth of 31 feet. The Kiel Canal between the mouth of the Elbe and the Baltic, a distance of sixty miles, was completed in 1895. There was completed by this country at the period of the opening of the great war the largest and most difficult work of canal construction in existence, namely the Panama Canal. It extends fifty miles from deep water to deep water, and it is remarkable for its great width and depth, the enormous amount of excavation involved and for the great difficulties encountered because of the climate and the unstable nature of the ground through which it was built. The problem of the turbulent Chagres River was solved by building a huge dam at Gatun and forming Gatun Lake with an area of 165 square miles. The dam is over 2,000 feet wide at its widest point. The depth of the canal is 45 feet. The locks have a width of 110 feet and a useable length of 1,000 feet.

The estimated cost of construction was greatly increased by the fact that what was supposed to be soft rock proved, on being cut and exposed to the water, to be a disintegrating material which flowed into the canal until it assumed a natural angle of repose of one to seven. The total cost is about $400,000,000.





# Inside Your Electric Cleaner

Nearly a Million new vacuum cleaners start work in American homes this year. They make home a better place to live in and take a big load off the womenfolk.

At least half of these electric parlor-maids have motors wound with Acme Magnet Wire—evidence of sure operation.

Where electricity comes into your life, as in vacuum cleaners, washing machines, doorbells, magnetos, self-starters, farm lighting outfits, for instance, Acme Magnet Wire and Acme Wire Coils give you the highest type of service.

Uniformly high quality is of vital importance to manufacturers of well-known electrical appliances—that's why so many of them use Acme Wire Products. "Acme Magnet Wire" means standard.

*Acme Wire—It goes in the space*

## Seventy-five Years' Growth of the Steam Railroad

(*Continued from page 330*)

railroad lines was equipped with block signals. In 1845, there was practically no block signalling in this country, and the Pennsylvania was the first road to make extensive use of the system, which it did in 1864. The Canadian Pacific adopted it in 1886, and thereafter it was gradually, but all too slowly applied to American railroads. Our great contribution to signalling was the introduction of the automatic signal, in which the train, by means of an electric circuit through the rails, operates its own signal and automatically safeguards itself. The first automatic signal was used in the universal track circuit installed on the Eastern railroad in Massachusetts, in 1871. Future development will be along the lines of what is known as the automatic stop, which consists in tying the signals in with the moving train so that if an engineer runs by a signal, the signal itself will automatically set the brakes and stop the train. A magnificent installation of this kind is that on the New York subway, where trains run at 40 miles under a headway of less than 1¾ minutes. So successful has this proved that something like a billion and a half passengers have been transported on the New York subways without the loss of a single life.

### Growth of the Steam Locomotive

The development of the locomotive has kept pace with, if indeed it has not been in advance of, the development of roadbed and general equipment. A typical locomotive of seventy-five years ago was a wood-burning engine weighing about eighteen tons and using the universal, Stephenson link motion. The earliest locomotives of this country were generally imported or were built along English lines; but very early the American locomotive began to develop its own peculiar characteristics. The rigid plate frame with inside cylinders, almost universally adopted in England where the roadbed was of more solid construction, was not found suitable to the more lightly constructed tracks of early American days. These tracks called for a special type of locomotive, having lateral and vertical flexibility. The lateral adjustment was obtained by means of the leading truck, and the vertical adjustment by means of equalizing levers. The weight is thus carried upon three points of support, one forward beneath the cylinders, and one on each side of the firebox. By this arrangement, the shock of any one wheel passing an obstruction is distributed and reduced before it reaches the main body of the engine. This combination made it possible to maintain high speeds over a track which would have ditched an English engine.

An engine of 1845 would have cylinders 15 by 20 inches, a weight of 20 tons, and drivers 4½ to 5 feet in diameter. Steam pressure was from 90 to 120 pounds. In 1848, the Baldwin Works built an express engine with cylinders 17¼ by 20 inches, and a pair of 6½ feet drivers; but she was considerably ahead of her time. That was a day of much experimentation. Single drivers of a diameter up to eight feet, were to be seen in service. A ten-wheel engine with six-coupled drivers was turned out by the Rogers Locomotive Company as far back as 1848. In the decade 1850-60, the coal-burning locomotive became common, and wood as fuel was gradually abandoned. About this time there came into use the wagon-top boiler, and the effect of anthracite coal was shown in the celebrated "camel backs" of the Ross Winans. The next deade, 1860-70, witnessed the introduction of the "Consolidation," the Bissel truck, and the swing-bolster truck. In 1870-90 there was a continual increase in the weight and power of locomotives, and they became classified into distinct types according to the work for which they were designed.

The compound engine was introduced into America in 1888, when the Pennsylvania Railroad purchased an English three-cylinder compound engine for trial. It proved to be highly economical, but it did not have sufficient power to haul the heavy passenger trains of the company's service. Compounding has been thoroughly tried out in this country with variable results. Today the tendency is toward the use of superheated steam in simple engines of large cylinder capacity. As showing the state of development of the passenger locomotive in the last decade of the previous century, we mention No. 999 of the New York Central system. This four-coupled express with 19 by 24-inch cylinders, 86½-inch drivers, 1930 square feet of heating surface and 190 pounds of steam pressure, hauled a 641-ton train from New York to Buffalo, a distance of 436.32 miles, at the rate of 64.22 miles an hour, exclusive of stops.

### The Era of High-Speed Travel

With the appearance of No. 999, there set in an era of high-speed passenger travel, which culminated in the first decade of the present century when the New York Central Railroad placed in service a train which made the trip from New York to Chicago in eighteen hours—a challenge which was promptly answered by the Pennsylvania Railroad. Since that time, in response to a demand for safety and for reasons of economy, the running time of these trains has been cut down, and it is not likely that any such speed schedules will be attempted in this country for many years to come, not at least until electrification has become general.

So far as locomotive design is concerned, the effort of the past two decades, and especially of the last ten years, has been to increase power so as to increase the capacity of the trains whether in freight or passenger service. The standard, heavy, express passenger locomotive of today has six coupled-drivers with a leading four-wheel truck and a pair of trailers beneath the cab; and the most powerful of these wonderful machines is capable of hauling a twelve to fourteen-car Pullman train weighing from 900 to 1,000 tons at the rate of sixty miles an hour on level tracks. An even greater increase in size and power has taken place in the freight locomotive, and we illustrate a well-known locomotive, the "Virginian," which was built by the American Locomotive Company for service on a stretch of fourteen miles of track which has a ruling grade of 2.07 per cent. This engine, the most powerful steam locomotive in existence has cylinders 30-inch diameter high pressure and 48-inch diameter low pressure by 32-inch stroke. The boiler has an internal diameter of 8 feet 7⅛ inches. The total heating surface, including superheater, is 10,725 square feet, and the tractive power when the engine is working the compound is 147,200 pounds; when working simple, it is 176,600 pounds.

### Introduction of Electric Traction

It was inevitable, in view of the success of the electric trolley, that electric traction should be applied to steam railroads. The first installation was for hauling trains through the belt line tunnel of the Baltimore & Ohio Railroad at Baltimore. This was followed by the very ambitious electrification of the terminal lines of the New York Central and the New York, New Haven and Hartford Railroads in New York City. This terminal zone, as it is called, extends 30 miles out on the main line of the New York Central to Croton, and some 75 miles to New Haven on the New Haven line. In the interval since that great work was decided upon, improvements in the art of electric traction have been such that it is now possible to utilize the direct-current system economically over continuous stretches of

(*Continued on page 354*)

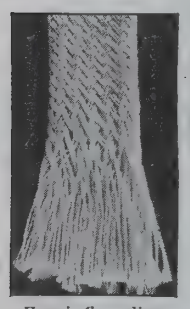
# Protecting the Insulation

THE real mechanical strength of any portable electric cord is in the *outside covering*. Once this covering wears through, the insulation is an easy prey to hard knocks, abrasion, oil, moisture, heat and even light—for light tends to make rubber brittle.

Duracord has a thick, heavy fabric cover *woven* like a piece of fire hose instead of the usual light braid. That's why it outwears ordinary cords 4 to 6 times. It has unusual strength where the wear comes—on the outside.

Duracord can be furnished in all sizes of portable electric cord and also in the larger sizes of single and duplex cable. Ask your electrical jobber about Duracord or let us send you samples of Duracord and ordinary cord for you to test and compare yourself.

*This is Duracord. Thick, heavy strands, woven like a piece of fire hose, not braided. Picture shows outside covering only with impregnating compound removed.*



*Here is the ordinary braided cable covering. Note the open and porous construction, easily cut, stretched or unraveled. Compare it with the illustration of Duracord above.*

## Seventy-five Years' Growth of the Steam Railroad

(*Continued from page 352*)

line, that could not have been economically operated ten to fifteen years before. The most famous installation is that made by the Chicago, Milwaukee and St. Paul Railroad for the operation of its mountain division; and for this purpose several exceedingly powerful passenger locomotives exceeding in their hauling power any previous locomotive, whether steam or electric, are in operation on that division. We illustrate one of these which has an over all length of about ninety feet. There are twelve 68-inch drivers, driven through gears by six electric motors, which develop a total of 4,200 horsepower for one hour and a normal starting drawbar pull of 100,000 pounds. The total weight of the locomotive is 275 tons, and it is capable of hauling the heaviest all-steel Pullman trains at a speed of 30 miles an hour on the steep mountain grades. It now seems to be only a question of time when we shall see a practically universal application of electric traction on the railroad systems of the United States. Based on data gathered by the Chicago, Milwaukee and St. Paul Railroad from its electrified mountain division, the fuel economy resulting from electric traction would represent a saving, annually in coal consumption of 122,500,000 tons of coal—that is to say, over two-thirds of the coal burned in the steam engines of our railroad system would have been saved during the year 1918, had the railways been completely electrified along the lines which today have been fully tried out and proved to be successful.

## Seventy-Five Years of Applied Electricity

(*Continued from page 333*)

his laboratory grounds were illuminated by seven hundred lamps, took place late in December, 1879, and attracted prominent visitors from all over the country.

Development during the years 1880 to 1889 was rapid and important. Lamp costs were brought down, as simplified methods of manufacture were introduced. The price of arc light carbons was gradually reduced from $240 per thousand to about $10 per thousand. The art of "pasting" carbon filaments to the lead wires was discovered; previously, the filaments had to be attached by expensive mechanical devices, such as tiny bolts, nuts, washers, sleeves and clamps.

By 1890 electric lighting was beginning to be common in every civilized country. In 1891 the cellulose or "squirt" process of making carbon filaments was commercially introduced. Two years later the cellulose filament generally supplanted the carbonized bamboo. In 1895 came the "chemical exhaust" for incandescent lamps, which improved their average quality, at the same time reducing their cost. Indeed, the cost was reduced from 32½ to 20 cents each by 1895.

In 1892 the substitution of molded bulbs for "free-blown" bulbs proved another step forward. Phelps, in 1898, invented the turn-down lamp. In 1898 Dr. Welsbach, of gas-mantle fame, produced his first osmium filament lamp, although metallic filaments came into general use many years later. The mercury arc lamp was originated by Arons in 1892, and later developed to a point of greater commercial practicality by Cooper Hewitt.

The invention of the enclosed arc lamp in a practical form was announced at an electrical convention in 1894, when L. B. Marks described the first enclosed arc lamp embodying the points that made it, for a period of ten years, the favorite unit for high candle-power lighting in America. In 1899 the Bremer flame arc was announced, and in the following year Bremer exhibited at the Paris Exposition a model having four impregnated carbons, so arranged that the light produced was thrown downwards. Other forms of luminous arcs followed, with various combinations of salts for producing various kinds of light.

The discovery of ductile tantalum came from a German laboratory in 1901, and the first experimentally successful tantalum lamp was constructed a year later, although several years more had to elapse before this form of lamp was ready for commercial exploitation.

In 1905 the "metallized" carbon lamp, in connection with which notable work was done by J. W. Howell, made its appearance and served as a sort of stepping-stone to the lamps of still higher efficiency that were about to make their appearance.

In 1907 came the pressed-filament tungsten lamp, for which we are indebted in great measure to two European inventors, Just and Hanaman. This lamp, in the hands of such men as Dr. W. D. Coolidge, Dr. A. Pacz, and a host of other experts, has gradually evolved into a strong, durable, cheap, drawn-wire lamp.

Within the past few years the gas-filled tungsten lamp has come to replace the vacuum lamp of the recent past. Indeed, at first these gas-filled lamps, generally using nitrogen, and in some instances argon, were available only in candlepowers running in the hundreds and even thousands. But during the past year or two the gas-filled lamp has been developed so that it is available in sizes as low as 50 watts, thus making it an all-round lamp.

### From Morse's Telegraph to Bell's Telephone

That historic telegraph message, "What hath God wrought!" sent in dot and dash over a telegraph line from the Capitol, at Washington, to Mount Claire Depot, in Baltimore, dates back to May 24th, 1844, one year before the initial appearance of the SCIENTIFIC AMERICAN. The message was indited by Miss Ellsworth, the daughter of the then Commissioner of Patents, and was intended to express the wonder of the achievement of the telegraph.

It was Samuel F. B. Morse who gave us the telegraph. As in the case of many other electrical machines and devices, we find many experimenters and investigators at work on the idea of communicating over wires by means of electric currents long before Morse's successful attempt; but the fact remains that Morse, like Marconi more than fifty years later, had to assemble numerous ideas together and work out the successful commercial telegraph. Hence Morse is the inventor of the telegraph.

Morse's original telegraph provided a pendulum carrying a pencil or marking device in constant contact wth a strip of paper that was drawn beneath the point by a gravity-operated movement. As long as no current came over the line, this arrangement would make a straight line upon the paper. The pendulum carried also an armature, and the electro-magnet was placed near the armature. A current passed through the electro-magnet would draw the pendulum to one side. On being released the pendulum would return, and in this way any amount of zigzag marks could be made on the paper as it traveled with the pencil constantly pressing upon it. Vail, an associate of Morse, made some changes in this device and substituted for the pendulum and marking pencil the familiar lever with pencil of a more recent type of Morse register, and substituted for the zigzag line the dot and dash system of telegraphy.

The telegraph is one device which has become simpler through perfection. As Morse conceived it, the telegraph was formidably complicated. For one thing, Morse wanted a recording device; he did not realize that men could be trained to read the signals by sound. Then he had trouble finding some suitable method of making the dot and dash signals at the sending end. For this purpose he used metallic type with indented faces so shaped as to open and close the circuit at

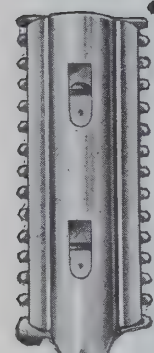
# Some Blade!

DURHAM-DUPLEX

*A Real Razor-made Safe*



You "hop to it" with a smile, and finish up the same way, when the Durham-Duplex is on the job. Good-bye to scraping and "pulling". Good-bye to face-burning and skin irritation.

The famous two-edged, detachable Durham-Duplex Blades are the longest, strongest, keenest blades on earth, oil-tempered, hollow-ground and scientifically stropped to an edge of surpassing sharpness—and guarded to prevent cutting.

It's the greatest blade ever. You'll say so yourself after a single shave with this real razor.

*Standard Set One Dollar*

Razor with attractive American ivory handle, safety guard and package of three Durham-Duplex Blades (6 shaving edges). All in handsome American ivory case.

## Seventy-Five Years of Applied Electricity

(*Continued from page 354*)

proper times and for proper periods. Each letter constituted a separate type, which was mounted on a portrule. When this was filled with type representing the message, it was drawn under the contact point. Then, as a simplification of this, two contact points close together were used, between which a wedge was thrust by hand so as to open and close the circuit. Again, a keyboard like a piano, with each key for one given character, was tried out and abandoned. But by 1844 Morse introduced the plain key very similar to that in general use today.

By 1855 the telegraph had become a commercial proposition of no mean proportions. A straggling web of lines under the control of thirty or forty rival companies, worked with different apparatus under different patents, covering the most populous area of the country.

Little had been done in the way of improvement. Indeed, the telegraph seemed about as efficient as could be wished for in view of the traffic requirements of those days. Operators here and there had begun to read signals by the sound of the marking lever. Morse was violently opposed to this practice, and insisted on the use of the tape. However, his collaborator, Vail, finally yielded to the operators' new method of reading signals, and by the simple suppression of parts, the well-known sounder came into being.

Some fifteen years later telegraph advanced still another step, namely, the duplex telegraph, enabling two messages to be transmitted at one time in either direction. The chief workers in this field were Gintl, Frischen, Siemens and Halske, Preece, Farmer, Nystrom, Maron, Winter, Stearns, and Muirhead.

Next came the quadruplex telegraph, with four messages sent simultaneously over one line. This seems to have been first proposed by Stark of Vienna in 1855, and subsequently worked at by Bosscha, Kramer, Mason, Schaak, and others. But the first to obtain satisfactory results was Edison, who invented his method in 1874.

From the land the telegraph passed to submarine cables, and many new problems arose which had first to be solved before commercial success became possible. The credit for having completely overcome these difficulties is mainly due to Dr. Muirhead of London. The experiments on short lengths in the English Channel and elsewhere fascinated American and British business men with the idea of a transatlantic cable, and it remained for Cyrus W. Field, who possessed unbounded persistence in his work, to lay the first transatlantic cable in 1866. With the aid of the "Great Eastern" a submarine cable was laid between Valencia, Ireland, and Trinity Bay, Newfoundland, in less than a month's time. The service was subsequently interrupted and repaired, but that is a matter of general history and of common knowledge.

The long cable brought out the fact that more sensitive instruments were required. Thomson, later Lord Kelvin, overcame the difficulty by inventing the mirror galvanoscopic receiver and later his siphon recorder. Other improvements followed.

Printing telegraphs, such as the stock quotation tickers, and high-speed telegraphs figure throughout the career of the telegraph, but space does not allow of touching upon these phases.

Like the telegraph, the telephone was suggested by various experimenters in an indefinite sort of a way, but it remained for the genius of Alexander Graham Bell to give the world the commercial telephone system. For instance, in 1861 Philip Reis of Friedrichsdorf disclosed in a lecture an instrument which he called a telephone, for the production at a distance of music and human speech. Perhaps Reis's telephone never talked, but it did transmit musical sounds. It was not until 1876 that Bell produced the first telephone which could transmit speech. Bell's patent has been called "the most valuable single patent ever issued." The early development of Bell's telephone was also due to Edison, Gray, Dolbear, Berliner, Blake, Hughes, and others. In 1877 Berliner invented the loose-contact transmitter and applied the induction coil between transmitter and receiver. These two inventions have been retained to this day.

Such men as Carty, Scribner, and Dean have brought the telephone to its present perfection. The one man who did most to create the switchboard is Charles E. Scribner. Prof. M. I. Pupin invented the loading coil in 1899, in order to obviate the bad effects of capacity on long-distance lines by increasing the self-induction. His invention made long-distance telephony practicable.

Within recent times we have the automatic telephone, which now threatens to supplant the usual manually-operated system because of the increasing difficulties in the way of maintaining a large personnel.

Another phase of communication is the telautograph, but so involved is the development of this method from the early efforts to the present perfected systems that nothing further can be said here. The same applies to the various systems of transmitting photographs and drawings over wires.

### Marconi's Contribution to Communication

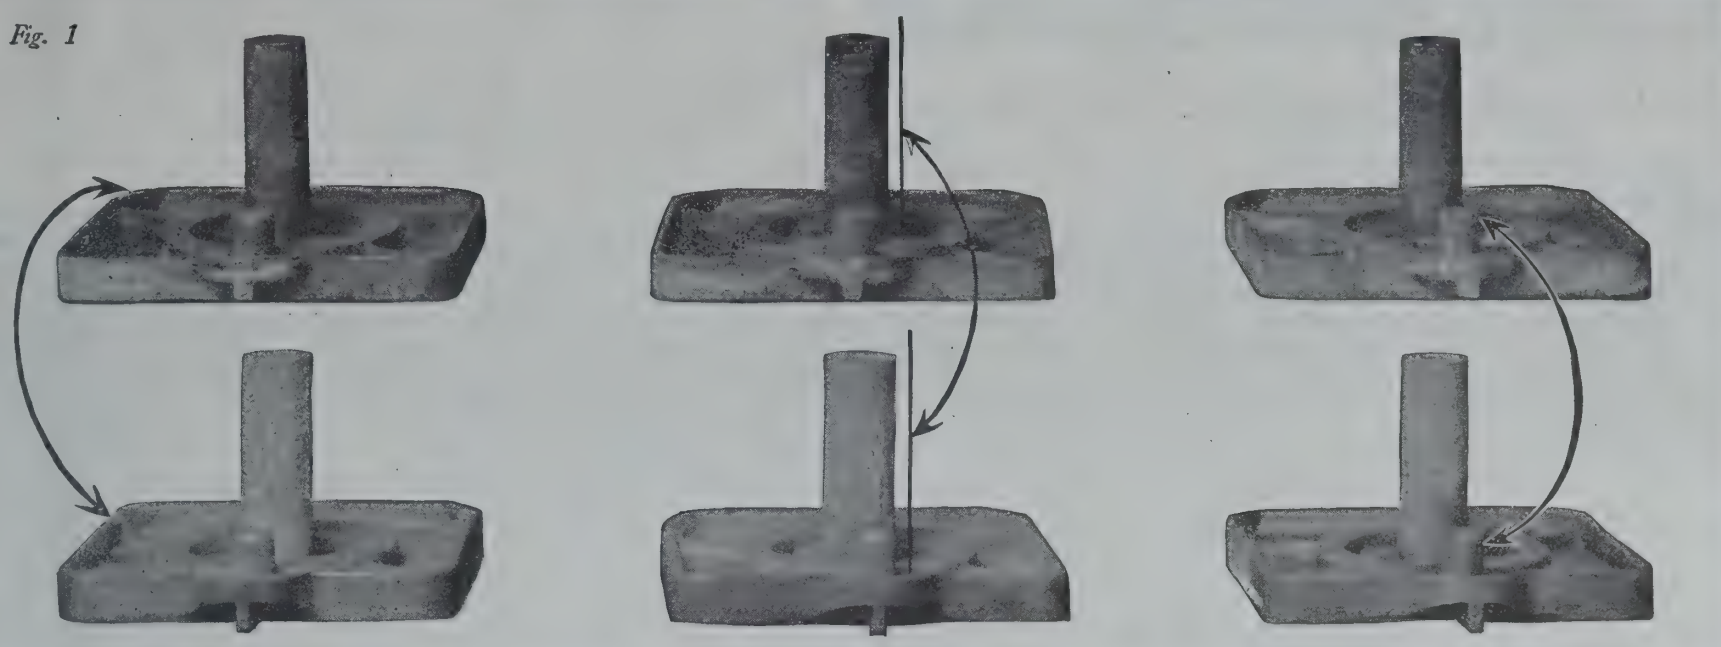
Again it is the old story of numerous attempts culminating in the work of one man capable of developing a commercially promising system; this time Marconi's story—and wireless. We must necessarily skip over the efforts of Hertz, Branly, Popoff, Lodge, and others and come right down to 1895 when Marconi, as a young man, was conducting experiments on his father's estate at Bologna, Italy. From a few hundred feet separating his transmitting and receiving equipments, Marconi soon increased the distance to over a mile. The apparatus was constantly being developed, and larger aerials and more power were being employed at the transmitting end. The distance covered rose to 100 miles, several hundred miles, and finally Marconi was ready for a transatlantic attempt. On December 12th, 1901, Marconi succeeded in transmitting repetitions of the letter "S" across the Atlantic from Poldhu, in Cornwall, to St. John's, Newfoundland.

Marconi was by no means alone in the development of wireless communication. In fact, many valuable contributions to the art came from many other inventors, and it is well to mention Fessenden, Fleming, Shoemaker, Lee de Forest, Braun, Poulsen, Ferrie and Wein. Wireless rapidly developed, and late in 1907 Marconi opened a restricted public radio service between Glace Bay, Nova Scotia, and Clifden, Ireland, thus going into direct commercial competition with the Canadian cables for the first time. Less than a year later the Glace Bay service was offered to all classes of telegraph traffic.

Since the war wireless has met with a remarkable development, due in large measure to the urgent necessity for all possible methods of communication. The transatlantic stations at Tuckerton, N. J., and Hanover, Germany, were put into communication as early as 1914, using the ingenious system of Goldschmidt. During the period of the war we find more and more wireless systems turning to the vacuum tube for receiving, amplifying, modulating and transmitting purposes. Indeed, this simple device—little more than an incandescent lamp with additional electrodes inserted in the vacuum—may be said to have solved practical wireless telegraphy and wireless telephony. Originally suggested by Edison's experiments, introduced in wireless communication by

(*Continued on page 358*)

*Fig. 1*



# Lower costs attained by elimination of unnecessary machining

NO detail of machine-shop work holds the eye of the inexperienced visitor more absorbingly than the spectacle of a machine as it gouges off deep bites of metal from a casting. Compute the cost of the machinist's time, lump in the proper overhead for the machine and floor-space, and then add the cost of waste metal and it becomes quickly apparent how expensive a form of entertainment this can be.

*Every unnecessary cut is pure waste.*

It represents a mistake in the selection of castings.

On this page are shown in photograph and diagram exact reproductions of castings taken from actual practice which illustrates the waste resulting from inferior castings.

The upper row in the photographic illustration above (see Fig. 1) shows a series of castings produced by machine moulding. Below is the same casting in series as made from hand-made moulds. Even in reduced reproduction the contrast between the non-uniform hand-made casting and the uniformly regular machine-made casting is easily apparent. (No effort was made to make a favorable selection of the machine-made castings.)

As the lower group of castings came to the machine shop for layout, each casting was a separate problem to the layout man. He was compelled to locate holes off center on bosses—and do many other undesirable things to make his principal cuts come uniform—or at all. Contrast this with the upper group of castings—"as like as peas in a pod"—the layout man's difficulties disappeared—repetition makes fast work easy.

Furthermore, in the case of the hand-made casting the shell of pad metal not only bulks greater but its thickness varies greatly. So great is this variation that frequently such castings, although they appear to the eye as O. K., are dangerously near being defective because there is no margin of metal between the surface of the rough casting and the specified dimension of the finished surface. When "hollows" penetrate even $\frac{1}{32}$" too deep, no choice then remains except to scrap the casting and charge to "Expense" the labor performed on it before the discovery.

The irregularity of the hand-made casting, when compared with the even, uniformly shallow depth of waste metal on the machine-moulded casting, makes clear at a glance the greater rapidity and uniformity possible in machining the latter.

Machine-moulding in the best machines can be accurately controlled within $\frac{1}{16}$ inch per inch of pattern draw. This degree of accuracy, backed by the fact that the machine-made mould is free from non-porous spots caused by hand-patching and slicking, insures the remarkable uniformity here pictured.

Based on this uniformity (and impossible without it), wholesale economies can be effected in machine-shop practice where large scale production is the goal. *First* comes the sweeping economy in layout time where one laying-out of a job serves as the only basis required for repetition day after day of the same cuts on castings which are themselves uniform. *Second* comes the saving in cutting time, due to reducing the shell of waste metal to a minimum. Compute the saving of only a single cut less across each face of a casting and then multiply it by the number of castings handled per day and you gain a partial

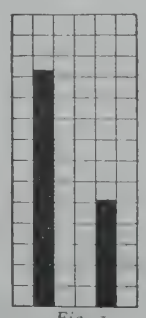


*Fig. 2*

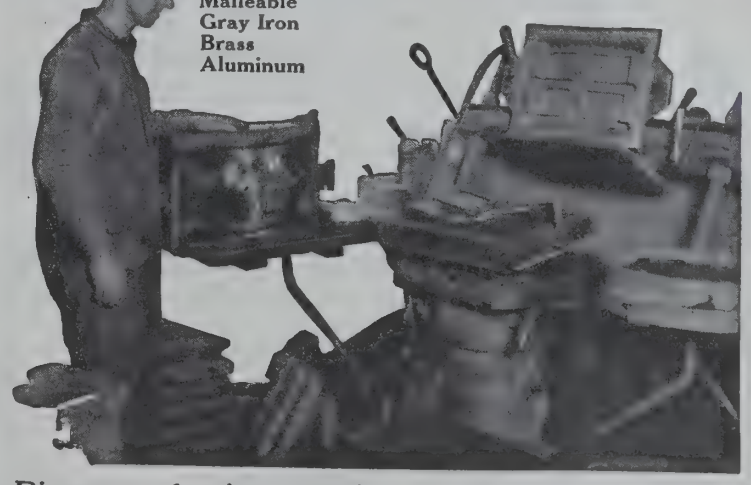
*Figure shows an average of comparative costs furnished by scores of machine shops before and after the adoption of machine-made castings.*

picture of the resulting yearly economy. The *third* economy results from the closely-held accuracy of the machine-made casting which virtually eliminates defective castings, and cancels the previous losses due to waste machining on defective castings—a decrease of 71% in defectives is the average result of the change to machine-made castings.

The sum of all these economies is graphically illustrated in Figure 2 which shows how the machining costs dropped in a large group of shops which adopted the machine-made casting.

BETTER CASTINGS

Steel
Malleable
Gray Iron
Brass
Aluminum



Bigger production would not justify machine-moulding if the castings were not unquestionably superior.

Osborn machine-molding turns out more castings in the same working-space, reduces or eliminates the loss in defective castings, reduces waste metal, reduces or eliminates chipping, scraping, stoning and filing, and assures satisfied customers.

In the Osborn line are hand or power-operated machines adapted to the requirements of any foundry. A letter will bring to your office an Osborn sales-engineer qualified to help you select the exact equipment for your particular needs. He will come back with actual facts and figures to substantiate every claim.

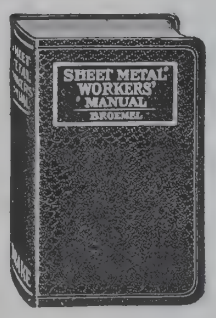
# DRAKE'S PRACTICAL MECHANICAL BOOKS

## Just the Information You Want



is readily found in these books. No matter what your line, in our big **FREE** CATALOG you will find a number of books giving exactly the information you want and applying directly on your own work. They will make your work easier and better, and **increase your pay.** Each book is written by a recognized authority in his field, and contains the very latest information and most approved ideas and methods.

Here are a few of the hundreds fully described in our catalog:

SHOP PRACTICE BOOKS

**Sheet Metal Workers Manual,** Leatherette. $2.00
**Oxy-Acetylene Welding and Cutting, and Electric and Thermit Welding,** Leatherette ..... 1.75
**Sound Welds by the Oxy-Acetylene Method,** Cloth ..... 2.00
**Slide Rule, and Logarithmic Tables,** Leatherette ..... 2.00
**Handbook for Millwrights,** Cloth..... 2.00
**Machine Shop Practice,** Cloth..... 2.00
**Mechanical Drawing and Machine Design,** Cloth ..... 2.00
**Pattern Making,** Leatherette..... 1.50

ELECTRICAL BOOKS

**Practical Applied Electricity,** Leatherette. $2.50
**Alternating Current,** Leatherette..... 1.75
**Electric Motor Control Systems,** Leatherette 1.75
**Electrical Tables and Data,** Leatherette.. 1.75
**Modern Electrical Construction,** Leatherette 1.75
**Electricians' Operating and Testing Manual,** Leatherette ..... 1.75
**Electric Motors, D. C. & A. C.,** Leatherette. 1.75
**Electrical Measurements and Meter Testing,** Leatherette ..... 1.75
**Wireless Telegraph and Telephone Handbook,** Cloth ..... 1.25

AUTO BOOKS

**Automobile Ignition,** Leatherette..... $2.00
**Automobile Starting and Lighting,** Leatherette ..... 1.75
**Starting and Lighting Troubles, Remedies and Repairs,** Leatherette ..... 3.00
**Automobile Battery, Care and Repair,** Leatherette ..... 2.00

FINGER PRINT BOOK

**Finger Prints Simplified,** Cloth..... 2.00

ENGINEERING BOOKS

**Swingle's Handbook for Steam Engineers and Electricians** ..... 3.50
**Examination Questions and Answers for Marine and Stationary Engineers.** .... 2.00
**Swingle's Catechism of Steam, Gas and Electrical Engineering** ..... 1.50

Any books sent prepaid upon receipt of price. Order from this ad. Money back if not satisfied.

These are but a few of the many we publish. Be sure to get our big catalog, sent free.

## Seventy-Five Years of Applied Electricity

(*Continued from page 356*)

Fleming, and developed to a high state of perfection by Dr. Lee de Forest, the vacuum tube constitutes the greatest step forward in the art since Marconi's first experiments. The vacuum tube, in its multitudinous sizes and designs, permits doing things hitherto deemed impossible.

The wireless telephone is a natural growth of the wireless telegraph. At first the electric arc was employed as the generator of high-frequency currents for radio-telephone purposes; but with the development of the vacuum tube the arc has lost its place in radio telephony except when it is a question of tremendous power. Even then, there are high frequency alternators, such as the marvellous machine of Alexanderson, which lend themselves to radio telephony. Such names as Poulsen, Fessenden, Colin, Jeance, de Forest, Arco and Majorana figure in the development of the radio telephone.

Nineteen hundred and twenty—and we have attained what appears to be perfection in wireless communication. We have numerous stations capable of transmitting and receiving signals over thousands of miles. The atmospheric disturbances have been largely ameliorated, and even now there are certain antistatic systems which promise to render wireless systems as immune from such disturbances as the underground telephone cable. It is a great step, to be sure, from Marconi's crude set of 1895 to the 12,500-mile Lafayette radio station at Bordeaux, France, constructed by the United States Navy during the war so that we might never be out of touch with our men "over there."

## The Rise of the Automobile

(*Continued from page 335*)

still run by single-cylindered engines; the Haynes-Apperson, Winton, Stearns, Oldsmobile, Stevens-Duryea, Arrow and Peerless employed two cylinders; the Gasmobile boasted one of the earliest fours. For the next year the Locomobile came on the market in two- and four-cylinder models and the Franklin appeared as a four, while the Peerless added a four to its line; current opinion would doubtless have named two cylinders as standard practice for the ordinary car, and four as desirable in the big fellows. By 1905 the four-cylinder standard was well established. In 1907 the first six-cylinder model appeared in England, the work of Napier, and the precedent was quickly followed, until by, say, 1910, it might have been said that the two-cylinder car of 1902 had become a four, and the four a six. At the same time Hewitt produced an eight, but this precedent was ignored for nearly a decade; the earliest of the existing eights appears to be the Cadillac, of 1914. The tendency toward sixes, and later eights, continued; and finally, in 1915, the Packard, almost the last car to give up the single cylinder, was the first to set the mark at twelve.

A change of importance that ought to be mentioned is that from chain drive, universal in the early models, to the propeller shaft with bevel gears. If a date were to be set at which this became first effective, it would be somewhere in the vicinity of 1905.

The early designers surrounded the single cylinder with a water jacket, but made no definite provision for water economy. Perhaps they did not expect their cars to run far enough, on one stretch, to require fresh water. But by 1900 the cruising radius had gone up, and radiators recognizable as such made their appearance, though as late as 1902 they were universally low with sloping fronts. The higher, vertically up-standing type appeared in 1904-05, and swept the field clean within two years at the most. Circulation was by pump, until the Renault designers incorporated the thermo-siphon, which spread to a few other models after 1907. But it must be emphasized that air-cooling is not a recent development; the Franklin, which would be the Wilkinson if named after its creator, dates back continuously to 1902-03, and the Knox and Marmon, among others, were air-cooled for a time.

The dividing line between horseless carriage and automobile may perhaps be drawn from the point where the motor was transferred to the front and the conservative upright steering post with horizontal rod replaced by the more sporty wheel. Among the names that lived, the Knox, Duryea, Haynes, Oldsmobile, Stearns and Pierce were all handled through rods in 1902; the vogue of the wheel appears to have become definitely established not earlier than 1904. And Levassor's example in putting the engine where it belongs was still defied in 1902 by the Stearns, Pierce, Packard, Oldsmobile and others, but had become universal two years later. So perhaps we might say that the period before 1900 was that of the horseless carriage, and that after four years of transition we come to the automobile.

### A Problem in Prosperity

It seems amusing to us, today, to turn back to 1910-12 and read that the vast increase in the use of the automobile had caused such a demand for gasoline that the quality had gone down to a point that constituted a problem. We will understand this better if we realize that the cars of 1900 and 1905, burning the high-grade gasoline then on the market, were expected to start, under all conditions and without priming, on a half or even a quarter turn of the crank. When the fuel became of such sort that this was not feasible, there was a universal consensus that some sort of starting motor would have to be devised. A great many sorts were put forward, but those that worked pneumatically or through springs or by introducing a preliminary charge of acetylene or some other violent explosive and touching it off with the spark went overboard when it was shown clearly that a wet battery could be built that would not be damaged by such roughing as it would get from riding in a car, and that a generator could be installed that would keep it charged to the necessary voltage for starting. The development of the electric starter began in 1910, and by 1913 was complete, all the better cars being by that time so equipped. But if a battery must be carried for this purpose, economy demands that it be used also for lighting and ignition, relieving the car of weight and installation expense represented by oil lamps and magneto. So we find at this time the very general reversion to battery ignition, referred to above. The magneto, however, has not submitted tamely to this. Admitting that at the slow engine-speeds of cranking, whether manually or by motor, the battery gives a better spark than the magneto, the advocates of the latter point out that its spark increases in intensity with engine speed and that it ought therefore to be better after the car gets under way. Opinion here is still in a point of flux; and it is difficult to say whether the present vogue of dual ignition represents really an effort to get the best of both systems, or merely a desire to sidestep the question of choosing between them.

### From Sport to Utility

In the beginning automobile design and operation was a recreation, a means of riding a hobby and at the same time gratifying the mechanical instinct that impels men to play with motor boats and wireless and such things. A man built a horseless carriage and drove it about the roads of his home town, not so much from the desire to achieve transportation

(*Continued on page 360*)

# UNDARK Radium Luminous Material

## "I want that on mine"

It is a great convenience to have clocks with UNDARK dials; you can read them in even a pitch-dark room.

Makers of mantel, alarm, and travelers' clocks are using UNDARK to illuminate the dials.

UNDARK watch dials are included in almost every desirable make, because the makers realize that watches should give a 24-hour sight service.

### UNDARK doesn't get dark in the dark

This radium luminous material contains real radium and keeps its glow for years.

Its uses include service on electric buttons, pull-chain pendants, locators, locks, door-knobs, and house numbers. It is put on pistol sights for straight aiming in the dark. UNDARK is used on hundreds of novelties.

We are miners and refiners of radium-bearing ore, the pioneer manufacturers of radium luminous material in this country and the largest in the world.

If you are interested in seeing how UNDARK can be applied, we will send you a TRY-OUT set for $3.00. In writing, state class of work for which you want to use it. We can also give you the names of manufacturers who use UNDARK on the particular articles in which you are interested.

**UNDARK is used on numerous articles, of which the following are the most important:**

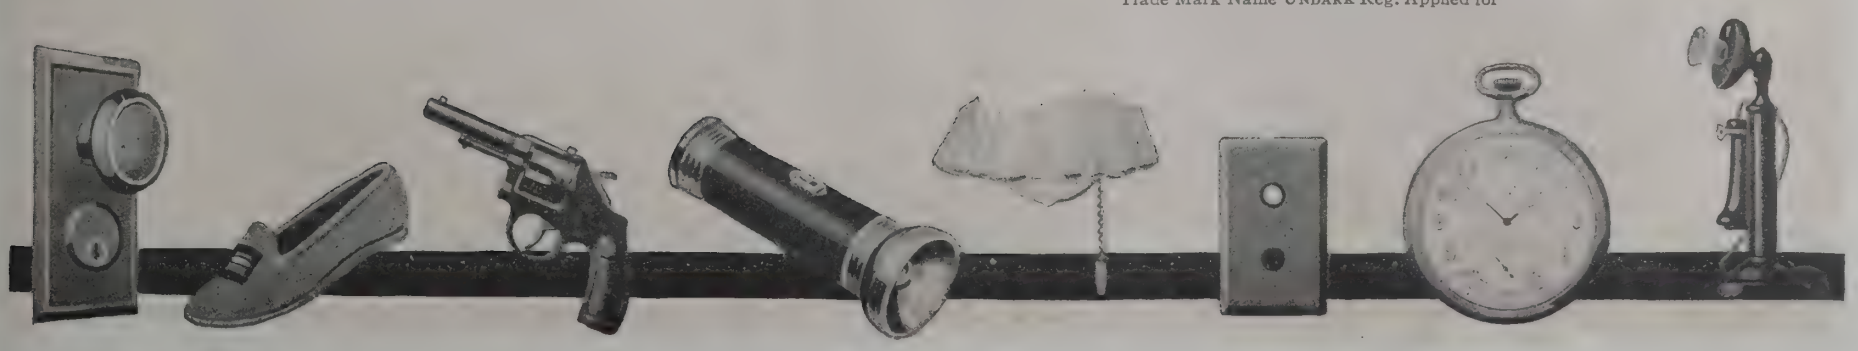
| | |
|---|---|
| Watches | Gasoline Gauges |
| Clocks | Speedometers |
| Flashlights | Steam and Pressure Gauges |
| Pull-Chain Pendants | Revolver Sights |
| Push-Button Switches | Telephone Mouthpiece |
| Flip Switches | Fire Extinguishers |
| Door Bells | Mine Signs |
| House Numbers | Women's Felt Slippers |
| Hospital Call Bells | Fish Bait |
| Ship's Compasses | Theatre Seat Numbers |
| Locks | Convention Buttons |
| Safe Combinations | Poison Indicators |

**Names of the makers of these furnished upon request**

*UNDARK can be successfully applied by manufacturers in their own plants. It is a simple process. We will instruct operators and organize the work for you. Write for details.*

**Radium Luminous Material Corporation**
**58 Pine Street, New York City**
**Factories: Orange, N. J. Mines: Colorado and Utah**

Trade Mark Name UNDARK Reg. Applied for



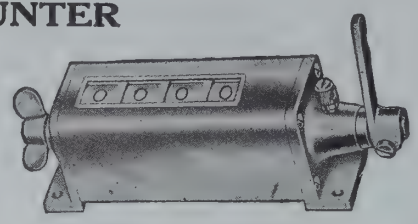
# Saving Profits from Price Drops

There's the making of a reduced labor-cost in every machine running at half-way productiveness. Pick up the idle capacity by *checking-up* the operator's output; see that it squares up with figures denoting *reasonable industry,* as indicated by a

Veeder
COUNTER

The No. 14 **Ratchet Counter** above registers one for each throw of the lever, recording number of operations of the smaller stamping presses, etc. Supplied with outside stops which regulate the throw of the lever, and having return spring action which automatically returns the lever into position for the next count. The lever is adjustable, allowing the counter to be used at any angle. Price, $2.25

(*Cut nearly full-size.*)



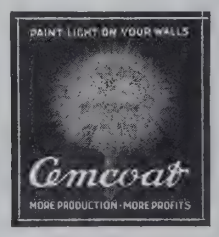
This large **Set-Back Rotary Ratchet Counter** records the output of punch presses, metal-stamping machines and others where a reciprocating movement indicates an operation. Registers one for each throw of the lever, and sets back to zero from any figure by turning knob once round. Provided with from four to ten figure-wheels, as required. Price with four figures, as illustrated, $11.50. (List.) Equipped with lock and keys to prevent tampering with the record, $2.00 extra.

(*Cut less than half size.*)

*Don't run a machine at less than capacity for lack of a Veeder Counter; there's a model for every counting-job. Look over the line in the Veeder booklet; a word will bring you a copy.*

The Veeder Mfg. Co., 18 Sargeant St. Hartford, Conn.

SONNEBORN PRODUCTS



THE best lighted factory has a big competitive advantage. It can produce more at lower cost because its workmen work harder and faster, with fewer wasteful mistakes.

Paint more light on your factory walls. Cement them now and get more light with fewer lights.

Cemcoat

is the glossy mirror-like wall coating which multiplies natural and artificial light by reflecting it from every angle.

As the cost of applying paint is high it is most economical to use the longest lived mill white, Cemcoat.

Cemcoat is not only more durable than common paints but it holds its gloss and whiteness much longer.

SONNEBORN PRODUCTS
LAPIDOLITH
makes old or new concrete floors dust-free and wearproof by chemical action. Just flush it on.
LIGNOPHOL FOR WOODEN FLOORS
the modern wood preservative, gives new life to old or new wooden floors.

Furnished in Flat or Egg-shell, White and colors.

Write now for the experience of others who have more light and more production through the Cemcoat system.

## The Rise of the Automobile

(*Continued from page 358*)

as to satisfy the inventive impulse in a wide-open field. When the experience of the pioneers had crystallized to a point which gave the driver of such a vehicle a sporting chance of getting it home again the same day, a market appeared for its sale to men who were willing to drive it but unable or unwilling to build it. On this basis the new industry had its beginnings; men like Haynes and Duryea and Olds in America, Panhard and Levassor in France, found that they could sell their machines to others, and immediately made it their business to do so.

The end of this experimental period might be set somewhere around 1899. It was here that the name "automobile" began to drift in from France, while self-propelled vehicles were seen in our streets with sufficient frequency to make it worth the small boy's while to coin the standard jibe, "Get a horse!" with which to greet them. The decade from 1898 to 1908, perhaps a bit shortened at each end, might fairly be called that of the automobile's adolescence—the period during which, like adolescent humans, it was always on the *qui vive* to show what it could do. In real, practical utility there was little advance over the preceding five years; but the automobile was so much faster and so much more reliable that real racing, on road and on track, was now profitable, and became characteristic of the epoch.

With due allowance for the extremes to which it was carried, this was a necessary stage in automotive developments, and one which led swiftly and surely to better machines. For if the race is to the fastest, it is equally to the contestant who is able to keep going. And when its racing performance had sufficiently demonstrated the automobile's ability to keep going, there were plenty of hard-headed gentlemen of finance to inquire whether there was not something useful that could be done with it. In answering this question in the affirmative the automobile industry passed into its third and present stage, that of wide commercial development as a recognized utility.

With the quest of utility, however, the designer must fact a brand new problem—that of building cars of diverse types for diverse special purposes. One angle of this problem is seen in the divergence of passenger cars. This multiplicity of types is a feature of the present-day automobile whose relative newness often escapes us.

Another thing that happens when the designer begins to consider the purpose for which his product will be used is the great divide between car and truck. So far as any published figures show, the first machines built in the United States for strictly and admittedly commercial use and under a separate classification were of date 1904. The beginning was small enough, only 411 trucks for the year; but these were really trucks, with frames and axles built for heavy loads and with power plant and transmission designed for the peculiar demands of hauling merchandise.

### Truck and Tractor

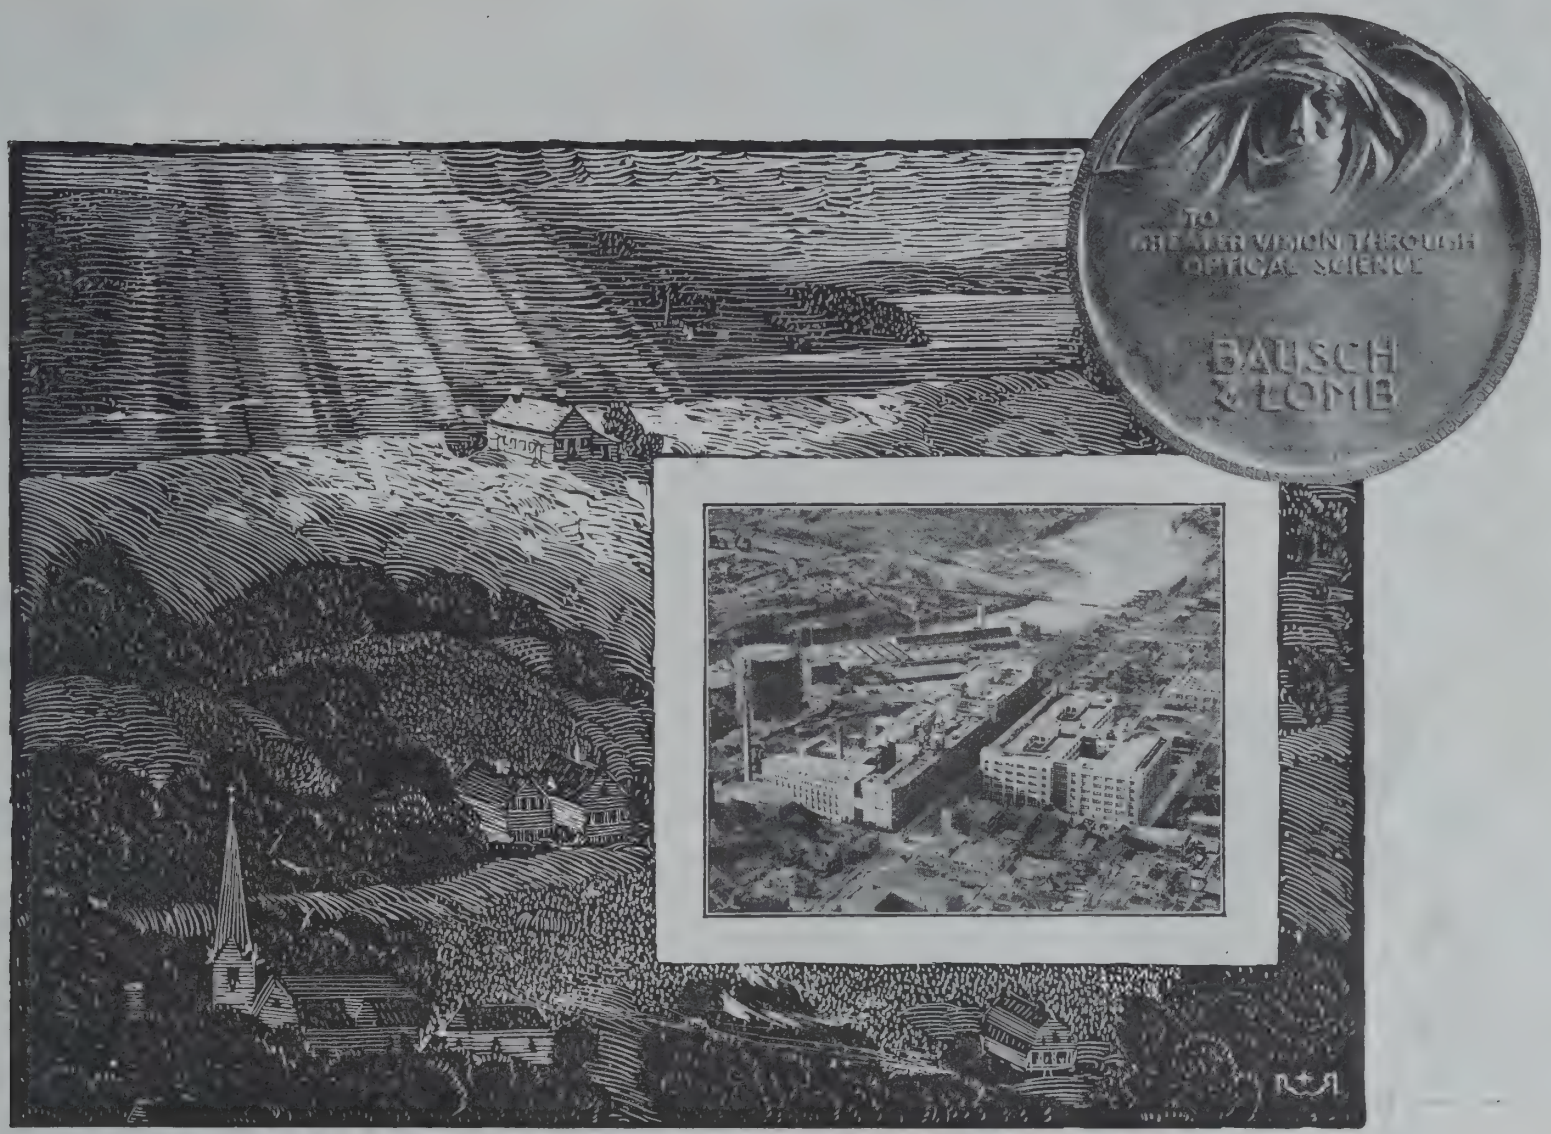
The trend of truck development is too technical to follow in detail, but we may note the major points of departure from passenger cars. The tendency in trucks is of course always toward greater load capacities, and toward ruggedness rather than refinement of detail. A significant divergence from passenger car history is shown in the development of the engine, which has met the additional demands from year to year by an increase in the size rather than in the number of the cylinders. The final drive has remained a much more open question than in the case of passenger cars. There are at least four fundamentally distinct systems still in vogue, including the chain drive so long ago discarded from passenger cars; and in addition the four-wheel-drive principle invented in the earliest days of truck manufacture continues in use by some makers, and offers another distinctive truck feature.

A little brother—sometimes, indeed, a pretty big brother—of the truck must be mentioned in the tractor. This is inherently a truck, with some means provided for taking better hold of the ground than is afforded by the ordinary tired wheels, so that it shall pull effectively when hitched to heavy agricultural machinery in the field. Wide rollers in place of ordinary wheels were the obvious first step; later these were provided with projecting plates and spikes of various sorts; finally the war, with its reinvention of the crawling, track-laying principle, gave the tractor manufacturer his biggest grip on the situation. Trucks of course have been used for hauling agricultural machinery since they first came out, just as there has always been more or less commercial use of passenger cars for light delivery work; but the tractor as an independent member of the automotive family might be dated back to 1912, with due recognition of earlier efforts.

### The Automobile in 1920

The present survey may well be concluded with a word about the position held today in the world's economy by the automotive industries. It is in a way hardly necessary to dilate upon this, yet one or two concrete statements may help to a true realization of the vital importance of the automobile to our way of doing things. For one thing, we are told that while all the railroads of the United States in the course of a year yield about 45 billion passenger-miles, the automobiles of the entire nation are responsible for 70 billion of these units of transportation. Again, with the 3,700 passenger cars manufactured in 1899, the first year for which records exist, and with the 411 trucks of 1904, we may compare the present normal production of some two million passenger cars and three hundred thousand, plus, trucks. Finally, we have the fact that there are something like seven million automotive vehicles of all sorts in operation in this country today. Figures are given for the United States for the very simple reason that, alike in manufacture and use, this is the land of the automobile.

Under the head of general remarks about the rôle of the automobile in twentieth century economy the difficulty is wholly that of finding a brief statement that shall do the subject justice. In every single thing that we do today the automobile or the truck or the tractor occupies a position of importance. Perhaps the most illuminating statement that could be made would have to do with the manner in which all distances up to fifty, seventy-five, or even a hundred miles are made to vanish into nothing by the magic influence of the motor. The isolation of farm life is a thing of the past, for the farmer cannot possibly be more than an hour from a town that gives him access to high-class schools and stores and amusements. City congestion, serious as it is, would be vastly worse were it not for the manner in which the automobile extends the suburbs and the area of food supply far beyond the remotest possibilities of twenty years ago. Trucks carry freight from New York to Philadelphia in less time than it would take to get it to the freight yards and loaded on a train. In a word, the automobile—taking this term to include all gasoline-driven vehicles—is with little question the greatest ameliorating influence in modern life. And all this is an invention, not of the past 75 years, even though for its ultimate beginnings we have to go back almost to that time; but, as regards the time which has elapsed from the first really promising attack upon the major problems involved, a development of thirty-five years at the most.



# Grown Great Through Service to Mankind

FROM a tiny room to the titan plant pictured above, whose floor space spreads over twenty-five acres and whose place is recognized as greatest among the world's manufacturers of lenses and optical instruments—that is a far, far span. It is the story of the house of Bausch & Lomb—the story of great growth through great service.

Nearly seventy years ago John J. Bausch dedicated himself to the task of making glasses "that human eyes might see better and farther." Obscure, maimed, in debt, he struggled through long, unrewarded years, upborne alone by his undeviating resolution to succeed through work done worthily.

Today, through the house he founded, his service to his fellow man has infinitely multiplied. Today the activities of Bausch & Lomb cover the world-wide field of optics.

Through their Microscopical Apparatus, Science discovers atomic, destructive myriads, and devises means for man's protection; through their Ophthalmic (eye) Lenses is done mankind's service in preserving man's most precious sense; through their photographic and photomicrographic lenses world and atom, nature and man are unerringly recorded; through their projection lenses and apparatus the wonders of the earth are vividly portrayed on countless screens, while their giant light reflectors flash wide assurance across the deep.

It is with a frank humility that Bausch & Lomb speak of these achievements in the field of optics. We recognize that such growth has been permitted us only by reason of that spirit of service through faithful, worthy work and the helpful co-operation of our scientific friends in the professions and trades which has tirelessly continued since John J. Bausch toiled in his little shop. That spirit is today our most greatly prized possession; and it is a spirit which we pledge ourselves to maintain in that wide field of optics where our leadership has been won.

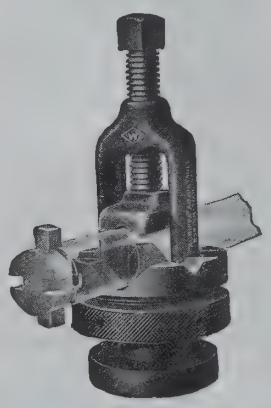
11 Mercer St. New York



# Why Use Makeshifts?

WHY waste time and energy with makeshift devices for boring operations when Williams' "Agrippa" Adjustable Boring-Tool Posts offer convenience and efficiency developed to the nth power.

Each Post accommodates a wide range of Bars, the height of which is readily adjusted; a turn of the Knurled Ring raises or lowers the base on which they rest. The whole device is instantly and rigidly locked by tightening the Set Screw.

Four sizes for ½" to 2¼" diameter Bars—furnished with or without Bars.

## The Mastery of the Skies

*(Continued from page 339)*

The SCIENTIFIC AMERICAN during its seventy-five years of existence has chronicled the numerous and divers attempts at dirigible construction and travel. Thus in 1852 it chronicled the attempt of the Frenchman Giffard, who constructed a spindle-shaped balloon 143 feet long by 39 feet in diameter, and driven by a three-horse-power steam engine actuating a 11-foot screw. This dirigible voyaged from Paris at a sustained speed of six miles per hour through the air and with good control. In 1872 the German, Haenlein, with a cucumber-shaped coal gas balloon 164 feet long and 30 feet in diameter, driven by a gas engine taking fuel from the envelope, and actuating a single screw, attained a speed of ten miles per hour. In 1884 Renard and Krebs, in a torpedo-shaped dirigible 165 feet long and 27.5 feet in major diameter, driven by an electric battery motor, actuating a screw propeller, made the first return voyage against a moderate wind. The vessel showed excellent control, attained an average speed of 14.5 miles an hour, and was of model workmanship; but for lack of power it was practically abandoned till the advent of the automobile engine.

In 1898 Santos-Dumont, emulating the German Wölfert, who in 1880 first attempted to drive a dirigible with a benzine motor, sailed aloft in a spindle-shaped balloon 82 feet long by 11 feet in diameter, driven by a motorcycle engine of 3½ horse-power, carried in a car suspended beneath the envelope. Finding this vessel manageable and swift enough to make his clothes flutter, and amply rigid when its ballonet was properly inflated, he in subsequent years built fifteen more dirigibles of various designs.

Came 1900 and Count Zeppelin's début as an airship constructor. Emulating the Austrian, Schwartz, who in 1879 first tentatively drove a rigid metal balloon with a petrol motor, Zeppelin launched the first of his huge rigid dirigibles. Its hull, which was framed of aluminum and contained seventeen compartments holding buoyant hydrogen gas bags, measured 416 feet long, 38 feet across, cubed 400,000 cubic feet, weighed nine tons, and had a displacement of ten tons.

Rapid progress has been made during the past decade in dirigible construction. The Zeppelin craft have been growing steadily larger in size and power and carrying capacity. The latest Zeppelins have a length of close on to 700 feet and a cubic capacity of well over two million cubic feet of gas. Seven engines and six propellers drive the Zeppelins of today. The British rigid dirigibles are closely patterned after the German Zeppelins, and the British R-34 was to all intents and purposes a Zeppelin.

### How Man Grew His Wings

The fundamental theory of the airplane was set forth by an Englishman, Sir George Cayley, as early as 1809, and actually furnished the basis upon which the modern flying machine was subsequently built. In 1846 another Englishman, Stringfellow, gave a practical proof of this theory by building a small airplane model driven by a steam engine, which made several successful flights under perfect balance; this machine was, in conformity with Cayley's theory, a monoplane. In 1866 F. S. Wenham, also of England, invented the multiple-surfaced airplane and it was again Stringfellow who vindicated the claims of the new principle by a successful free flight of a triplane model. Further important contributions to the dynamics of the airplane were made by A. Penaud, H. Phillips, Sir Hiram Maxim, and S. P. Langley. The latter, an American and secretary of the Smithsonian Institution, built in 1903 a man-lifting monoplane which, but for its defective launching device, would have flown.

It is pretty generally admitted that the first airplane to have actually left the

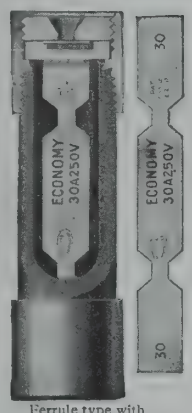
## You Buy the Highest Type of Electrical Protection

in any circuit when you install Economy Renewable Fuses—made in both ferrule and knife blade types in all capacities.



Ferrule type with Economy "Drop-Out" Renewal link

Accurate rating, practical, safe fuse construction and a dependability which has been proved for years in thousands of industries, large and small, make Economy Fuses first choice where efficiency is the first consideration.

# ECONOMY *renewable* FUSES

## And You Cut Fuse Maintenance Cost 80%

compared with the maintenance cost of any "one time" fuse equipment.

Knife-blade type with Economy "Drop-Out" Renewal link

Only the "Drop Out" Renewal Link is destroyed when the fuse blows.

Both ferrule and knife-blade types are easily and quickly restored without expensive delay in service.

**Economy was the first line using inexpensive bare renewal links for restoring blown fuses to their original efficiency to be APPROVED IN ALL CAPACITIES by the Underwriters' Laboratories.**

***Sold by all leading electrical jobbers and dealers***

**Economy Fuse & Mfg. Co.**
**Chicago, U. S. A.**

Economy Fuses are also made in Canada at Montreal.

ground, carrying a man, was the bat-shaped machine fitted with a 20-horse-power steam engine with which C. Ader, of France, made several short flights from 1890 to 1896. The balance of this machine, however, was poor, and it was only after the German, O. Lilienthal, had discovered by prolonged gliding experiments the means of controlling the balance of flying machines that progress became practical. Lilienthal's gliding experiments were repeated and perfected in this country, under the guidance of O. Chanute, by the Wright brothers of Dayton, Ohio. These brothers gave the airplane its one missing link, the warping mechanism for insuring transverse equilibrium; and having thus brought the dynamic flier under three-dimensional control, the Wright brothers fitted their glider with a gasoline engine driving twin propellers and succeeded in making their first power flights on December 17th, 1903, on the beach at Kitty Hawk, N. C.

The first float seaplane that left the water under its own power and returned thereto was built by Henri Fabre, of France, the trials taking place on March 28th, 1910, near Marseilles. Thence the development of the seaplane was chiefly due to the persistent efforts of Glenn H. Curtiss, of Hammondsport, N. Y., who produced the first practical float seaplane in 1911 and developed the following year, simultaneously with M. Denhaut, of France, the boat seaplane, or flying boat.

Particular credit for having advanced the mechanics of the airplane is due to Louis Bleriot and Edouard Nieuport, in monoplane construction; to Louis Breguet and A. V. Roe, for the development of the tractor biplane; to Gustave Eiffel, whose aero-dynamical research work placed airplane construction upon an engineering basis; to the Seguin brothers, for the invention of the rotary airplane engine, which has furthered the progress of aviation probably more than any other single development; and to Louis Chauviere, the inventor of the laminated wood propeller. With the exception of A. V. Roe, an Englishman, all these pioneers were Frenchmen. To their number may be added the Russian, Igor Sikorsky, who first built an airplane driven by several motors and thus proved the soundness of multi-engined power plants. Indeed, Sikorsky deserves unstinted praise for his foresight, and his machines were by far the forerunners of our present giant airplanes.

### What the Airplane Owes to the Great War

So thoroughly did the airplane prove its military worth on the battlefields of Europe that all possible efforts and facilities were concentrated on the development of the airplanes of the belligerents. The airplane was improved by leaps and bounds.

American aviation, which was at a very low ebb at the beginning of 1917, rose rapidly after our entry into the war. Once we got down to the business of producing airplanes and engines capable of competing with the best flying over the battlefields of France, we soon learned that other nations had little to teach us.

And we must not forget that the war made aviators by the tens of thousands. Until 1914 an aviator was a rare person; it was a great distinction to hold a pilot's license; few persons had gone aloft in airplanes. But with the call for fighting aviators, the various countries engaged trained thousands of young men for flying duty.

The past two years have seen the crossing of the Atlantic by airplanes, a flight from England to Australia as well as a flight from Rome to Tokyo, a flight from Mineola to Alaska, and other commendable achievements which would have been considered wild and even mad attempts but a few years ago.

The closing months of the period reviewed in this brief résumé of flying progress have been marked by the ap-

## Knitting Mills  Cotton Mills

***Needed in St. Louis***

THERE are unusual opportunities in St. Louis for knitting mills and cotton mills. The immense market in the great St. Louis trade territory, the nearness to raw materials, the rail and water shipping facilities meet the requirements for the successful manufacture and distribution of knit goods and textiles. The annual sales of dry-goods in St. Louis total more than $200,000,000.

St. Louis is close to the center of the cotton supply. The Mississippi River gives an unlimited water supply. Abundant hydro-electric current is obtained from the Keokuk Dam. One twentieth of all of the coal mined in the world is mined within 100 miles of St. Louis. The female labor supply is approximately 53,000. A St. Louis bleachery, now in operation, has capacity for the output of several mills. The climatic conditions are excellent.

Textile manufacture is one of the following sixteen industries St. Louis is seeking:

*Shoe laces and findings*
*Cotton spinning and textile mills*
*Dye stuffs*
*Steel and copper wire*
*Machine tools and tool machinery*
*Automobile accessories and parts*
*Drop forge plants*
*Tanneries and leather products*
*Malleable iron castings*
*Farm implements*
*Rubber products*
*Screw machine products*
*Locomotive works*
*Blast furnaces*
*Cork products*
*Small hardware*

The booklet, "St. Louis as a Manufacturing Center," gives details that will interest you. A letter will bring it. Address

pearance of the all-metal machine in peaceful pursuits. It was during the last year of the war that Germany introduced all-metal airplanes over the battlefields of France, and those Junker monoplanes were erroneously looked upon as mere freaks not worth even copying for experimental purposes. As a result the German aircraft constructors have scored a distinct scoop, to use the parlance of the newspaperman, on the world at large. Since the war the Germans have adapted their Junker monoplane to commercial work, and as such they have a most excellent six- or eight-passenger machine which has scored many enviable records. The metal airplane, which marks a new era in airplane construction, was predicted in the SCIENTIFIC AMERICAN as early as 1910, together with the retractible chassis, gyroscopic stabilizer, and other features now realized in present machines.

## Seventy-five Years of American Patent Administration

*(Continued from page 341)*

efficiency. It is appropriate that the Patent Office should have been the scene of this innovation, for nowhere else in the Government service is the character of the personnel such a vital factor in the value of its proceedings. If Commissioner Fisher demonstrated nothing eles than the efficiency and morality of the merit system, his administration would have been among the most notable. And yet this was but one of several similarly vital reforms he introduced.

### Congressional Recognition

Frequently, an executive's hands are tied by the law. Do all he can, turn as he will, progress may be denied him owing to conditions imposed by statute. Having done all within a man's power to improve the administration of the office, but recognizing the legal limitations that barred proper development, Commissioner Fisher next attempted to overcome the inertia of the law-making body. New legislation was absolutely essential for carrying into effect his ideas as gained from his experiences, and he did not hesitate to ask for everything that he deemed necessary for that purpose.

In the first place, Mr. Fisher proposed legislation which led to the publication of the *Official Gazette* and the photolithographing of copies of patents. He was also instrumental in placing on the statute book, with the powerful aid of Representative Jenckes, the consolidated patent act of 1870. This act codified the law and, in addition, presented new features tending in the direction of modernization.

The patent act of 1870 not only introduced several broadly new features but codified the laws relating to patents, and the office is now running substantially on the basis of that act. The most important innovation since that time was the creation in 1883 of the International Bureau for the Protection of Industrial Property, by which the residents of every subsidiary country have reciprocal rights in all the other countries in regard to applying for patents and the procedure connected therewith in the respective patent offices.

### The Patent Office and the Courts

Another change of momentous influence was the modification of the jurisdiction of the United States Supreme Court. Up to 1891, the highest court of the land assumed appellate jurisdiction in patent causes. Since that time, except in highly specialized instances, the courts of last resort in patent litigation are the nine separate circuit courts of appeal. There has resulted from this change, made necessary to relieve the docket of the United States Supreme Court, a confusion of principles, an uncertainty in patent rights and an inconsistency between the frequently inharmonious views of the different but equally important jurisdictions.

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

**SCIENTIFIC AMERICAN**

contains Patent Office Notes. Decisions of interest to inventors—and particulars of recently patented inventions.

A 43 Tooth Translating Gear-Wheel will turn your inch screw thread cutting lathe into metric. U. S. Pat. No. 1318045 to Jos. Becker, Address, E. Becker, 1315 Fairmont St., Washington, D. C.

**FOR SALE**

U. S. PATENT Burglar and Fire Alarm. It works automatically. Connected to doors and windows. When opening the alarm sounds at once. Write private. Mrs. Lotta Thorbjornson, Nadeau, Menominee Co., Michigan.

**INVENTORS**

MR. INVENTOR: Have you an idea that you can't work out? Get in touch with us—we will develop it for you. We are mechanical and electrical engineers, specializing in model and experimental work, developing and perfecting inventions. Designers and builders of special labor-saving machinery. Elk Mfg. Co., 1926B Broadway, New York.

**PATENT FOR SALE**

OIL BURNER for hot water kettles and wash boiler for outright sale. Reasonable price. Canadian rights as well. Something new and good—always in use. A. T. Timosci, 668 Willis Avenue, San Jose, Cal.

**PATENT DESIGNS WANTED**

WANTED. By responsible manufacturer to purchase new patented designs on various toys. Address Box 523, N. Tonawanda, N. Y.

**WANTED**

CRAYON manufacturing machinery, workable with manual as well as mechanical power. Send literature and catalogue with quotations to R. V. Paranjpe, Station Road, Sholapur, India.

**WANTED**

THE exclusive manufacturing rights of some machine, device, or article in the metal line patented or otherwise, by one of the most completely equipped manufacturing plants in Indiana. Address W. F. M.—P. O. Box No. 263, Bedford, Indiana.

**For the Highest Prices** send us false teeth, old and broken jewelry, platinum, diamonds, watches, old gold, silver, War Bonds and Stamps. Cash by return mail. Goods returned in 10 days if you're not satisfied. Ohio Smelting & Refining Co., 234 Lennox Bldg., Cleveland, Ohio

# MANUFACTURERS

A going manufacturing concern has decided to eliminate two lines—Kerosene Engines and Tractors. The engine line has been on the market for fifteen years with thousands of satisfied users. The tractor is a modern 3-4 plow, four cylinder job past the experimental stage and ready for quantity production. Tracings, Patterns, Jigs, Tools and Parts will be sold reasonably. An exceptional opportunity for a manufacturer to secure two profitable lines. Write, Box 119, SCIENTIFIC AMERICAN.

## No bumping the bumps

Garco has prevented many men from losing their heads when confronted with emergencies. It's reliable in action because it's reliable in construction. It's as tough, durable and gripping as experienced brake lining manufacturers can make it.

Garco is made of the best materials the markets of the world can provide.

The more responsible dealers sell Garco.

## Worn the World Over

For more than forty years Boston Garter has been a friend to men the world over. It not only keeps the old but makes many new ones each year. Most men ask for Boston Garter as a matter of course—the two words go so well together.

GEORGE FROST CO., *Makers*, BOSTON

But the greatest loss has been in the absence of those great decisions formerly handed down from the Supreme Court bench.

The patent system established by the act of 1836, creating the so-called "American" or "examination" method of granting patents by which scientifically and legally trained men scrutinized the technical merits of the invention, compared it with all known like efforts by an examination of every available printed record, and determined the form and legal limitations of the grant, has been pronounced to be the greatest piece of constructive legislation ever placed on our statute books. Certainly, no law designed for purely national aims has ever been copied so extensively as this. Almost every nation which has any pretension to being influenced by modern industrial tendencies, has adopted it or adapted it to its own purposes. This law thrust upon the Patent Office a substantial portion of the legal work that had hitherto devolved upon the courts. It was a radical departure from all existing systems, which merely provided for the "registration" of the application when deposited in the Patent Office, and gave the patent neither legal nor industrial value.

Under the registration system, patents were granted to others than the inventors, or for inventions that were old or inoperative. This system was tried out for 33 years previous to 1836, and created such uncertainty in the patent situation, opened the door to so many frauds, and was productive of so much unnecessary litigation, that it became more of a menace to industry than a help, and depressed the spirit of invention rather than stimulated it. England, as already stated, discarded this system.

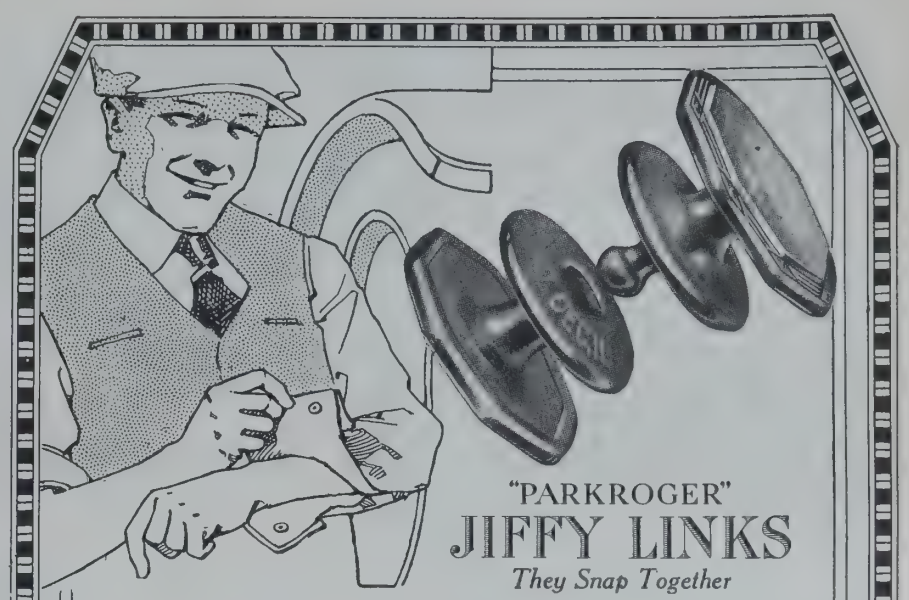
Germany and Japan, the two countries above all others in recent times which have had their eyes open to the main chance, have copied the American or "examination" patent system. No other nations ever made such conscious, deliberate and studied attempts to achieve material success, and they went to every other country to learn what it most had to offer, and did not hesitate to borrow and adopt from it what they found most of value.

### Our Patent Growth

America is the land of ingenuity, and the national genius finds its outlet in invention. As far back as 1857, the applications filed in the U. S. Patent Office exceeded those filed in England by one-third, and since the founding of this government, almost as many patents were granted in the United States as in England, France and Germany combined. The measure of the activity, however, of the Patent Office is indicated by the applications filed, and not by the patents granted. It is curious to observe in this respect how the history of the great war repeats the experience of the Civil War. The heaviest year in applications filed preceding the latter event was in 1860. In 1861 occurred a decided dropping off, succeeded by gradual gains in the following years. In 1864, with the end of the war in sight, a marked increase took place, while in the three succeeding years the business jumped by leaps and bounds.

So in the more recent event—the year 1916 saw the largest business ever presented to the office up to that time. Our entrance into the war did not make itself felt until several months later, but in 1918 its full effect was shown in a 15 per cent drop in receipts from the average of the seven preceding years. Before the year 1919 got well under way, the effect of the cessation of hostilities became apparent, and by summer the receipts began to exceed those of the heaviest of preceding years.

The intimate association between industrial progress and inventions is shown in the history of two inventions developed during the life-time of the average college boy. The automobile and the moving pic-



"PARKROGER"
## JIFFY LINKS
*They Snap Together*

WHERE do your shirts wear out first? At the *cuff edges* probably. The cuff edges soil *first* and *most*, and laundering quickly wears them out.

Jiffy Links Separable Cuff Buttons practically double the life of a shirt. They make it *easy* to turn back the cuffs and keep them clean. Made in two pieces that snap together, and apart. Buttons will not fall out when unsnapped. Hold cuffs smoothly when fastened. Made in many beautiful patterns; at various prices.

Specify "Jiffy Links" to your haberdasher or jeweler. Made by a house famous fifty years for the superiority of its products.

SPUR-GEARED BLOCK

ture were merely experimental features at the beginning of the century. Today, the film picturizations directly and indirectly involve capital employment going into the billions, while the annual output of automobile and accessory producers aggregates the amazing figure of three and one quarter billions of dollars, which is more than three times as much as the total aggregate of *all* production in this country in 1850, when we had a population of 23,191,876. The automobile has jumped Detroit in ten years from a city of the third class to one in the first class, while the "movie" has made Los Angeles a near-metropolis and given it international renown. The difference between countries influenced by invention on the one hand, and removed from its effects on the other is strikingly shown in a comparison in material welfare between United States and Russia.

### The Diamond Jubilee of the Scientific American

(*Continued from page 343*)

stitution of a carbon paper ribbon. Compliments from our subscribers came from all over the world; for when once in typewritten form there was no difficulty in transferring the matter lithographically and printing in the "offset" presses.

### The Scientific American Monthly

In 1876 the Centennial Exhibition offered such an alluring field, with its vast stores of information, that it was decided to publish the SCIENTIFIC AMERICAN SUPPLEMENT. When the Exposition closed the SUPPLEMENT was too well liked by the subscribers for the publishers to abandon it. Tihs popularity remained with the successive volumes until it was decided to bring it out in monthly form, beginning January 1, 1920, under the name SCIENTIFIC AMERICAN MONTHLY.

In the few months which have elapsed the MONTHLY has proved its worth, and is conceded to be the best scientific periodical of its type in the world.

### The Various Homes of the Scientific American

The business homes of Munn & Co. and the SCIENTIFIC AMERICAN in New York have been few in number.

First, 1845-1859, Sun Building, Fulton & Nassau Sts.

Second, 1859-1882, World Building, 37 Park Row.

Third, 1882-1884, 261 Broadway.

Fourth, 1884-1915, 361 Broadway.

Fifth, 1915 to date, Woolworth Building.

Messrs. Munn & Co. have their own building in Washington, adjacent to the Patent Office, so that the business of their clients can be expeditiously handled. Branch offices are also maintained in Chicago and San Francisco.

It is very seldom in this country that a business enterprise remains in the same family for a period of nearly 75 years. It seems appropriate, therefore, to commemorate the event in a becoming manner. The son of one of the original founders is president of the present organization and his grandson, its treasurer.

### From Wet Plate to Motion Pictures

(*Continued from page 346*)

when exposed to light in combination with bichromate of potash. This observation was first made by Becquerel. The next idea evolved was that gelatine made insoluble by light might be made to imprison particles of coloring matter. Where light acted, these would remain; where it did not act they would wash out by reason of the insolubility of the portion of the films in which they were contained. This was an important step and was made by Poitevin in 1855. The carbon process now used was invented and patented in 1866 by J. S. Swan.

### When the Dry Plates Replaced the Wet Plates

Dry plates were proposed as early as 1854 by Gaudin in France and Muirhead

in England, and J. M. Taupenot seems to have been the first to have invented a practical dry plate. His process was cumbrous. It was not until Major C. Russell introduced the alkaline developer in 1862, which necessitated the employment of silver bromide on the sensitized glass, that the dry plate really became workable by anyone. His dry plates were the forerunner of those we now employ.

Up to the time of W. B. Bolton and B. J. Sayre's experiments in 1864, silver iodide had been considered the staple of a sensitized film on which to take negatives. It occurred to them to bring the sensitive salts of silver in collodion while liquid and to form a sensitive film merely by letting the collodion, containing the salts in suspension, flow over the glass plate. Thus the collodion emulsion process was born—a process which revolutionized photographic manipulations. M. Carey Lea and W. Cooper, Jr., placed the process on a commercial basis by improvements which made the plate more sensitive.

Since silver bromide emulsion could not be prepared in collodion, naturally experimeters began to cast about for collodion substitutes. The researches of Madox, King, Burgess, but above all the work of R. Kennett and C. Bennett, from 1871 to 1878, resulted in the gelative emulsion process of making dry plates.

### The Rise of the Film Camera

Dry plates were too heavy and cumbrous for the amateur. A thin, rollable, continuous, transparent strip, which would carry the negative, was required. That need was supplied by the celluloid film which was invented by the Rev. Hannibal Goodwin in 1887. There can be no doubt that the celluloid film was also independently worked out by Eastman and his chemists; certainly the commercial film came from George Eastman and his associates.

Eastman has contributed more to present-day photography than any other worker in this field. He followed up the commercialization of film negative by developing the handy camera which he called the "Kodak." The first camera of this vast camera family appeared in 1888. It took round pictures, 2½ inches in diameter, had a fixed focus, and carried a roll of 100 exposures. Compared with the cameras of today, it was crude, to be sure; but in its time it marked a vast stride forward and started the true era of amateur photography. Later Eastman made his film cartridge light-proof, thus introducing the daylight-loading feature.

Year after year film cameras, as well as hand cameras in general, have been improved and refined. It is only a few years ago that cameras were generally fitted with simple double lenses of the rapid rectilinear type in place of the simple, meniscus lenses of an earlier period. Today practically every camera intended for anything like good work is provided with anastigmat lenses.

Again, it is only a few years ago that the autographic feature was made part of the kodaks, marking another big step in making the camera a useful article rather than a chance sport.

Space does not permit us to delve into the interesting subject of color photography, which, strange to say, is a phase of long standing. Suffice it to mention that color photography has received the attention of a host of inventors and experimenters, but even today it does not seem to have developed to a simple enough stage to warrant its universal application.

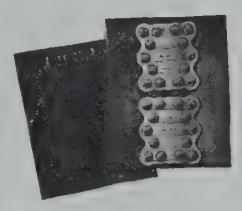
### Pioneer Days of Motion Pictures

It was the invention of celluloid film that made motion pictures possible on a commercial scale. Prior to the introduction of film there were numerous attempts at motion pictures, beginning with Dr. Coleman Sellers of Philadelphia, who took out a patent in February, 1861, for what he called a "stereoscopic cabinet," but which came to be known as the "kinemat-

**Surmounting the Mounting Costs of HORSEPOWER!**

*DOLLARS* bursting the prison of the lump of coal or springing into production from the rushing waterfall—that's Horsepower!
And in your plant every stop of their thundering means production lost, power lost and dollars lost forever.

Belts which fail because joined so their strength is impaired are a source of avoidable loss.



This is the scientific method of joining belts to maintain their maximum strength, Crescent Belt Fasteners hold—without holes. Joint runs same as endless, without noise and without strain. No metal contacts with pulleys to wear or crystallize. Joint is permanent for life of belt, yet provides easy and economical take up of slack. Write for details.

**CRESCENT BELT FASTENERS**
*Make Good Belts Give Better Service*

Permitting anything short of maximum belt life, or rejoining it while men and machines stand idle costs you power, labor, time, investment and production. Stop it. Make it creative!

Crescent Belt Fasteners standardized throughout your plant will maintain continuous production, and your belts will give better service and serve their longest life.

Write for full details in Booklet "B" on Modern Scientific Methods in Belt Joining.

A Recent GTD Advertisement

**They produce a bushel of wheat in 8 minutes**

IN 1830, says Barton W. Currie, human labor produced a bushel of wheat in an average of three hours and three minutes. Today with the aid of machines, we produce that same bushel in 8 minutes.

Quantity production is not only a matter of shops and factories, but of the grain fields where real miracles are being wrought by implements, tractors, trucks, appliances.

Improved farm machinery results from the work of modern thread-cutting tools which produce the nuts, bolts, rods and tapped holes that hold most machines together, and for production or repair of farm machinery, GTD taps, dies, reamers and gages are essential.

When next you see a tractor, reaper or simple ensilage-cutter at its work, think of the hidden threaded parts that make it possible. Then think of the GTD tools that made the threaded parts possible.

To executives, engineers and designers, who seek to produce in greater quantities, products on which they are working, GTD offers a profitable service. Send the coupon or a letter under your personal signature for "Tools and Dividends," the book of threading knowledge, especially prepared for those interested.

IT was Sir Samuel Cunard and his associate founders of the Cunard Line who really gave the first impetus to systematic transatlantic travel, eliminating its discomforts and making ocean travel an allurement to countless thousands who now speed upon their way of business or enjoyment with a feeling of comfort and luxury.

The extended intercourse and greater intimacy between the old and the new world which have naturally resulted from increased facilities in ocean travel contribute greatly to cementing those cordial relations between America and England which mean so much in both nations' progress.

For eighty years, extending over a period of four generations, Cunard liners have enjoyed the unquestioned favor of American ocean travellers, a favor which we cherish and aim to retain.

or Branches and Agencies

oscope." Because he introduced the intermittently moved ribbon-like picture carrier, Sellers is in a sense the father of motion-picture photography. Others who worked on the motion picture were Donisthorpe in 1878, Marey in 1881, and Reynaud in 1889. While all of these adopted and employed perforated picture ribbons, Marey employed the celluloid film.

The intricacies and conveniences of the camera naturally depended on the kind of plate being used. In the camera used by Niepce and Daguerre, the focusing was accomplished by sliding the lens back and forth. Daguerre, in 1839, focused his camera by having one section sliding in or out of the other. Then followed the camera with stationary front and the back sliding upon its base with a set-screw and connected with the front by means of a bellows. It remained for the American inventor, George Eastman, to simplify and refine the camera and accessories of those days so as to make amateur photography what it is today.

Credit for giving the first exhibition of motion pictures goes to Henry Heyl of Philadelphia. In 1870, Heyl exhibited his "Phasmatrope" before an audience of over 1,500 persons. The related photographs were small glass positives of selected subjects reduced from wet plate negatives, taken from successive poses, by an ordinary camera.

Then there is the work of Edward Muybridge, whose horse-galloping pictures made him famous. His remarkable studies of animals in motion were made with a battery of cameras. His work was more scientific than of commercial value. Muybridge did design, about 1880, his "zoopraxiscope" to exhibit his glass plate positives of animal movements. This was similar to Heyl's work.

In 1889 Edison made his first motion-picture camera in which the film was intermittently moved. His earliest form of exhibiting apparatus, known as the "kinetoscope," was a machine in which a positive print from the negative obtained in the camera was exhibited directly to the eye through a peephole. In 1895 the films were applied to modified forms of magic lanterns and the images projected on the screen.

Another pioneer in the motion-picture field was C. Francis Jenkins of Washington, D. C. In 1893 and again in 1894 this inventor exhibited a projector which, in its essentials, was practically a modern projector. Again Lumiere gave the first public demonstration in Paris in 1895, with his kinematograph—a combination camera-projector which exhibited pictures of remarkable beauty.

And there are scores of other workers, each contributing something to the development of motion-picture photography. And all these efforts finally resolved themselves into a standard sized film which today is in universal use. The equipment, too, has been standardized. Indeed, no industry of such magnitude can boast of more complete standardization, which feature has gone far to make the motion picture a commercial and universal success of the first magnitude.

There have been motion pictures in colors. Many attempts have been made to add color to the screen, and many of these have attained no mean degree of success. Today several methods of obtaining natural color effects are in use. It has been said by one school of the art that color pictures will rule supreme within a few years; and it has been said by an equally emphatic school that black-and-white pictures are here to stay, and will never be ousted by color pictures.

Again, there have been talking pictures, but these have not met with much success from a commercial standpoint. The main difficulty in this direction is that the technical development has not advanced to a satisfactory point. And even allowing technical success, the fact remains that the present films can get along without sound.

# $5,000 Prize Essay

## The Einstein Theory of Relativity

Mr. Eugene Higgins offers through the SCIENTIFIC AMERICAN a prize of $5,000 for the best essay on the Einstein theories so written that it may be read with profit by an ordinarily intelligent person with no special mathematical training. The competition is open to any person, without restrictions of any sort, subject to the following

**CONDITIONS:**

1. No essays shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Editor will cast the deciding vote.

20 cents in Canada

Entered as second class matter June 18, 1879, at the post office at New York, N. Y., under the Act of March 3, 1879

"We expect to finish the big dam this week. Before I leave I want to pay my respects to the Bull Dog Mack. It is the most wonderful truck I have ever seen in my extensive experience with all kinds of motor truck equipment".—*From one letter of hundreds we should like you to read.*

THE Mack is distinctively an *engineered* truck. Its supremacy rests upon three essential elements of truck efficiency—dependability, economy and endurance. It was designed to do big things in a big way—easily. That it does this is vouched for by the enthusiastic approval of Mack owners everywhere.

Distinctive Mack engineering features, combined with 18 basic Mack patents have developed the motor truck the world is talking about.

*Capacities 1½ to 7½ tons. Tractors to 15 tons*

Our latest catalogues, Nos. 13 and 39, contain detailed descriptions of the many exclusive features that have made Mack supremacy possible, together with the complete specifications of every model. Send for them today.

INTERNATIONAL MOTOR COMPANY, NEW YORK

Mack TRUCKS

"PERFORMANCE COUNTS"

# STRENGTH

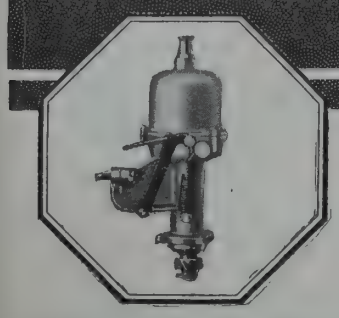
## WITH PLENTY OF MARGIN FOR THE EMERGENCY

FROM the standpoint of materials, it is reasonable to assume that every motor truck is strong. The intelligent truck purchaser can judge material strength by appearance. But continuous performance demands strength of design to supplement strength of materials. It is an honest combination of the two which enables the Clydesdale truck to serve its owner faithfully without costly interruptions.

For instance, the Clydesdale frame is of pressed steel, *shaped so that the greatest strength comes at the point of greatest strain.* It is two inches deeper than the average, and is gusseted at every corner and cross member, so that no twist of road or load can possibly bend it. Compare this construction with rolled steel frames which cannot be so shaped, and one reason for Clydesdale sturdiness is apparent. Fewer repairs and slower depreciation are worth considering.

THE CLYDESDALE MOTOR TRUCK CO.
CLYDE, OHIO

# CLYDESDALE MOTOR TRUCKS



### How This Controller Conserves Strength

The strength of most trucks is taxed to the utmost by the sudden strain put upon them when the motor is raced to get the load quickly under way. The speed of the motor is too great for the starting speed of the rear wheels, and every part is called upon to stand the shock until the speed is equalized. With the Clydesdale Controller to act on the gas supply, this cannot happen, since the motor starts the load *slowly* and picks up gradually to the speed set on the throttle. No part is jerked into doing more than its share.

# The Scare Circle

*According to the National Board of Fire Underwriters, one of the chief causes of community fires is the inflammable roof. Over a hundred cities and towns throughout the United States now have ordinances against this menace.*

SUDDENLY, without warning—Fate takes up the compass and putting down the pointer on some peaceful community, she decrees "This place shall be burned." Then swinging an arc she draws a circle—"These people shall be fear-stricken."

In the scare circle, around the fire, the horror of what might have been, brings fire prevention home to those in it and with sharpened realization Insurance is written, legislation is rushed through, fire safety devices become necessities, fire safe roofings compulsory.

And all this is perfectly human and in its restricted effect, it is the price a locality pays for greater fire safety.

But the scare circle is no longer a mere local panic. It has widened in significance, for today our fire loss is a National scandal, a cause for general concern.

Public men speak of it with grave emphasis, organized safety bodies deplore it. For fire prevention is no trumped up propaganda, no phantasy of the imagination. It is a living blight right here among us, blocking and mocking our plans to catch up in our building program; burning down ten buildings while we plan a hundred; squandering wealth; diverting labor and disturbing the very tranquility on which our development depends.

Fire prevention is a national responsibility. But it is more one of personal action than legislation. To each of us some preventative measure is possible. Each must set up his own safeguards to fortify his own property.

The spread of fire is nothing more than one building catching the flame from another, usually from roof to roof. So the roof is one of the most vulnerable spots where fire can strike.

That is why Johns-Manville Asbestos Roofing is recognized everywhere as an important prevention against fire's spread. For, it is the only all-mineral roofing felt and so while possessing all the flexibility of fabric and adaptable therefore to all kinds of roof surfaces, it is at the same time inert to fire, weather and fungi.

So Johns-Manville Asbestos Roofing either in its "built up" or "ready roll" form or as shingles, is not only fire-immune but the most remarkable of roofings. Because it is all mineral it is impervious to all the ravages to which ordinary roofings are subject.

It is economical because it lasts for the life of the building without need of repair or paint. Truly the most desirable roofing on all counts.

**The development of a new high-lift wing by British experimenters has given rise to designs for a four-ton cargo-carrying monoplane of this type, together with a system of rapid loading and unloading as here depicted**

## The High-Lift Wing and Commercial Aviation

LET us be perfectly frank in the matter of commercial aviation. We must admit by now that just so long as we stick to the present principles of design and construction, just so long do we defer the extensive employment of airplanes for passenger and cargo carrying on anything like a large scale. For it is obvious to even the layman that our present costs of operation are far too heavy to make commercial aviation commonplace. We must take it out of the luxury class to make it an everyday commodity.

Aeronautical constructors, realizing the aforementioned conditions, have been striving for years back to increase the efficiency of the large airplane, or to put it another way, lower the operating costs. Here and there certain efforts are now being consummated in the form of improved propellers, engines, and, most important of all, high-lift wings. Indeed, it seems that certain of these efforts are well along the right road and that commercial aviation is about to enter a new and more practical era.

Not so long ago Mr. Handley-Page, the well-known British aeronautical constructor, announced a new wing which had been developed and for which he claimed a considerable gain in efficiency over the usual types. And more recently a group of British experimenters have introduced a new wing which has been tried with most promising results. It is with the latter that we have to deal in the following lines.

The new wing, which has been named the "Alula," is the result of some eight or nine years of steady experimentation on small and full scale models and the expenditure of no mean sum of money. All these experiments have been directed toward producing a wing with high lifting power and low head resistance. The experimenters argued that this could only be obtained by discovering a wing which produced over its surface the type of air flow known as "irrotational" or "two dimensional"; that is to say, an air flow moving along a line which only rises or falls, but does not move sideways in a third dimension.

This type of air flow is obviously strictly parallel to the direction of flight, and so it may be assumed that none of the energy imparted to the air is wasted in side movement. The idea is, in effect, the idea of the perfect stream-lined strut or fuselage applied to the wing itself, in relation to which designers have hitherto been singularly careless in this respect.

It is claimed for the new wing that it eliminates all "end losses" and leakage, which reduce the efficiency of other wings and waste much energy in vortices. And thus it is claimed that a high percentage of the power put into the wing by the engine is given back in actual lifting power, which is as it should be in a vehicle dealing with that most elastic of all substances —the air.

As the result of the prolonged period of experimentation already referred to, it is now possible to vary all the features or factors of a wing in unison—or perhaps one should rather say, in harmony; so that when it is necessary to vary one dimension of a wing, all the other component dimensions may be varied in proportion and pre-ordained results may be obtained. It is of interest to learn that the wing shape produced resembles closely the wings of the most powerful birds, although the experimenters and Nature apparently arrived at the same conclusion by different methods.

The experimental machine, which is a species of parasol monoplane, with the wings raised above the slipstream of the tractor screw, has made successful flights. Pilots will be interested to hear that the machine equipped with the new wings refuses to obey the control of ailerons, and that it is controlled laterally by moving a hinged portion of the leading edge of each wing. This movement controls the direction of the machine as well as its lateral position, so that the rudder is not used in conjunction with the lateral control—which feature, according to our worthy contemporary, *The Aeroplane*, to whom we are indebted for many of these facts, would seem to abolish the Wright patents. Also, it is stated that if the slip stream of a tractor screw is allowed to flow over the wings, it entirely spoils their lifting power.

Actual designs have been prepared with a view to applying the new wings to commercial purposes. These call for a cargo machine to carry four tons. The proposed machine, known as the "Pelican Four-Ton Lorry," is a colossal cantilever monoplane designed for two 460-horse-power Napier engines. Its cruising speed is 72 miles per hour, its top speed 96 miles per hour, and its landing speed 55 miles per hour. Its total weight is to be 24,100 pounds. The wing loading figures out at 12.9 pounds per square foot. The useful load is four tons, with sufficient fuel for the London-Paris journey. Most interesting of all, however, is the novel system of quick loading and unloading which has been planned. This permits of handling shipments with the utmost speed, and is based on a similar practice in the motor truck field. Idle airplanes mean a large idle capital, hence the designers plan to keep the airplane in the air for the greater part of the time.

## For an Independent Naval Air Service

AS a result of the extravagance which marked our efforts to build up a powerful air service and place a large fleet of machines at the front during the late war, there is a movement afoot to combine all our activities in one united aviation service. Although powerful arguments were brought forth this year in favor of the measure, it was realized that there were many defects in the measure and the proposition was defeated.

In no quarter did such strong opposition develop as in the Navy Department, where it was felt that the propaganda which was carried on in support of the bill contained many flagrantly inaccurate and misleading statements concerning naval aviation, and that if the bill became law, it would result in taking away from the Navy the control of its own activities in the air. The SCIENTIFIC AMERICAN has already gone on record as favoring a certain measure of unification, at least so far as the matter of appropriations is concerned; but we believe the Navy is absolutely in the right when it demands that in respect to design and construction of engines and machines, in the training of personnel and in the disposition and control of its own airplane forces, it should be left absolutely supreme.

Both precedent and common sense call for the organization within the Navy of a Bureau of Aviation, which shall control its own aviation activities and coördinate them with those of the Army. It is believed that, only if the Navy has a bureau organization for aviation, will it be able to take the strong position in the air which rightly belongs to it. Failing the establishment of such a bureau, aviation will drag along in the more or less haphazard way that has characterized the development of the submarine.

Aviation is so unlike any other branch of naval activity that it is entitled to a separate bureau of its own. The design and construction of the hull of a warship is an entirely distinct activity from that of designing its engines, and the design and construction of the guns and armor are as widely distinct from both. Consequently, we have already in the Navy the separate bureaus of Construction and Repair, Steam Engineering, and Ordnance. But if each of these is so individual as to require its separate bureau, how much more so is aviation! Unlike the three mentioned, it is a new art which only yesterday was in its infancy. We venture to say that it is the most difficult of the four, surpassing them in its complexities and in the number of its major and unsolved problems. It is evident that industrially, in the preparation for war, the matter of aviation organization is of prime importance. Congress and the public are familiar with the figures giving the expenditures for aviation in the Army and Navy during the recent conflict. They know also what results were achieved. The first thought that comes to any of us when we consider the future of governmental expenditures is, how may the extravagant wastefulness displayed during the recent war be avoided if, unhappily, we should find ourselves concerned in another war. In considering the question, one fails to see any organization in effect today which is greatly superior to that which existed in 1917.

If, in the forthcoming discussion of this matter, there is found to be a general agreement that we should have a united air service, we are strongly of the opinion that such an air service should concern itself only with general coördination in the matter of the allotment of the appropriations provided by Congress. It should leave to the separate departments, War, Navy, Post Office, et cetera, the determination of all technical matters; for only the experts in these several departments are familiar with the various problems to be solved, and they alone are qualified by knowledge and experience to make the best solution.

It is particularly in this last regard that the naval authorities demand that they be given an absolutely free hand. The art which has to do with the design, construction and operation of warships is in a class by itself. Familiarity with its problems can be gained only by long and intensive training, and the problems which arise in naval aviation, whether it be in strategy or tactics, are quite distinct from the roughly parallel problems of the army service.

In conclusion, let us bear in mind that so far as production in time of peace is concerned, the number of planes produced for governmental purposes is not numerous. Moreover, since all of the work, whether for Army, Navy, or Post Office, is experimental and progressive, standardization at the present time of types of machines and mechanisms is undesirable, if not impossible. It is desirable that the various problems should be attacked by many minds rather than by an individual organization, the results of these separate efforts to be of course coördinated. We believe, moreover, that prizes and rewards should be offered to civil competitors for excellence in designs of machines and mechanisms—an attitude on the part of the Government which we believe would greatly stimulate the art.

## Safeguarding the Weapons of Science

THE horrible crime which was recently perpetrated in the heart of the Wall Street district reminds us that the powerful agencies which the developments of science have put into our hands for the prosecution of works of utility may be used by vicious and depraved minds for wholesale destruction of life and property. It is but small consolation to realize that this tragedy will concentrate public attention upon the fact that the manufacture, sale and use of high explosives must henceforth, in the interest of public safety, be surrounded with a double safeguard. The unfortunates who were killed and mutilated will have died and suffered in vain if the authorities do not take up this whole question and enact legislation that will make the repetition of such crimes extremely difficult, if not impossible. Offenses like this remind us that the benevolent fruits of our progress in discovering and manipulating the forces of nature have something of the effect of a two-edged sword. Directed to their proper and intended uses, modern inventions have done more to promote material comfort in the past century than was achieved in all the previous history of the world; but we must not forget that in the hands of the depraved and vicious, these same inventions may be used with deadly and far-reaching effect as instruments of malice and revenge. The criminal who breaks into the home goes armed with the finest automatic weapons, and rarely today is the robbery of a bank attempted without the accessory of a waiting automobile at the sidewalk.

It is one of the baneful legacies of the war that it has furnished the criminal with more deadly weapons such as poison gas and the hand grenade, and it takes no great stretch of the imagination to conceive of the airplane being pressed into service as a sure means of obliterating the trail of the man who has taken the life or seized the property of the law-abiding citizen.

The use of modern inventions for criminal purposes has been foreshadowed by more than one of the popular scientific writers of fiction. We can all remember with what frequency during the war both sides were credited with having made use of virulent germs as a secret and deadly means of exterminating the enemy population; and to the lunatic as distinct from the more positively criminal type this agent of destruction might make a particular appeal.

Now it should not be beyond the resources of our highly developed civilization to find ways and means of restricting the more potent and deadly substances and appliances to their proper uses. It may be found that to do this would involve a strict supervision of the individual citizen and a certain restriction of his individual liberty. If so, he can comfort himself with the thought that it is a universal law of life that the many may be called upon, at times, to suffer discomfort because of the vicious tendencies of the few. To the law-abiding citizen, the thought of close supervision is unpalatable, if not repulsive; and it is not likely that in the immediate future we shall come to any such conditions. Nevertheless, the experience of the two years which have intervened since the armistice proves beyond a doubt that crime is tending to make an increasing use, or rather misuse, of the weapons which, largely as the result of the war, have been thrown in its way.

There has always been a strong prejudice among us against the methods of police registration and supervision which have characterized some of the countries of Europe; but our prejudice has been mainly against the motive of this rather than against the supervision itself. Certainly there is something wrong with the present conditions when one man, or several criminals working together, can prepare a huge bomb, load in on to an open wagon, haul it at the busiest hour of the day into the most densely crowded center of the city, and there set it off, all apparently according to carefully calculated time and schedule. If any scheme of general registration can successfully combat this sort of thing, it is a cheap price indeed to pay for the safety of society.

## Rounding Out the State Barge Canal

THE State Barge Canal as an engineering structure is an accomplished fact. Although the work remaining to be done is of a subsidiary character, it is of a kind that is absolutely essential if the canal is to realize its full traffic potentialities. This work consists in the construction or completion of proper dock facilities not only at the terminals on Lake Erie and at the Port of New York, but also at the various shipping points along the canal.

Foremost among these works is the provision of suitable terminal grain elevators at Buffalo and New York; for it must not be forgotten that it was largely the Erie Canal which gained for New York the position which it once held in the grain trade. It has long been realized that before private capital will build the necessary barges the State must provide terminal grain elevators designed especially to accommodate barge canal traffic. The existing grain elevators are owned by the railroad companies, and naturally the grain that comes to New York by railroad will have the first call upon these facilities.

For these reasons, those who are anxious to see the grain trade to this city win back its former position will welcome the announcement of the State Engineer that the plans for the public grain elevators have been completed and will soon be presented to the Canal Board for approval. These plans, which have been approved by a committee appointed by the New York Produce Exchange to coöperate with the State Engineering Department, are to have a capacity of 2,000,000 bushels of grain, with provisions to increase this whenever future developments of traffic call for it.

It is gratifying to know that the Barge Canal is proving to be adequate and efficient, testimony to this fact having recently been furnished in a report by a corporation which is operating fleets of modern steel barges on the canal and which contemplates extensive additions to its facilities in the near future. The report states that the vast possibilities of the canal as a link between the Great Lakes and the sea were duly considered by the officials of the corporation while its barge fleets were in contemplation. Each unit of its fleet averages eight days between the Hudson River and Lake Erie. These units consist of four barges of 400 tons deadweight, each towed by a steam tug, the fleet moving as much as could be carried in three train loads of 50 cars with a minimum of twelve tons in each car. The company states that the buoying of the canal and its general upkeep is very satisfactory, and it is believed that America's inland waterways will be second in importance within a few years' time to the present great development in deep sea shipping.

## Electricity

**Simplifying the Radio Telephone.**—There has recently been introduced a radio telephone outfit which operates without a "B" battery or external source of high potential. The entire outfit may be readily transported. The transmitter weighs 60 pounds, including two six-volt storage batteries. It operates with any suitable type of receiver and audion detector, with or without an audion amplifier, depending on the range, loudness and so on. The set is designed to operate an antenna whose capacity to earth varies from 0.002 mf. to 0.0007 mf., although it may be used on even smaller antennæ.

**Electric Heating in Switzerland.**—An authority has recently undertaken an analysis of the heat energy required in Switzerland's climate and finds that on an average 2,500 kilowatt hours per person in the winter season will be sufficient for heating not only residential apartments but also offices, factories, and so on. For the heating only a total of 10,000,000,000 kilowatt hours would be required per year in Switzerland, or just one-half of the maximum total of hydraulic energy which could be utilized per year by careful development of all available waterfalls. A difficulty with electric heating is the seasonable demand, which prevents a high economy. The author does not expect a general application of electricity for heating purposes.

**Electric Vehicle Progress.**—A rather complete survey of the electric vehicle field is presented by F. Ayton in a recent issue of *The Electrician*. It is stated that in England the superiority of the electric truck for delivery and other service in urban and suburban areas has been admitted. Moreover, the soaring cost of fuel for the internal-combustion engine, not to speak of the extremely heavy cost of keeping in repair vehicles fitted with this type of motor, is giving a greater and yet greater advantage to the simple and economic "electric." These facts apply to conditions in England, of course, where fuel is exceptionally high. Attention is also called to the DeMartis lead type of "lead-acid" battery of Italian origin, in which it is claimed that by the use of a special paste which combines extreme hardness with great porosity, formation of lead sulfate is prevented. Other advantages claimed for this battery are higher capacity for the same weight, slightly higher voltage on discharge, and increased watt-hour efficiency.

**Why Not Electrify Railroads Now?**—It is the consensus of opinion among manufacturers of electrical equipment and supplies that the next year or two will see a great boom in the electrification of our leading railroads. Now that the railroads are facing the stern necessity of purchasing new equipment not only to replace that which has become obsolete, but also to take care of the increased traffic, it would seem that the opportune moment has arrived for electrification on a large scale. Ultimately, it is argued, the railroads must come to electric operation, and the longer they put off the conversion the more equipment they are certain to pile up against the day when it must be scrapped. Furthermore, electrical men claim that the increased efficiency of electrified railroads would go a long way toward making up the cost of the change at this time. The main deterrent at this moment seems to be the financial situation, which does not favor the expenditure of vast sums of money on anything which does not promise an immediate and profitable return. Nevertheless, it would appear that the ultimate economies to be attained through electrification are sufficiently attractive to make it decidedly worth while for our railroads to go to some effort to take advantage of them; so we look for at least partial electrification on a notable scale in the near future.

## Science

**Eruption of a Geyser in France.**—A French geologist, M. Glangeaud, has transmitted to the French Academy of Sciences a report on a geyser-like phenomenon recently produced in the course of the boring of a well in search of petroleum on the plains of La Limagne. The hole had reached a depth of about 500 feet when there was a sudden eruption of boiling water, which rose above ground in a jet 130 feet high and hurled the boring tools, weighing two tons, into the air. Hot water was still flowing from the well at the time of the report. The water, which has been analyzed, is highly charged with carbonate of soda and other salts, as well as carbon dioxide.

**The Velocity of Explosive Sounds.**—The sound-waves produced in air by a sudden explosion travel at first faster than do ordinary sound-waves. Some interesting experiments have recently been carried out by Dr. Dayton C. Miller for the purpose of obtaining exact data on this point. The experiments were made during the firing of large guns, mostly 10-inch and 12-inch rifles, at the Sandy Hook Proving Ground. The amount of powder charge and the value of the internal pressure developed in the gun were taken into account. The sounds were received by specially constructed carbon-granule microphones, and by others of a very sensitive type. The records were made by a moving-film camera in connection with a string-galvanometer capable of recording from six stations simultaneously; the same type of apparatus used by the army for sound-ranging. Stations were located at the muzzle of the gun, and at various distances up to 21,000 feet. Detailed meteorological observations were made during the experiments. Dr. Miller's investigations prove that the velocity of the explosive sound at a distance of 100 feet from a 10-inch gun is about 1,240 feet per second, or 22 per cent above normal. At 200 feet it is only about 5 per cent above normal. For all distance above 500 feet the velocity of the sounds produced by the largest sized gun is practically normal.

## CONDITIONS FOR THE $5,000 PRIZE EINSTEIN ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Essay Editor will cast the deciding vote.

## Aeronautics

**Aerial Transport in Kongo.**—A dispatch from Brussels says that the mission charged with organizing aerial transport in Kongo, Africa, is actively continuing its work. The first hydro-airplane flight took place some time ago between Kinshasa and Bolobo. Belgian aviators covered a distance of 200 miles in a little over two and a half hours.

**A New High-Lift Wing** known as the "Aulula" wing is now attracting wide attention among British airmen. The wing is the result of some eight or nine years' patient research work on small-scale and full-scale models. All these experiments have been directed toward producing a wing with high lifting power and low head resistance. It is claimed that the new wing eliminates all "end losses" and leakage which reduce the efficiency of other wings and waste energy in vortices. It is this feature which makes for an enormously high percentage of actual lifting power.

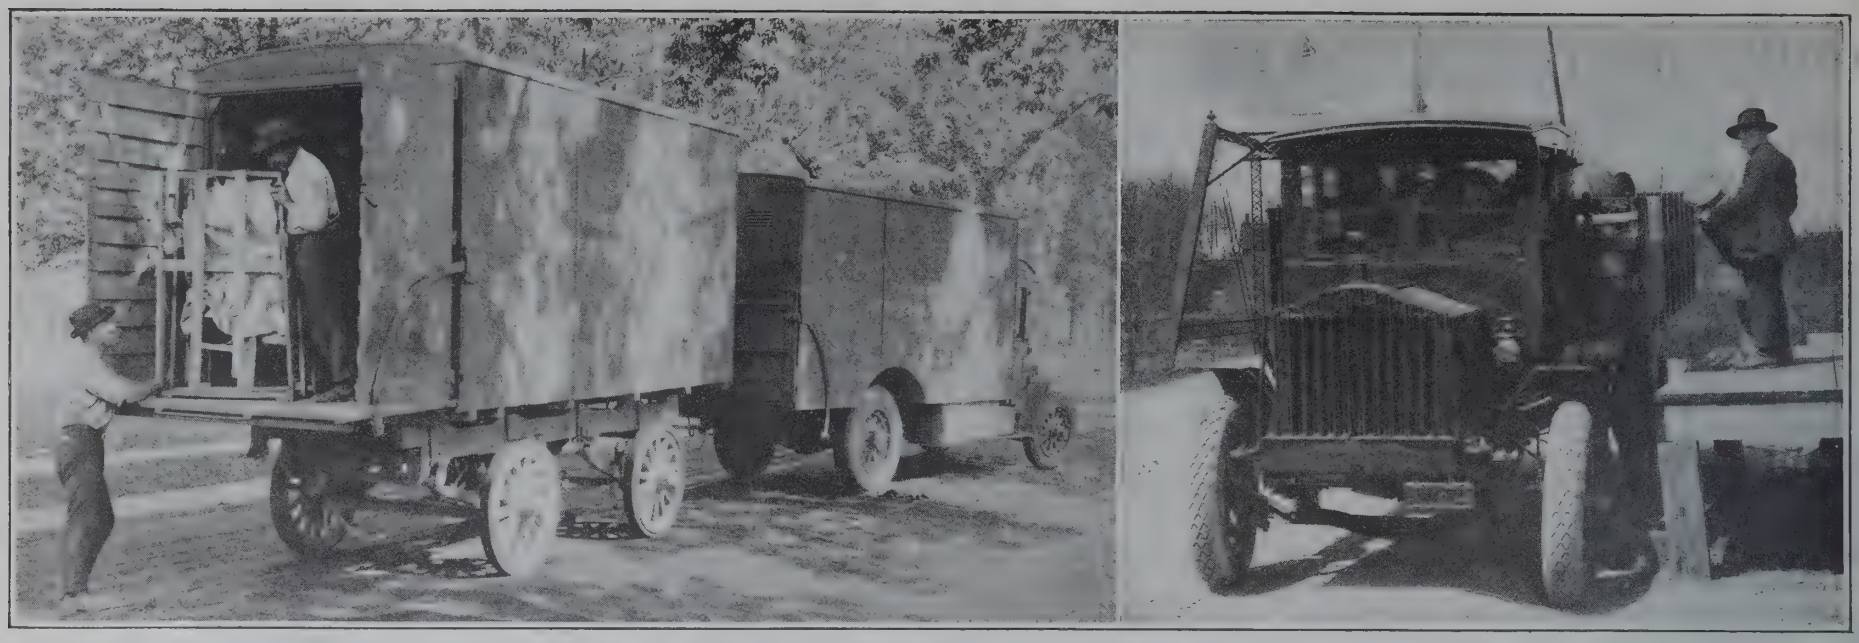
**American-Built Junkers Monoplanes.**—From advertisements which have recently appeared in the aeronautical press, it is learned that the Junkers all-metal monoplane is to be constructed in the United States at an early date. It will be known as the J.L.-6, and built under a patent license granted by Dr. Hugo Junkers of Germany. It is claimed that the machine will carry six to eight passengers at an average speed of 112 miles per hour with a 160-horse-power engine.

**An American Torpedo Plane.**—Carrying a crew of four men and a 1,600-pound torpedo, a Martin bombing plane fitted with torpedo gears recently flew from Washington to Yorktown, Va., a distance of 125 miles, in 64 minutes. Naval officers declare the flight established a record for planes of that type. The flight, continues *Aerial Age Weekly*, was made as a test of the Martin plane in connection with its use in the bombing and torpedo practice soon to be conducted with the old battleship "Indiana" as a target.

**Smoke Screens from Air Bombs.**—Tests conducted by representatives of the Bureau of Ordnance, Navy Department, with smoke bombs designed to lay a smoke screen for naval vessels from aircraft, proved that a satisfactory screen can be laid in this manner. Experimental models of smoke bombs weighing 50 pounds were tested recently, and after the experiments it was agreed that a bomb weighing not less than 100 pounds would prove to be more satisfactory for the purpose for which the experimental models had been designed.

**Timber Land Inspections by Airplane.**—Traveling 200 miles in 144 minutes, part of the time circling low to note the destruction done by forest fires in the Yakima district, Washington, Aviator R. I. Ehrlichman of a local lumber company, accompanied by the vice-president of the company, recently inspected the timber holdings of his organization by airplane. The aerial inspection is reported to be a highly satisfactory means of making a rapid yet sufficiently complete survey of timber holdings.

**Zeppelin Activities.**—A few weeks ago Germany delivered a brand new Zeppelin, the largest yet built, to France and another new Zeppelin to Great Britain. Yet we are told by *The Aeroplane* that Herr Colsmann, the director-general of the Zeppelin interests, recently returned from the United States after negotiating with certain firms regarding transatlantic air traffic. Negotiations have also been carried on with Holland, Sweden, and the United States for the construction of airships on an international basis. It is rumored that a new type Zeppelin airship, with a load capacity of 60 tons, accommodation for 500 passengers and fuel capacity for a voyage three times the length of the Atlantic crossing, is to be evolved.



*Left:* This interurban express line running out of Milwaukee makes use of the truck and trailer system. The service extends as far as Madison and Beaver Dam, and is said to be operating at 100 per cent capacity in picking up and delivering package freight of all kinds to farmers along the route. *Right:* A truck of a Detroit milk company making the rounds of the rural districts. Over half of Detroit's milk supply is now being brought in by motor truck

**Two instances of how the motor truck is filling a very important gap in the Nation's transportation system**

# A New Deal in Transportation

## Relieving the Railroad of the Business Which It Is Least Able to Handle

### By Col. Jesse G. Vincent, Vice-Pres. Packard Motor Car Co.

WE have reached the point where congestion of terminals and tracks has begun to apply the law of diminishing returns to railroad freight traffic. The situation is greatly aggravated by the immense shortage in freight cars. Together, these have brought about a partial failure in our transportation system that is causing great loss—loss to the roads themselves, particularly in short-haul, less-than-carload freight, loss to the shippers, and loss to the general public by reason of the increased cost of living and the impossibility of delivering products promptly at the point where they are needed.

Into this situation the motor truck is coming as a means of salvation. It is only a few years old, and has been fitted for its task even more recently, through the grueling strains suddenly put upon it during the World War. Although it is barely beginning to serve, it has proved itself possessed of the power to save money for the public, the shipper and the railroads at one stroke, besides solving the transportation tangle by lifting the burden which presses most heavily on the railroads, that of short-haul, less-than-carload freight.

A more or less permanent shortage of 100,000 freight cars which has existed for several years back puts additional stress on every discussion of this new movement in the transporting of the country's freight. And little promise is held forth for early relief from this serious freight car shortage. According to *Railway Age*, there will be needed in this country during the next three years, if provision is to be made for the inevitable growth of shipping and the retirement of worn-out equipment, a total of 712,400 new freight cars, not to mention locomotives, signal apparatus, track maintenance material and sundry other rail supplies in similar quantities.

Many trustworthy authorities contend that it will be utterly impossible to construct this large amount of new equipment rapidly enough to satisfy the shipper's needs. Surely, the contention is not far from logical if we may take as a criterion by which future production may be predicted, the freight car output for 1918, computed from statistics of the Railway Administration, which show that during this year deliveries were made on an order for 100,000 new freight cars at the rate of only 61,000 units per year.

The seriousness of the situation and the tremendous cost to both the shippers and to the public are at once apparent. The harmful influences of congestion reach into every producing center in the country. A prompt turn-over of freight is out of the question. Consequently, excessive credits are required to carry the burden of distribution through its cycle. Production is severely crippled through the lack of raw materials and as a direct result of this prices are increased.

All of these things arise from inadequate transportation and must be corrected before the country can return to a normal condition so far as the movement of freight is concerned. Some of this improvement will come naturally through the reorganization of the railroads, but it cannot all come from these quarters. Those who study traffic conditions closely are beginning to realize that no amount of expansion beyond a certain economic point can be of any profit, either to the railroads, to the shippers or to the public. Their deduction is based upon a law that heretofore has not been applied to railroad traffic, being confined solely to production problems. The law is known as the law of diminishing returns.

At first glance, any presumption that the motor truck as a means of moving the country's freight will meet its greatest opportunity after a given section of the country is so thoroughly developed from the railroad standpoint that no further advances are possible, seems grossly inconsistent; but, as a matter of fact, something of this kind is very liable to come about. Judging from conditions as they exist in the crowded eastern and northern States, this law of diminishing returns is beginning to operate.

The industrial section of the country, lying to the north of the Ohio River and extending eastward to the Atlantic, has been described as being literally nothing more than a huge switch yard in which the routine of keeping freight moving rapidly and of administering the countless details of short hauls and numerous transfers or trans-shipments, is becoming more and more difficult as time goes on. In this part of the country, a railroad report for a month in 1917 showed, under the stress of war-time production, the average daily freight our mileage of 25 miles was reduced to but 18 miles.

Undoubtedly there is a certain point in the expansion of railroads where such a penalty is paid. Obviously it does not apply to all localities, but there is no question but that it does find favorable soil in the crowded north-east territory, where the railroad has had the greatest growth in answer to the ever increasing industrial growth of the surrounding country.

The most significant fact of all is that so far as transportation experts can see at the present time, the law of diminishing returns creates a permanent barrier which the railroads will never, for simply physical reasons, be able to surmount. The more the trackage and the larger the number of terminals, the more the congestion will be aggravated and the slower the movement of freight will be.

So far as the money-making ability of the railroads goes, it will not be hampered in the least by a far wider adoption of motor trucks; for these motor trucks in practically every instance will be handling freight which could not be accepted at a profit by the railroads.

For many years, less-than-carload freight has been a skeleton in the railroads' closet and a very real cloud over the profit and loss sheets. Less-than-carload freight has never been catered to by the railroads. They have never been slow to realize the impossibility of securing an adequate profit on shipments which involve one or more transfers, with trucking and handling charges incidental thereto, before delivery to the consignee can be made.

Profits to the railroads come from long, uninterrupted hauls, such as those far-sighted pioneers of the Hill and Harriman school prepared for when they laid lines through the desert wastes of the West to reach the active Pacific Coast region.

One very definite advantage that will come to the railroads themselves through the increased use of trucks in handling short-haul freight, will be in connection with what are known as "feeders." These short lines are almost all of them unprofitable and many are able to subsist only through charging extremely high freight rates. They are intended for no other purpose than to bring in, to the trunk lines, freight that will prove profitable on long hauls; and this long haul freight, therefore, has to bear the burden of an actual loss to cover transportation over the "feeders."

Truck lines will almost certainly in due time take the place of the "feeder" roads with benefit to all concerned. They will, in almost every case, reduce the cost of freight and they will give a more flexible service. They also are infinitely below the cost of even the lightest branch railway for installation and they can be put in at thousands of points where it

(*Continued on page 389*)

*ONE of the most satisfying things about the progress of applied science is the way it has of always producing, as though from a conjurer's hat, the exact appliance that civilization needs at just the moment when the need appears. History is full of the stories of sudden developments of new inventions in a way that appears almost miraculous until a study of conditions shows that the world was exactly ready and waiting for the particular invention in question. We are today witnessing the beginning of just such a development in the transportation field, in the entrance of the motor truck into the short-haul business. This is a story that is more or less familiar to most of us, but few of us will fail to find food for reflection in Col. Vincent's treatment.*

## Applying Radium to Cure Man's Ills

By H. A. Mount

THERE has been much popular interest recently in the purchase by the State of New York of two and a quarter grams of radium for use in medical research work. Aside from being the largest single transaction in the precious material ever recorded, the sale price being $225,000, the incident holds a vital interest to thousands of sufferers from cancer and other malignant diseases, for the radium is to be used largely in fighting this dreaded malady.

Every year in the United States approximately ninety thousand persons die of cancer, the second disease in deadliness. Radium has long been used successfully in fighting cancer and similar malignant conditions, such as tumors, and for treating growths of a benign nature, including the removal of birthmarks. Radium has also been used in the treatment of rheumatism and neuralgia and for diseases of the kidneys and liver and certain disorderly conditions of the digestive tract.

At the left is the lead case in which the radium is carried. Below is a plaque for applying radium to skin and surface afflictions. The round disks are metal screens. At the right is an applicator, dissembled, with screens. At the extreme right the insertion of an applicator into a screen is shown

**How the medical profession makes use of radium as a tool in curing human ills**

The interest of the ordinary individual in radium is matched by a profound ignorance of how it is used in medicine and perhaps a brief exposition of methods will not be amiss at this time. There is nothing particularly new in the facts recorded here. The man who wishes to go more deeply into the subject will find many books on the therapeutics of radium in the libraries. There has been no important widening of the field of usefulness of radium in medicine in recent years, but the technique of its use has improved wonderfully and the results today are far more valuable than a few years ago. It is in this connection that the purchase by New York State is expected to be of especial value.

Radium, as used in the hospital, is not a medicine or a "cure." It is a tool—just as much a tool as the surgeon's knife; and it requires just as much skill and knowledge to use it successfully.

It is a matter of common scientific knowledge that radium emits three kinds of "rays," designated as Alpha, Beta and Gamma rays. The Alpha rays, which compose about 85 per cent of the total, have very little penetration. A sheet of tissue paper will stop them. The Beta rays, composing 10 per cent of the total, will penetrate about 35 millimeters of lead. Both of these are not really "rays," but emanations from the radium itself. They are tiny particles shot out at terrific speed and force, the fastest traveling at about one-fifteenth the speed of light. The third "ray," the Gamma, is really a "ray" or vibration similar in action and effect to the X-ray, excepting that the wave is shorter and "harder." It travels with about the speed of light. It is this Gamma ray which is useful in surgery.

It has been found that this ray has the effect of destroying, or dissolving, useless tissue exposed to it. Good tissue has a much greater resistance to its effects, usually being about a fourth as susceptible to the rays as useless tissue. After the first exposure to the rays, even useless tissue, however, builds up a resistance to the effects. It is the object of the physician, therefore, to expose the part to be treated to a maximum intensity for the longest time possible without affecting the good tissue.

There is no pain or other effect immediately noticeable from the exposure. But if the treatment has been effective, the growth will gradually disappear in time which may vary from a few weeks to several months, depending upon the nature of the growth and the physical condition of the patient. Subsequent exposures may be made but the first is depended upon to accomplish the principal result.

By means of the electroscope it is possible to measure to a very fine degree the strength of the radium "rays." The rays, of course, are always constant and this represents a distinct advantage over X-rays, which may fluctuate in volume.

The amount of the "dose" can be accurately gaged by determining the size and location of the tissue to be treated, the distance from the spot the radium is to be held, and the nature and thickness of "screens" which are placed between the radium and the flesh.

The usual method of application is to place the little

## Putting Paper on a Specification Basis

By G. H. Dacy

AT present the paper question is one of the paramount issues of the day with the most critical news print shortage ever experienced. Everywhere throughout the country advertising is being curtailed to the minimum point while all news material which is not of vital importance is being reduced to the smallest possible space in order that the available paper stocks may be conserved. In view of the paper economy campaign which is being preached and practised rigorously and well, the official data determined by the Federal Government in its various paper making and handling operations are of special interest at this time.

Annually the various government departments use approximately 50,000 tons of paper and in order to insure that this huge volume of paper corresponds in every respect to the specifications according to which it was purchased, Uncle Sam submits the stocks to many scientific and accurate efficiency tests. The paper is subjected to many physical and chemical tests as well as micro-analysis.

By means of the chemical tests it is possible to ascertain accurately the amount of resin sizing that is in the paper and the amount of filler and loading which has been added to give the paper bulk, capacity, finish and surface. The physical tests permit of determining definitely the weight, thickness and bursting strength as well as the folding endurance and tensile strength of each variety of paper which is tested. Last year, the Bureau of Standards, which performs the paper testing activities for the Federal Government, subjected 5,000 samples of paper to 19,545 official tests.

The "sizing" of the paper is the property which makes it possible to write upon it with ink. The methods now in use for determining the sizing of paper stock are not very satisfactory from a laboratory or mill-control standpoint and, on this account, Uncle Sam's scientists are now busy trying to devise more satisfactory tests. Furthermore all the available apparatus for ascertaining the bursting, tearing and tensile strength of paper are under investigation by careful and experienced experts so that they may, as far as possible, standardize the paper testing situation.

The Bureau of Standards has installed a miniature but complete paper mill on which it has tested out various fibers, weeds and grasses for paper making. The indications are, from the results thus far obtained, that wood pulp is the most dependable source of paper as various economical factors operate in one way or

# What About Our Wheat Production?

## A Concrete Suggestion as to How We May Produce More by Producing Less

By H. A. Crafts

THESE are times that demand the consideration of vital questions only. And at this time, as always, there is a paramount vital question.

What is the paramount vital question of today? It is not war, because wars of any great magnitude are over for many years to come. Wars being over, peace comes automatically, regardless of diplomacy or parliamentarism.

The Great War has been over for nearly two years now, and parliaments and peace conferences have been laboring night and day at the framing up of a paper peace, yet they have so far failed to reach an agreement that they have been able to put into effect. Yet comparative peace reigns throughout the world today. And here we have a shining example of the superiority of physical forces to moral forces.

If we search a little we shall discover that our paramount vital issue lies, not within the realm of politics, but within the domain of economics. And within the domain of economics we find the matter of human subsistence looming above all others.

The world's food supply must be the first great problem to be solved. If the law of supply and demand still endures in the commercial world the very high cost of living of today should go to prove that the world's food supply is far below the normal demand. In our own country there exists a condition of apparent plenty, yet food prices are exceedingly high. In Europe incipient famine and exorbitant food prices go hand in hand.

What are the chances of overcoming this overshadowing world menace? It is very probable that we have not acquired an adequate conception of the frightful condition of physical, moral and financial exhaustion that Europe was left in at the time of the signing of the armistice. And even Europe's remaining strength is being taxed by revolutions, and counter revolutions. Even in pre-war times Europe fell far short of producing her own food supply; then how much less able is she today to feed her own people than before the fateful day of August 4th, 1914!

Upon whom then will fall the burden of making up this appalling deficiency in the world's food supply? Upon us of the United States, and upon almost none other. We have already sustained enormous sacrifices in stricken Europe's behalf, yet the end is not. We must go on, and on in this work of world philanthropy; yet at the same time we must safeguard our own interest.

Europe saw fit to plunge headlong into a fratricidal conflict, and must expect to suffer the awful consequences of her mistake; yet we must not stand aloof and see her utterly perish, and the innocent suffer the pangs of hunger. Then how about our own ability to cope with this vast and vital problem?

The whole onus lies with the American farmer. The individual farmer may do much of his own volition. But it appears to me to be more a question of farm policy. New cultural methods may be introduced and be of large value. But more important than all is general enlightenment, coördination of economic and intellectual forces, and coöperation in the field of general effort.

The American farmer has various obstacles in his way, among which are a shortage of farm help, antiquated methods, and soil impoverishment. On the other hand a careful survey of conditions will show that there are certain phases of the industry that are of an encouraging nature.

One of these is the invention and introduction of an entirely new order of farm machinery; the general supplementing of animal power by gas power, etc. Such a power has already begun, and is working with a tremendous impulse. Its possibilities rise before the mind's eye to stupendous heights.

But of equal, if not of more, importance is the refertilization of our cultivated farm areas, which for the past half century have been drawn upon almost without limit, with no compensating return to the soil of fertilizing material. How is this to be done? The use of stable manure, commercial fertilizers, or of any other class of ordinary fertilizer, is out of the question. These materials as fertilizers are on a par with the old farm horse and plow, as compared with a modern farm tractor. We must get back to nature.

What are the elements that make fertile our virgin forest clearings, our plains and delta lands? Why, the falling leaf, the withering grass, and the profuse rootage of growing forests and verdant plains, forming that element we call the turf, and these in their decayed or incinerated state.

Why do not our forests languish and our plains become sandy deserts? Because in Nature's great system of economy they manure themselves with their own substances.

But of course there are other aids to natural growth; the sunshine, the wind, the rain, and various other phenomena. All of these are also available for the nourishment of cultivated growing crops. Therefore it is the farmer's duty to follow the example of Nature, and make his land manure itself.

This must be done by methods already known to most farmers, and practised by many. The art of green manuring, and of the scientific rotation of crops, to my thinking may be easily made to bring about the solution of this most momentous problem.

To emphasize the stern necessity of instituting this reform in our agricultural methods it is only necessary to cite the history of a single cereal—wheat. Wheat as the world's principal bread material had its acid test in the recent food shortage in Europe. We gave up a portion of our white bread, and ate various kinds of war bread, that our allies across the water might not be deprived of their wheat bread. We swallowed it with Spartan hardihood—this war bread, part barley, or rye, or corn, or rice, but when the old pure white loaf came back again it filled our hearts with rejoicing.

*THE exhaustion of the world's wheat fields and the moving of the wheat grower on to new territory is an old story. But it seems that he cannot move on forever without coming to a jumping-off place; and the performance of the past few years would indicate that just at a moment when the world's need for bumper wheat crops is most acute, this jumping-off place comes in evidence. It is therefore in order to ask what else we can do, to increase wheat production, than abandon the old fields and pass on to new. One answer may lie in the direction of farming on a sufficiently intelligent basis to prevent the soil from being exhausted of the elements that make for wheat production. Mr. Crafts puts forward two very concrete suggestions as to how this might be done, and at the same time makes properly clear the general principle on which both these suggestions rest.*—THE EDITOR.

Wheat is the premier bread cereal of the world, and stands today fixed and firm upon its economic pedestal. What is the United States doing in the way of producing this supreme bread material?

It is not the aggregate yield of the country that we must look at, but rather the yield per acre. Under war urgency the country produced about one billion bushels of wheat in 1918. But if the yield per acre for that year were sought it would doubtless make a poorer showing than in any year in the country's recent history. In California, for instance, there were thousands of acres sown to wheat that produced no harvest at all, by reason of severe drouth. And these acres must be counted in when we come to reckon the average yield per acre; for it is the number of acres sown that must be taken as the basis of reckoning, and not the number of acres harvested.

Then let us take the country's wheat crop of 1916 as being the nearest to normal. The acreage is given as 52,785,000; total yield, 639,886,000 bushels; average yield per acre 12.1 bushels. This places the United States even below reactionary Russia in its average wheat yield per acre, a sad commentary upon the progressiveness of our country, supposed to be the most progressive in the world.

But when we take up the cases of individual States the showing is even worse. Let us consider the average yields of wheat per acre of some of the supposed great wheat producing States for 1916: North Dawota, 5.5 bushels; Minnesota, 7.4 bushels; South Dakota, 6.8; Kansas, 12; Missouri, 8.5; and so on.

The States showing the best yields of wheat for that year, strange to say, were come of those New England and Middle States, whose agriculture is supposed to be in a moribund condition. Maine's average yield per acre was 27 bushels; Vermont's, 25 bushels; New Jersey's, 20 bushels; New York's, 21 bushels. So it seems that the culpability, if such it be, lies with the great West, supposed to be the store-house of the nation. And all this is due to an almost total disregard for one of the great fundamental principles of sound agriculture—refertilization. How about the remedy for this menacing evil?

Two examples that have come under my personal observation will suffice as finger-boards, pointing the way to reform in our agricultural methods.

For a period of twenty-three years I was a resident of northern Colorado, and observed quite closely the evolution of farming methods in that section. First there developed a great system of irrigation, which, coupled with an extremely fertile soil, opened a rich field for agricultural enterprise. At first the almost universal crop raised was wheat; because there was a great mining state round about which was drawing a large influx of settlers from all over the world, demanding a commensurate food supply. Railroad tariffs from the Missouri River were high, and this acted as a protection to the Colorado farmers. Colorado wheat struck a level of two cents per pound, and maintained it for a number of years.

The new lands, under the combined influence of fertile soils, ample water supply and a favorable climate produced wonderful crops of wheat—say from forty to sixty bushels to the acre. The farmers got rich. But they made the fatal mistake of following a course of blind opportunism. They sowed their fields to wheat year after year, with no rest, no manuring, no rotation of crops. The yield of wheat per acre dwindled from year to year until the average was only about eighteen bushels to the acre.

Meantime competing lines of railroad flung their tracks of steel across the great plains and railroad freight rates melted away beneath the hammering of rival lines. Wheat fell to a cent and a quarter per pound, and the farmers got poor. Some "pulled up stakes," and pushed on over the divide to Oregon; others stuck it out. Then the question arose as to what the Colorado farmers could raise, and make a profit.

A certain dealer in flour, feed and seed in Fort Collins had heard about alfalfa and its wonderful properties as a forage crop. So he sent to Los Angeles for a sack of alfalfa seed. It happened that this dealer was the owner of a ranch near town, and there he took his sack of alfalfa seed, and tried it out on his own account. It produced beyond anything that he had dreamed of.

His fellow ranchers, without knowing just how they could dispose of alfalfa at a profit, even should they produce it, began to plow up their run-out wheat fields and sowing them to the new forage plant. In a few years the country round about became green with alfalfa verdure, and literally loaded with alfalfa hay in barn and stack. But there was no special demand for the product, so the farmers began to plow under their alfalfa and to try wheat once more.

And behold! The wheat produced unexpected stands; in fact it grew so rank that it "lodged," or "fell down," to use some common farm phrases. So the farmers were compelled to plant some less susceptible crop on their alfalfa lands for a year or two; such crops as potatoes, sugar beets. Then wheat was tried again and it went back to the old virgin yields, and some better.

Naturally it became the desire to continue the growing of a crop that would produce from seven to nine tons of hay to the acre in a single season and at the same time enrich the land upon which it was grown.

By a mere accident again a way was discovered—the feeding of spring lambs from the ranges, for the Chicago market, upon alfalfa hay and corn shipped in from Kansas and Nebraska. Here was an entirely new industry that soon grew to large proportions, it being no uncommon thing to see half a million head of lambs fed around a single farming section in a single season.

# Why We Need a Separate Trade-Mark Bureau

## Growth in Use and Popularity That Demand a Greater Degree of Specialized Federal Oversight

By Chauncey P. Carter

IT is a fact little appreciated by those most interested that patents are granted by virtue of a specific constitutional provision authorizing Congress to secure "for limited times to authors and inventors the exclusive right to their respective writings and discoveries," while the right to exclusive use of a particular trade-mark is acquired by use, is unlimited in duration and is of interest to and may be registered by the Federal Government only if such use extends into interstate or foreign commerce and thus brings the mark into the purview of another constitutional provision giving Congress general authority over interstate and foreign commerce.

Patent rights and copyrights, therefore, are obtained by virtue of contracts between the inventors or authors and the Government wherein the former agree to disclose and do disclose their discoveries or writings in return for the grant of and protection in the exclusive right therein for a limited period after which they shall become public property.

The exclusive right to use a certain trade-mark to identify a certain kind of goods, on the other hand, is not granted by the Government in this country, but is acquired as a result of original use of such mark in connection with those goods just as a newsboy as a result of having been the first to do so, acquires an unwritten right to sell his papers on a certain corner, undisturbed by others. This is true not only in the United States, but also in England and in practically all countries where there is a "common law" consisting of court decisions as distinguished from those countries that are governed entirely by an approved code of laws and known as "code" countries. In most of the "code" countries, the right to the exclusive use of a particular trade-mark in connection with certain goods is not acquired by original use but must be obtained from the Government, which usually grants the same to the first applicant therefor, regardless of earlier use by another without such grant. In fact, it is a punishable offense in some "code" countries to use a trade-mark that has not been legally granted to the user.

Aside from these "code" countries, however, it will be seen that there is a fundamental difference between patent- and copy-rights on the one hand and trade-mark rights on the other hand, and even in the "code" countries this distinction is made: patent- and copy-rights are limited in duration, while trade-mark rights are unlimited in duration although they are often subject to annual taxes or renewals for revenue purposes and to avoid "sleeping on one's rights."

Notwithstanding this fundamental difference, it seemed wise to certain of our early legislators to place the registration of claims for rights to exclusive use of trade-marks in interstate and foreign commerce in the same hands as had been placed the grant of patents. It is not at all improbable that this was a result of a misapprehension in the minds of these early legislators that the rights were fundamentally similar. Indeed, the first law providing for the Federal registration of trade-marks was soon after its enactment declared unconstitutional, because it was not limited to marks used in interstate or foreign commerce and, therefore, had no place to hang its hat in the Constitution.

However that may be, the Federal registration of trade-marks has always been and is still with the Patent Office. The proposed breaking up of the Department of the Interior and the substitution for it of a Department of Public Works bids fair to become an accomplished fact in the not too distant future. be accompanied by a giving up of the Patent Office to the Department of Commerce as a sort of "swap" for the Bureau of Standards. It therefore seems proper to inquire whether this "swap" might not well be accompanied by a breaking up of the Patent Office into two parts, one to grant patents and the other to register claims to rights in trade-marks, labels and prints. Such an inquiry would seem to be justified in any case by the great increase in the number of trade-mark registrations that has taken place since this task was entrusted to the Patent Office and by a comparison between the numbers of patents and trade-mark certificates issued then and now.

In the Report of the Commissioner of Patents to Congress for the year ended December 31, 1918, it is stated that trade-mark certificates were first issued in 1870 when there were 121 of them as compared with 13,333 letters patent during the same year. As compared with this, the Report of the Commissioner of Patents to the Secretary of the Interior for the fiscal year ended June 30, 1919, indicates that in that fiscal year 3,766 trade-mark certificates were issued as against 37,259 Letters Patent. In other words, there has been an increase of over 3,000 per cent in the registration of trade-marks as compared with an increase of less than 200 per cent in letters patent. Moreover, while of the patents and trade-mark certificates issued in 1870, trade-mark certificates formed less than one per cent, in 1919 they formed approximately ten per cent. In the fiscal year 1915, the year in which the majority of applications filed prior to the outbreak of the war were finally acted upon, the trade-mark certificates issued compared even more favorably with patents than in 1919.

Despite these facts, and despite the great difference between the merchandizing field, in which advertising and selling depend so heavily upon trade-marks, and the engineering and industrial field, in which patent rights are of such great importance, it is a fact still that one man, the under-salaried Commissioner of Patents, has the last word this side of the courts in both patent and trade-mark matters. Hence, it is not at all unusual, but is rather to be expected, that the Commissioner in a single morning shall be called upon to decide whether there is any invention in a device for

## Ventilation of the Hudson River Tunnel

To the Editor of the SCIENTIFIC AMERICAN:

Readily admitting the necessity of vehicle tunnels under the Hudson River at Canal Street, there is the great importance of proper and ample ventilation without which the tunnels would be useless. The greater number of vehicles, probably 90 per cent, will be automobiles and motor trucks, exhaling poisonous gases. On this point the *Literary Digest* for August contains a very instructive article. It concludes with the warning that the contents of carbon monoxide (the most poisonous gas contained in the exhalations of motor vehicles) must not exceed the maximum of four parts in ten thousand parts of air. This conclusion has the endorsement of the United States Bureau of Mines, but the solution of the problem is left to the engineers of the Commission.

Although a novel problem, the principle of it is simple and easily understood. Fresh air enters through holes short distances apart from a fresh air duct, running the entire length of the tunnel. The amount of fresh air must be sufficient to dilute the poisonous gases at the required rate. Another duct, also running the entire length of the tunnel and also connecting with the tunnel through numerous holes, sucks up the contaminated air which is expelled through shafts at each end by mechanical blowers. The ventilation is thus crosswise to the tunnel and is a continuous operation that requires careful designing for its success.

Let us believe that the engineers of the Commission have thoroughly studied the problem, yet it is of such overwhelming importance that the details of that study should be published as proof thereof.

To mention only one point. The velocity of air and gases through the ducts will be very great. The friction along the walls of the duct and through the orifices will consume a great deal of power, which will increase rapidly as the walls of the ducts will become rough and incrustated from the dirt and dust in the air. The surfaces of the ducts will therefore require periodic inspection and cleaning similarly as chimneys require periodic cleaning from soot. To that end the height of the ducts should be sufficient for a man to walk through from end to end, 4,000 feet long. But the heights shown in the plans are only from one foot to four and one-half feet in the lower duct and from one foot to five feet in the upper duct. These heights are too low and would require continuous stooping of the workmen, which is both exhausting and tormenting in long, hot ducts. The upper grating seems hardly strong enough to bear the weight of any mechanical device or track for removing the dust.

Why is the fresh air duct placed at the bottom? Air coming up from the bottom will mix before being inhaled with the hot poisonous gases, which are expelled at the bottom of motor vehicles. If the cool, pure air is admitted at the top then it can be inhaled *before* it mixes with the foul hot gases at the bottom, which should be instantly sucked up.

For the ducts to be sufficiently large, the diameter of tunnel should be increased from 29 feet to 32 feet. That would also give more width for the roadway and sidewalk and contribute to greater safety of workmen and policemen employed in the tunnel.

No shortsighted economy should expose the users of the tunnel to poisoning by insufficient ventilation. On this point the details of operation cannot be too specific and should be published. The Commission by meeting this justified request at this time would invite public confidence just when it is most needed for the referendum vote, authorizing the bonds to be issued for this work, which not unjustly is regarded as a huge and costly experiment.

MECHANICAL ENGINEER.

## Wicker Weaving by Machine

To the Editor of the SCIENTIFIC AMERICAN:

Your issue of March 6th containing an article under the above title has been brought to the writer's attention. You have supplemented this article with editorial comments to the effect that the art of wicker weaving has been revolutionized. Evidently you are not aware of the fact that in spite of the invention you describe, wicker baby carriages are still woven exclusively by hand. In other words, the machine which you describe does not weave wicker but weaves an imitation of reed. Reed comes in strands about twenty feet long. The machine you describe feeds from a spool, and the writer has never yet seen a piece of material woven by this machine that was not made of fiber (twisted paper).

So the old art of weaving reed is hardly influenced by this machine. In order to be satisfied with a machine-woven carriage, the mother must be satisfied with a paper imitation of reed, and also must be satisfied with a monotonous sameness of design, as all of those scrolls, festoons and various designs which have been originated by reed workers to delight the eyes of the mother are impossible in the machine-woven carriage.

I have supplied these details for your information. At the same time I have had enough experience as an advertising man to realize that some press agent is entitled to congratulations on his success.

Elkhart, Ind. A. H. LORD.

## The Dendrograph

To the Editor of the SCIENTIFIC AMERICAN:

Referring to my description of the dendrograph in operation at the New York Botanical Garden published in the SCIENTIFIC AMERICAN for May 29, 1920, I will say that the article was written without due authorization.

Dr. D. T. MacDougal of the Carnegie Institution of Washington, the designer, placed this working model in the hands of Dr. A. B. Stout of the New York Botanical Garden for testing, with the privilege of describing the seasonal growth of the tree to which it was attached in the Journal of the Garden.

The Department of Botanical Research of the Carnegie Institution of Washington proposes to defer publication of a technical description of the instrument until it has been perfected by the aid of results secured from trials now being conducted by collaborators in various parts of the country. W. A. MURRILL.

# Twentieth Century Telegraphy

## The Big San Francisco Central Office, the Last Word in Equipment for Speed and Capacity

By Charles W. Geiger

WHAT is said to be the best equipped telegraph office in the world was recently placed in operation by the Western Union at San Francisco. Here all the innovations that experience has found to be desirable have been embodied and all features that experience has found to be undesirable have been eliminated. Standardization is now being carried to a point in the design and operation of these telegraph offices seldom seen in any industry.

The San Francisco office, which is the third largest in point of business transacted in the entire United States, handles approximately 2,500,000 messages per month, and due to the modern equipment and efficiency of operation, at least 2,400,000 of these messages are disposed of within ten minutes from the time they are received at the office.

The most striking feature of the new office, aside from the electrical and mechanical improvements, is the comprehensive system of automatic belt carriers which convey the telegrams to and from all parts of the great room. Thus, the greatest economy of time is effected in the handling of messages from the time they are received until they are on the wires.

This system consists of especially designed enclosed belt conveyors in front of every operator, along the center of the tables, conveying all messages entering the room to a central distributing center in a series of flumes.

Messages are received over the multiplex, the Morse, the telephone and by a pneumatic tube system leaving the city branch offices. The messages from these four sources are placed on the belt conveyors, which quickly deliver them to a slower moving belt in front of a line of young women, who sort them and place them on one of the four belt conveyors (according to their destination), to be conveyed to the transmitting operators. The maximum time in transit for messages around the room (which has an area of 10,000 sq. ft.) by means of these conveyors is 54 seconds with an average of 21 seconds.

A very ingenious method has been employed in carrying the conveyors across the main isle. This is done by double belts, both rising, and clasping the messages between them. This method is also employed in delivering the messages from the telephone room which is located on the floor below the main operating room.

The belt conveyors travel 250 feet per minute, each belt being driven by its individual motor. In order to guard against the delay of a message in passing over these conveyors, two men are employed whose only duty consists in constantly going around the room, stopping each belt in turn for a few seconds, lifting it up, looking under it to see that no message has slipped out of place, testing it to see that it runs freely and then starting it again. As a further precaution, mirrors have been arranged for inspecting the elevated sections of the belt system.

By means of the multiplex, messages are being exchanged between San Francisco and New York within ten minutes every day. The messages are almost literally geared to the inexorable time schedule from the moment they enter the operating room until they have found the proper wires and their transmission has been completed. It is not merely possible but frequent that a telegram is filed at a branch office at San Francisco and received in New York within fifteen minutes. Over shorter distances—say, one thousand miles—the time averages much less, and seven minutes is the average time required for clearing messages to Los Angeles.

It is hardly possible to describe the multiplex system briefly yet satisfactorily. It is based on the idea of an automatic distribution or apportionment of the use of a single wire at intervals, to eight automatic machines, each busily engaged in sending a different message.

The intervals are so rapid that each machine transmits its impulse over the circuit to a corresponding receiving machine, and its turn comes again after the cycle has been completed, in time for it to pick up and send the next impulse without any apparent hesitation. All the impulses are, of course, of equal

## Making Sure of the Concrete Batch

A FIELD equipment for testing crushed stone and sand and clay aggregates, compact, light and capable of withstanding a certain amount of rough usage, has been developed by the United States Bureau of Public Roads, and is proving of great value, both in the plant and in the field or wherever aggregates must be tested for control work in construction and especially in inspection of highway materials.

A factor which probably tends more than any other to discourage adequate control testing of highway materials is the time usually required to send samples to a laboratory for test purposes. Even under the most favorable conditions several days may elapse before a report can be secured, during which time the lot of material represented by the sample must be held. Aggregates always are subject to variations in size, due to inefficiency in plant screenings and other causes, and yet may be intended for use in construction requiring uniformly graded aggregates.

The field equipment consists of a set of interchangeable stone-screens, with screen plates having perforations, 3, 2½, 2, 1½, 1, ¾, ½, and ¼ inches in diameter; a set of interchangeable sand sieves of 10, 20, 30, 40, 50, 80, 100 and 200 mesh; a circular spring scale having a capacity of 30 pounds and sensitive to 0.1 of a pound; a straight spring balance having a capacity of 30 pounds and sensitive to 0.1 of a pound; a straight spring balance having a capacity of 200 grams and sensitive to 1 gram; a demountable cubic-foot box; an ordinary camera-folding tripod; a 250-cubic-centimeter graduate; a strip of screen wire about 22 inches in length and 5 inches high, and two canvas bags about 18 by 18 inches in size.

The interchangeable screen set consists of a number of perforated screen plates 8 inches in diameter, and two brass rings, one of which is provided with a narrow shoulder on the inside upon which a screen plate may be placed. The two rings are firmly clamped together so that the screen plate is held rigidly between them. This forms a screen of the same size and shape as the ordinary laboratory type.

The sand sieves are of the same general type as the screens, the various sieve plates fitting into the brass rings in the same manner. A sieve of any desired mesh may be made up by simply inserting the proper sieve plate in the lower ring and clamping it down by means of the upper ring.

The circular screen scale is supported by the tripod. The graduate is the only piece of glass in the outfit and is needed only when it is desired to make volumetric silt determinations. The circular loop of screen wire is used for making apparent specific gravity determinations of coarse aggregates. The strip is to increase the capacity of the screen, so that it may be used for weighing samples of sufficient size for this determination. It is rolled in the form of a loop and placed inside of the screen ring which in turn is suspended from the spring scales by means of three light wires.

The importance of the proper sampling of material in connection with the testing of aggregates cannot be over-emphasized. There are two points which must be borne in mind when sampling crushed stone and gravel aggregate. First, the sample must be representative of the entire quantity being examined; and second, it must be large enough so that the largest individual piece will in no case weigh more than 2 per cent of the weight of the entire sample.—By *R. Franklin Mundorff.*

## Binder Twine from Florida

WITH more than 200,000,000 pounds of binder twine being used annually to harvest wheat, oats, rye and barley in the United States, a company in Florida has begun the cultivation of sisal and henequen fibers as a source of home supply, the product heretofore being imported from Yucatan. The American farmer expends approximately $20,000,000 for the twine used in tying into bundles about 100,000,000 acres of small grain yearly.

Previous attempts to grow binder-twine fiber in the United States have been unsuccessful. The Florida enterprise, however, is assured a fruition of its plans by 1922. The first crop, necessitating the cultivation of 1,000 acres, was begun in 1917, five years being required to grow the first crop. Southern Florida is the only place in this country where climate and soil are such as to encourage growth of the fiber-producing plants.

Sisal is a tropical plant, the maintenance of which cannot be insured where the temperature falls to the freezing point at any time, 50 degrees being preferable. The lowest temperature in Yucatan is 48 degrees. Among the soil requisites are a porous limestone land, and adequate drainage. For profitable results it should be grown on a plantation of at least 1,000 acres. It is estimated that the first crop in Florida will require a capital of $100,000 before it is brought to fruition. This computation includes cost of machinery, land and the clearing of the virgin territory. The Florida enterprise has acquired several thousand acres of land, located in the southern portion of the Everglades, in Dale County.

This country is threatened with a shortage of binder twine due to the two-fold factor of a decreased price of the product with the resultant effect of a decreased acreage in Yucatan. There are ten companies in the United States making fiber from the Yucatan-grown plant, one concern alone using annually 40 carloads of fiber. There is no practical method whereby the twine can be recovered once it is used in tying the bundles of grain, a fresh supply being demanded each harvesting season. It is a low-priced crop and cannot be grown on high-priced land, the yield of sisal not exceeding $100 an acre. American hemp as a substitute is too valuable and is not otherwise altogether satisfactory.

About 2½ pounds of twine is used for each acre of grain, with the exception of corn, which requirement is in excess of these figures.—By *S. R. Winters.*

## Putting the Street Lamps into Niches

THE huge Kensico Dam at Valhalla, N. Y., which forms part of the Catskill water supply system of New York City, is crowned by a broad roadway which is used by pedestrians and vehicular traffic alike in crossing the broad valley at that point. Hence one of the problems confronting the designer of the dam was the installation of some suitable lighting system for the roadway. At first the usual lamp post idea was suggested, of course using suitable lamp posts in keeping with the general appearance of the masonry construction. But on second thought it was decided that lamp posts of any sort would detract from the appearance of the dam, with its impressive flat top unmarred by any projections.

The final system of illumination adopted and installed on the Kensico Dam roadway consists of a large number of niches in the parapet walls, each containing a high power nitrogen-filled incandescent lamp behind a sheet of prismatic glass. A near view of one of these lighting units is shown in the accompanying illustration, which depicts how the prismatic glass and lamp are protected by a grillwork. The unit may be opened for inspection, cleaning, and the renewal of the bulb by opening the padlock. These units, placed at intervals of about fifteen feet, first on one side and then on the other side of the roadway, spread out their rays so that they virtually overlap, thus forming one sheet of light from one end to the other of the dam roadway. The effect is most pleasing, since the light is kept near the surface where it is needed, unlike the usual system of lighting.

# Taking on Oil a Mile at Sea

## How Vessels Receive Fuel at Mexican Gulf Ports Without Approaching the Docks

By James Anderson

AMERICAN efficiency has made oil one of the first requisites in the commercial life of our times. American initiative has uncovered many secret deposits of the fluid. American energy has brought it to the seaboard. Now as a fitting culmination American skill has devised a novel and most up-to-date system of loading it on ships a mile or more out at sea.

To those accustomed to think that the only way a vessel can be expeditiously loaded is to run her into some port, tie her up to a dock and then put a crew of stevedores to work placing the cargo snugly on board, the idea of loading a vessel well out to sea seems an impossibility. But that is just what is being done daily in Port Lobos and at several other points along the Mexican coast by a number of different American oil companies.

**Beach end of the pipe line, completed and ready to start operations**

Port Lobos, it will be recalled, came into the immediate limelight wherever oil was sold in the latter part of 1919. During the month of November of that year this port, the centre of that bleak stretch of windblown tropic shore that stretches from the mouth of the Panuco River at Tampico across some forty miles of coastal plain to the Gulf of Mexico, rolled up a monthly total of 2,000,000 barrels of oil. But not satisfied with this fact, Port Lobos is now seeking new laurels because it is there that the most satisfactory system of loading tankers that has ever been devised is being carried on.

The big ships stand a mile out in the open roadstead, pick up the buoyed end of a water-proofed pipe line, and through it suck in the oil until their bunkers are filled.

Along this stretch, occupied formerly by only pelicans and airgrettes, but now by wireless stations and those who produce the black liquid wealth from nature's storage tanks, powerful pumping stations dot the landscape. They bring oil from the wells far inland to store it in great tank farms from where they pump it through submarine feeding lines to tankers flying the flags of all nations. The work of loading these vessels through these submarine feeding pipes constitutes one of the most interesting experiments of the generation. While the process is practically new it has already proved a godsend to vessels which previously found it necessary to load with oil under the greatest difficulties, in ports that did not offer the proper facilities for docking and where there was the usual Mexican delay in awaiting pilots, custom officials, immigration inspectors, or doctors. Furthermore in following the new process of loading one has no harbor dues to pay, nor is there any danger of damaging small floating craft or wharfage construction.

*TO those who are accustomed to think that the only way to load a vessel is to tie her up to a dock in some port and put a crew of stevedores to work, such a thing as loading ships while at sea would seem to be impossible, yet it is now being done daily and has proved the most satisfactory system of loading tankers yet devised. It is carried on by a number of different American oil companies in Port Lobos and at other points on the coast of the Gulf of Mexico. Just how it is accomplished and how successful it has already been proved to be is told in this story.*—THE EDITOR.

As a first preliminary to the process of loading a vessel at sea with oil, two lines are laid on the ground for more than a mile back from shore connecting the pumping station with what are known as the sea lines. The sea-going pipes are painted with crude petroleum and then wrapped tightly in burlap. They then receive another heavy coating of crude oil, are once more wrapped in burlap, and again painted. All this is to assist the pipe in resisting the corrosion by salt water when it is under the sea. As an additional protection river clamps of wood about four feet in length are placed about every connection to prevent attack by the water at the joining. When ready the entire pipe is lifted to trucks on a narrow gage track in a straight line back from the shore. On the end that is to project into the sea a connection of 120 feet of 8-inch flexible rubber hose, heavily reinforced, carrying a securely closed nipple, is attached.

A sand sled, used to prevent the pipe from burying itself while being pulled to sea, is next placed under the front end of the line. A gasoline drum is tied on the top of the sled to keep the end of the line visible while being drawn out. Guiding blocks are then placed at either side of the line at its ocean end. Next a favorable day is awaited, when one of the tankers especially prepared for the purpose is moved into position to pull the line seaward.

Following these preparations the line is fastened to the tanker by means of a heavy cable. Then when all is in readiness the ship, light from lack of cargo, comes in as close as possible to the shore and then steers a straight course away from the beach to fixed mooring berths. The line moves seaward at the rate of about four miles an hour. As the trucks on which it is conveyed come to the end of the track they roll off on to tank plates and are removed from under the sea line.

Once the pipe lines begin to move seaward little time is lost in going ahead. In fact, from that point until the completion of the whole operation only about twenty minutes elapse. The operation must keep moving and once it gets started cannot be stopped, as the line would break of its own weight were an attempt made to pull it further after it had settled to the floor of the Gulf. Naturally it takes a great deal of skill and careful handling to pull one of these lines to sea successfully. Much of the credit for the success with which the operation is carried out should go to the managers.

The line laid to sea, connections are placed from it to the storage tanks, and the hose connection on the ocean end of the line is "marked" by means of a wooden float which is capable of carrying the weight of the hose.

Wherever the loading at sea takes place there you will see in readiness at all times numerous motor surf-boats. Each one is directed by what is called the mooring master. When a ship is announced, or is sighted, this surf boat is sent out to meet it. The mooring master boards the ship and takes full charge.

When the ship has been moored and

Two views of the wireless outfit installed on the Regatta Committee barge during the recent Gold Cup Regatta on the Detroit River

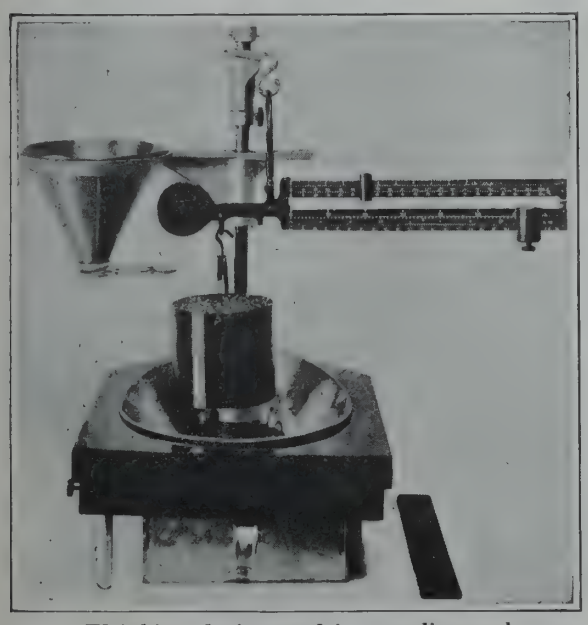
## Using Wireless to Catch the Newspaper Edition

IN order to catch a certain edition, necessitating the rapid transmission of the results of the races, a Detroit newspaper made good use of wireless telegraphy during the Gold Cup Regatta, held recently on the Detroit River.

A short-range wireless transmitter and a conventional receiving set were installed aboard the Regatta Committee barge, as shown in the two accompanying views. A young radio amateur of Detroit handled the press dispatches aboard the barge and transmitted them some eight miles to the newspaper office in Detroit. Thus the results of the races were immediately conveyed to the editorial rooms, whereas, upward of an hour would have been required by means of a fast boat and the information could not be issued in the desired edition.

## Simplifying the Fire-Fighters' Job

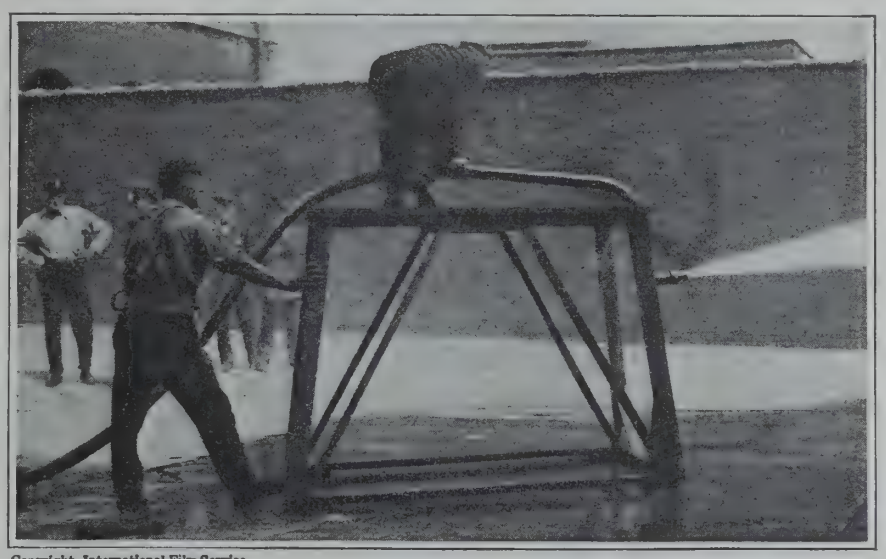
THE Chicago Fire Department has recently introduced a new form of nozzle for fighting flames from roofs and other elevated points, from which the streams of water are thrown more or less horizontally. The new nozzle, instead of being straight as is the usual equipment, has two bends as shown in the accompanying illustration. These bends are made so that the nozzle may be rested on the parapet or coping of a roof, balcony railing, fire escape, window ledge, or any other suitable object, thus taking the weight and strain off the fireman's hands. The nozzle then becomes a hinged nozzle, so to speak, which can be aimed in any direction and held in the desired position with little or no effort. By means of this nozzle several men are freed from nozzle duty and can devote their efforts in other directions.



Weighing device used in sampling and grading grain

## Speeding Up the Grading of Grain

TO expedite the efficient and accurate grading of wheat and allied small grains on the central markets, an ingenious device is used in measuring and weighing the different materials. Under normal conditions, it is difficult to fill a measure with exactly the same amount of grain from each sample and on this account a special appliance has been provided which delivers the grain by gravity into the measure that is standardized and used in keeping tab on the bulk and volume of the various samples.



Copyright, International Film Service

This new nozzle, which may be rested on ledges and railings, enables one fireman to handle a powerful stream of water

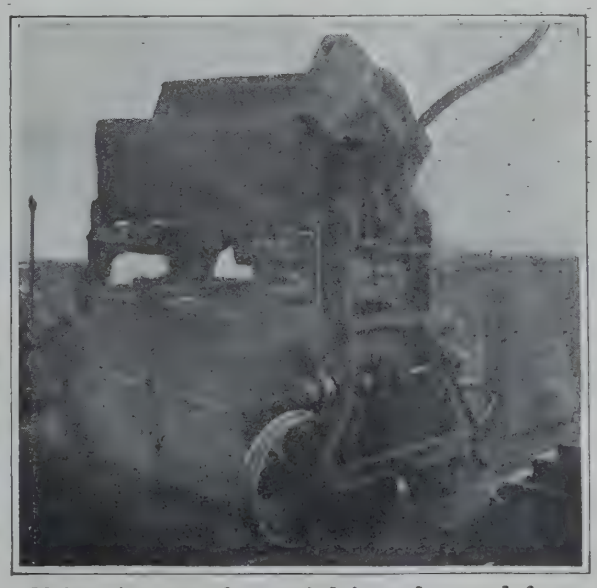
A conical reservoir with a slide mouth is used for the initial reception of the grain sample to be weighed. When full this deposit is rotated until it is directly over a one quart measure which is attached to a compensating scale which is regulated so that it weighs only the grain. The slide at the bottom of the reservoir is then opened and the grain flows evenly and uniformly under the force of gravity into the measure. When it is full, the surface is struck properly and the amount of grain then remaining in the measure is weighed accurately on the scale which is designed to weigh in terms of pounds per bushel. It is thus easily possible to ascertain the exact amount of grain in each sample and whether it is under standard in weight due to the presence of shriveled and undersize grain; and accidental errors due to irregularity in packing the quart measure are brought down to a negligible minimum.

## Conveying Molten Iron to the Molds

A NEW device for handling molten iron in a gray iron foundry has been invented by a Cleveland foundryman. It is in use in his own foundry and is a labor saving machine as well as a very efficient one. The device, as illustrated, consists essentially of a cylindrical ladle mounted on trunnions in such a way that the iron may be discharged through nozzles which become submerged when the ladle is rotated. The metal flows from the nozzles into two semi-circular guide troughs which convey it to the runners leading to the mold. The entire apparatus is carried on a frame mounted on wheels which render it readily portable.

The ends of the pouring basin are constructed of cast iron with a segment removed. The sides are made of heavy boiler plate perforated and securely riveted to the end castings. The inside of the basin is lined with one course of 1-inch fire brick. The basin is supported by trunnions which rest in sliding shoulders. The shoulders move in vertical guideways and are raised or lowered by an adjusting screw which is operated by a hand wheel. By this arrangement, the level of the pouring basin may be maintained and any depression in the track will have no effect on the iron level if the trunnion shoulders are adjusted. The rotary motion of the basin is controlled by a lever securely bolted to the trunnion flange on the operator's side of the machine. An extension arm carrying a counterweight is provided; this offsets danger of the basin's turning over of its own accord while the iron is being poured into it from the crane ladle. Two cast-iron guide troughs rest upon the side frames and may be lifted off when it becomes necessary to reline them with clay. A one-inch opening through which the iron flows to the sprues is provided in the bottom of each trough. The distance from the floor to the bottom of the basin is 3 feet 2 inches.

The entire device is supported by three flanged wheels—two on the operator's side and one on the helper's side—which run on rails spaced 4½ feet apart and permit the machine to be moved in a straight course over the molds. When several rows of molds are to be poured the machine may either be moved from one row to another by a traveling crane, or run to the end of the track and wheeled to the adjacent row of molds, for which purpose a lifting device is provided. It is said that two machines will take care of the output of a cupola which melts between 18 and 20 tons per hour and that only four men are required. Bull ladles required 14 men.



Molten iron can be carried in and poured from this straddle truck

# The Heavens in October, 1920

## The Latest Nova, and the Present State of Knowledge and Speculation About These Strange Stars

By Professor Henry Norris Russell, Ph.D.

THE principal astronomical event of the past month —announced just too late to find mention in the preceding of these articles—was the appearance of a bright Nova or temporary star in the constellation Cygnus. This object was discovered by Durning, a prominent English observer of meteors and planetary detail—on August 21st, the day after last month's "Heavens" had to leave the author's hands—as a conspicuous naked eye star, north of Delta Cygni. During the next day it increased somewhat in brightness, reaching the magnitude 1.9, which has been surpassed by only two Novae in the past century, Nova Persei of 1901 and Nova Aquilae of 1918. It then began to fade rapidly, and by September 1st was no longer conspicuous, though easily visible when one knew where to look for it. At the date of writing it is barely visible on a clear dark night without telescopic aid.

The Harvard photographic plates show that the star was exceedingly faint, if not invisible, a week before its discovery. The rise to maximum was slower than is usual with Novae, and the initial stages of the fall rather more rapid than ordinarily. Apart from this, the outburst appears to be typical. The spectrum, while the star was increasing in brightness, showed, as in other cases, dark lines only, and was generally similar to that of Altair (A5 in the Harvard classification). As the light passed to maximum the characteristic wide bright bands, with dark lines on the side toward the violet, made their appearance. Like other Novae, too, the star is in the Milky Way and not far from its central line.

How much additional information this star will give us regarding the nature of the processes which produced the tremendous outburst it is too early to say, but meanwhile, other information bearing on the problem has come in from different directions. A curious variable star T Pyxidis was discovered seven years ago by Miss Leavitt, on Harvard photographs. Usually it is very faint, of about the 14th magnitude; but in May, 1890, it rose in a few weeks almost to the 7th, and again in May, 1902, it repeated the change, falling off once more in brightness very much after the fashion of a "new star." No photographs of its spectrum were obtained during either of these maxima, which it is interesting to note took place eleven and twenty-three years before the discovery of the variability. But in 1920 the star blazed up a third time, and the spectrum was photographed and found to be of the characteristic Nova type. It is in 9h. 0m. R. A. and 32° south declination, close to the Milky Way; and on the basis of the observations of 1920 alone, the star would undoubtedly have been classified as a Nova. The fact that it has been known to brighten up twice before appears to be no reason why we should change our opinion. Most Novae, it is true, have exhibited but one great maximum. But several, including the bright Nova Aurigae of 1892, and two fainter ones recently observed in Ophiuchus, have fallen off in light, sometimes greatly, and then come up again, though before the earlier outbreak was fully spent.

### A Monumental Variable

But if we grant T Pyxidis to be a Nova, what shall we say about the still more remarkable star Eta Carinae? This famous southern variable (in a nebulous region in the heart of the galaxy) was of the fourth magnitude when first noticed by Halley in 1677. It appears to have been a fairly conspicuous naked-eye object till about 1810, when it rose in brightness. For almost twenty-five years, from 1826 to 1850, it was above the first magnitude, and in 1843 it exceeded Canopus in brilliancy, and was surpassed only by Sirius. After 1850 it faded steadily, and since 1865 it has been fainter than the seventh magnitude, with small fluctuations. It is now of magnitude 8.3, and not more than 1/4000 as bright as at its maximum. Its spectrum during the past thirty years has consisted mainly of bright lines, with a continuous background crossed by dark lines, which, according to Miss Cannon, disappeared about 1895, coincidently with a diminution of the star's brightness by about one-half. This spectrum is strongly reminiscent of that of Novae in certain of their later stages. What the star's light would have revealed in the years of its great brightness we, alas, will never know; for in those days the spectroscope was unknown.

There appears therefore to be a series of objects strikingly similar in spectrum, and all characterized by great and non-periodic fluctuations in brightness. At one end stand the typical Novae, which rise to maximum in a day or two, and fade away in a few years, losing by far the greater part of their light within the first few weeks. At the other end of the scale is Eta Carinae, whose changes have occupied not days, but years.

### What Does It All Mean?

It would seem probable, though by no means certain that similar causes are at work in all these variables. What happens during the outbursts, however, is still obscure. We recorded a few months ago the evidence that makes it probable that, in the typical Novae at least, a shell of incandescent gas is actually thrown out from the star at enormous speed; but we can only guess, rather wildly, what the forces behind such explosions can be like.

Certain things, however, are evident. Whatever the catastrophe may be, it does not destroy the star, nor even use up any great portion of it—for T Pyxidis has gone through the process three times in the last thirty years, and is still there. Moreover it must be a standard process, in the sense that it occurs with fair frequency somewhere in the stellar universe, probably as often as once a year. This disposes once for all of the idea that the Novae are produced by collisions between two stars; for it can easily be shown that, even among the billions of stars that probably exist, no two should collide except at average intervals of many millions of years. The hypothesis of a collision between a star and a nebula, or possibly a small body of planetary dimensions, meets this difficulty; but it is hard to see how such a collision could be the direct cause of the expulsion of a shell of gas at such enormous speed.

Perhaps a solution may be found in the idea—supported now by evidence from many quarters—that the stars contain some vast store of energy, of little known nature, which they are gradually transforming into heat and radiating away. Under ordinary circumstances, it is probable that the rate of generation of heat is automatically regulated to balance the loss by radiation. But it is quite conceivable that some sudden disturbance in the substance of the star, near the surface, might cause an abrupt liberation of a great amount of energy, sufficient to heat the surface excessively, and drive the hot material off into infinite space, in much the form of such a shell of gas as seems to have been observed in the case of Nova Aquilae. A collision with a swarm of meteors might easily provide the necessary initial shock—this acting as the detonator, rather than as the bursting charge. If a star has run into one such cloud, there may be others near by, and the repeated outbreakings of Nova Aurigae, and even of T Pyxidis, may thus be simply explained. Such a long-continued outpouring of energy as took place from Eta Carinae is harder to understand. But with the rapid advance of our knowledge of the properties of the stars on the one hand, and of the very nuclei of atoms on the other, we may, perhaps before very many years have passed, find ourselves nearer a solution of the problem.

NIGHT SKY: OCTOBER AND NOVEMBER

### The Heavens

The finest parts of the evening sky are now in the east and west, along the line of the Milky Way, which extends over our heads in a vast arch. Beginning at the west, we find Aquila low down, and Lyra a little higher and to the right. Above the latter is Cygnus—no longer marked by the brilliant new star, which has faded from view to the unaided eye. Then come Cepheus and Cassiopeia, almost overhead, followed by Perseus, high in the east, with Auriga below, and Taurus to the right of the latter. Gemini and Orion are rising, below Auriga and Taurus, but are not yet fully seen.

The northern and southern skies are dull in comparison. The Great Bear is far down on the horizon, and Draco and Ursa Minor are below the pole and to the left of it. Opposite these, across the Milky Way, are Pegasus and Andromeda, close to the zenith. South of this, and extending far to the east and west, is one of the poorest regions of the heavens, which surrounds the southern pole of the Milky Way. The only stars within it which are really conspicuous in our latitudes are Fomalhaut, in the Southern Fish, and Beta Ceti, farther to the eastward. Aquarius, Capricornus and Eridanus, which occupy the remainder of the southern sky, do not boast among them all a single star as bright as the second magnitude.

This is true, at least, for observers in our latitude. Farther south, in tropical countries, the rather conspicuous southern constellations of the Crane and the Phoenix become prominent, and the first magnitude star Achernan (Alpha Eridani) comes into sight.

### The Planets

Mercury is an evening star all the month, and is best seen about the time of his elongation, or greatest apparent distance from the sun, on the 25th. He is then 24 degrees from the sun, but so far south that he sets a little before 6 P. M. (standard time) and is rather hard to see. Venus is an evening star, and is gradually drawing away from the sun; but she, too, is far south, so that even at the end of the month she remains in sight only until 6:25 P. M.

Mars likewise is an evening star, but farther east, and he therefore remains in sight longer—until about 8:30 in the middle of the month. Jupiter is a morning star, rising at 3:25 A. M. on the 1st and at 1:55 on the 31st. Saturn is about ten degrees farther east,

**The start of displacement boats. Won by "Rainbow" with an average speed of 39.48 miles per hour**

## The Fastest Boat in the World

THAT amazing little craft, "Miss America," after winnning the Harmsworth Cup in British waters was brought back to America and entered as a contestant in the Gold Cup Regatta, which was held on the Detroit River. She not only won the one-mile championship trials for the Lake George trophy, but secured several other trophies. The contesting boats had to make six one-mile dashes over the mile course. In one trial, which had to be thrown out because only three of the six watches got her time, "Miss America" was clocked at the rate of 78.94 miles an hour. The average time for the six dashes credited the little boat with an official speed of 76.73 miles an hour. Her best official run was made at a speed of 77.85 miles an hour. The performance was very consistent, as will be seen from the following timings: First mile, 47.06 seconds; second mile, 46.2 seconds; third mile, 47.1 seconds; fourth mile, 46.6 seconds; fifth mile, 47.3 seconds; sixth mile, 46.6 seconds.

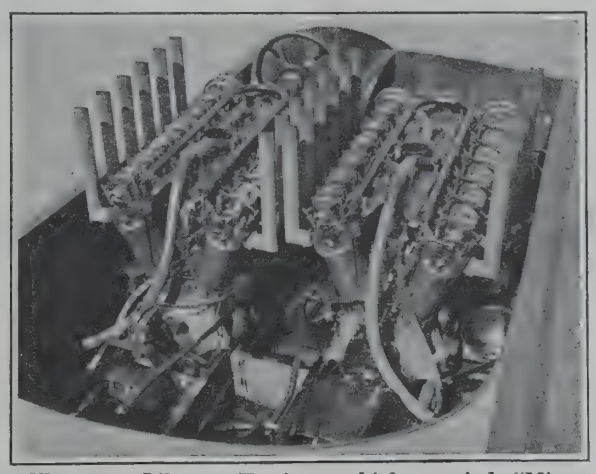
Only one other hydroplane competed in these trials, the "Miss New Orleans," which made an average speed of 58.35 miles per hour, with a fastest lap of an even sixty miles. We show an illustration of the start of displacement boats with stock marine motors for the Fisher trophy. It was won by the "Rainbow," of the Royal Hamilton Yacht Club, with an average speed of 39.48 miles an hour, and a maximum speed of 40.75 miles. The "Miss America" is a diminutive craft with an enormous horsepower for her weight. She has a single step, and is driven by two Liberty motors with a combined horsepower of 800.

## Artificial Glaciers for Irrigating Dry Land

AN ingenious method for securing a supply of water for their parched fields during the hot season is practised by the mountaineers living upon the slopes of the Karakorum, the great chain of mountains at the northwest extremity of the Himalayas, and is thus described by Mr. Dainelli, a member of the Italian Alpine Club, in the Bulletin of that organization:

The inhabitants choose points as high as possible in lateral valleys which furnish but little water supply in the summer to the principal valley which it is desired to irrigate. Such spots are chosen as are shut in with steep banks so as to receive little or no sun. During the hot season these valleys are filled with successive layers of straw saturated with water and if possible with dry pine needles and even charcoal. Before the first snow fall the bed thus prepared is covered with pebbles. When the heavy snowfalls of the season are at an end the top layer of snow is covered with straw and then with earth.

**"Miss America," running her fastest mile at an official speed of 77.85 miles per hour**



**The two Liberty Engines which carried "Miss America" to victory**

## Daring Voyage of a Wrecked Ship

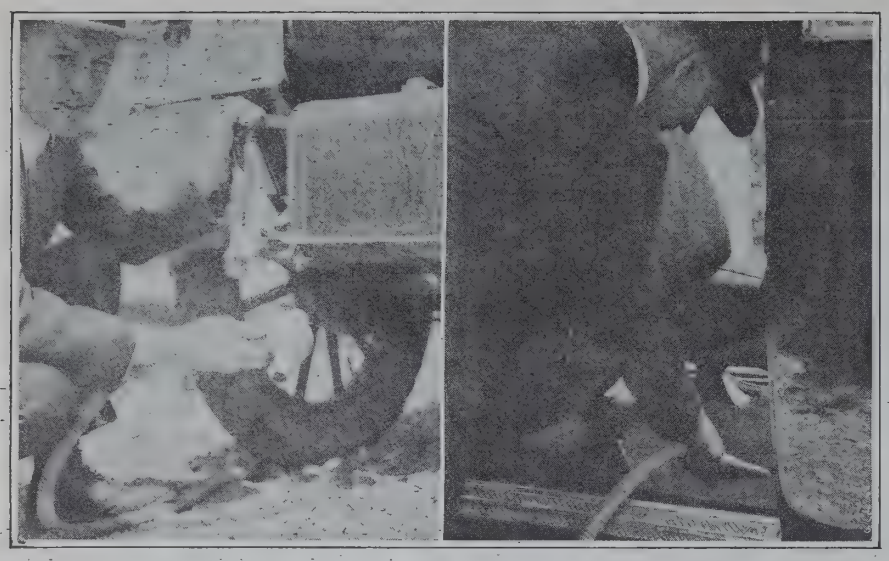
THE United States ship "Ophir" is one of the Dutch merchantmen which were commandeered by the United States. She was employed in carrying supplies to and from the seat of war, and, as fate would have it, on her last trip, she carried some ammunition which caused no end of trouble; for while she was at Gibraltar the ammunition caught fire and sent the ship to the bottom. She lay there for four months, and was subsequently raised by our Navy Department and brought back to the United States.

What the fire did to the ship will be understood from the accompanying photographs. The woodwork, it will be noted, was entirely burned away, leaving only the open steel framework of the boat and superstructure deck. Moreover, the ammunition in the hold exploded under the fierce heat, and the shell fragments passed through the steel deck above, giving it the proverbial pepper-box appearance. The ship was in bad shape, for her hold was open to the sea. Nevertheless, it was believed that good seamanship was capable of bringing her from Gibraltar to Norfolk, where it was decided to carry out repairs. As it turned out the "Ophir" during her trip ran into one of the worst storms that the Navy men who brought her over had ever encountered; nevertheless, although she rode with her decks open and with the seas washing through into the hold, she was kept afloat by running the pumps continually throughout the voyage; and though it is estimated that the gale blew at times with a velocity of one hundred miles an hour, the "Ophir" did not send out any S. O. S. call. The courage and skill required under these extremely trying circumstances will be understood, when it is remembered that the photographs herewith shown were taken after the ship arrived at Norfolk.

## Selenium

WHILE several fields of usefulness have been found for the element selenium, it may still be produced in far greater quantity than present demands would justify. Consequently its utilization offers an interesting field for research. Professor Victor Lenher has been giving particular attention to the chemistry of selenium oxychloride and has found it to be a solvent with remarkable properties.

***Left:*** **U. S. S. "Ophir," burned and sunk at Gibraltar, was brought to Norfolk, Va., in the condition shown, weathering some heavy storms.** ***Right:*** **The between-decks, showing how exploding shell fragments tore through the steel deck, until it looked like the proverbial sieve**



A member which fastens on to the exhaust of the engine, creates the vacuum for the nozzle used in cleaning the automobile

## A Vacuum Cleaner for the Motor Car

THE last word in automobile accessories is the vacuum cleaner which is operated by the exhaust of the engine. This device, which is shown in the accompanying illustrations, consists of a member which is placed on the exhaust of the engine and which creates the vacuum, a long flexible tube, and a suitable nozzle. By running the engine at slow speed a sufficient vacuum is obtained to clean the automobile in a far more thorough manner than can be done with the conventional methods.

## Getting Away from the Conventional Rudder

AGAIN we have with us the two-part rudder, which permits a power boat to be reversed without altering the speed or direction of the engine. Similar devices have been described in these columns as far back as two years ago, when a similar scheme was introduced by H. O. Wetendarp of Boston, Mass., with excellent results in the case of a small motor boat.

This time it is a British inventor who comes forth with a two-piece rudder. His device consists of two curved deflectors, each deflector of about the same area as the usual rudder. The rudder post consists of a steel rod attached to one deflector, and a steel tube fitting over the steel rod, which is attached to the other deflector. Two steering wheels are provided, one operating the left blade and the other the right blade. This device is more than a rudder; it is a brake as well. For instance, when the two deflectors are closed and placed directly behind the propeller, the engine may be going at full speed or less, and yet the boat slows down, and then begins to move backward. By gradually opening the deflectors the reversing action becomes weaker and weaker as the propeller has a tendency to propel the boat forward. Swinging both deflectors to one side or the other causes the boat to respond in the same manner as if a rudder were employed. Full speed ahead is attained when the deflectors are open and parallel to each other.

New form of rudder installed on a small motor boat

## Expediting the Stamping of Letters on Soft Metals

FOR stamping letters, figures or any characters on metals or other substances while in a soft state, an ingenious marking machine has been placed on the market by a Chicago manufacturer. This machine consists of a frame with a fixed base, said frame carrying a heavy shaft on which two large disks are pivoted. These disks house between their inner walls a number of small disks of tool steel. The disks rotate on their own axes while the characters on their peripheries are used for obtaining the impressions desired.

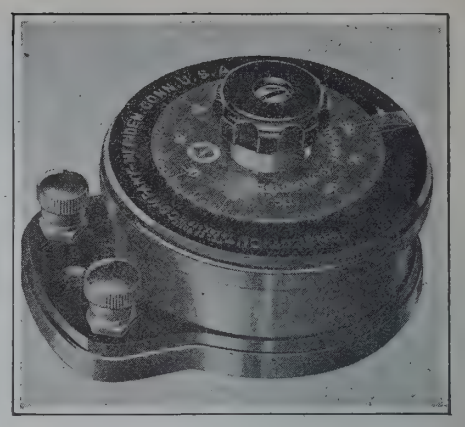
The device has an automatic feed and each size of character has a fixed feed. Cams and a multiple rack shaft action cause the feed, and the impression is obtained by means of a crank shaft connected with a handle and connecting rod. This mechanism is so constructed that the characters will not break if any part of the metal should develop resistance. The adjustment for obtaining impressions on various sizes of objects or work being done, is controlled by turning the ball handle in either direction and following the gage on the side of the device until the desired impression is reached.

The machine illustrated is for use with hand power, but it may be operated by machine power. A full alphabet and the numerals from 1 to 0 in 1-16, 1-8, 3-16, and 1-4 inch sizes are furnished with the device.

## Something New in Electrical Variable Condensers

IN an effort to produce a simpler and more compact construction, an electrical instrument manufacturer has recently introduced the variable condenser shown in the accompanying illustration. Also it is claimed for this new condenser that its results are more constant and that finer adjustments are possible.

Compared with the usual variable condensers used in fine laboratory work and more so in radio communication, with their assemblies of finely separated plates which work in and out of each other without touching, the new condenser is remarkably simple. It consists merely of a fixed plate at the top and a movable plate at the bottom. The bottom plate can be actuated up or down by means of a fine screw thread attached to a suitable handle, thus decreasing or increasing the distance between plates. A spring placed upon the screw operates to open the plates when the nut is unscrewed on the shaft. A mica washer separates the two plates, so that they cannot come into contact with each other. The variation of capacity is obtained by merely screwing the nut upward and downward on the screw shaft, and the thread is selected so that the entire range of capacity is secured by one turn of the nut.



General appearance of the new variable condenser introduced for laboratory and radio work

## Scientific Investigation of Artificial Wool

WIDESPREAD interest having been taken in a new artificial wool, an exhaustive investigation into the properties and merits of the fiber has been made by Prof. Eber Midgley, head of the department of textile industries of the Bradford Technical College, whose main conclusions may be summarized as follows:

Professor Midgley has demonstrated by machinery tests that the artificial wool is unsuitable for use in the spinning of yarn on the worsted principle, though he admits that there may be some scope for the employment of the fiber in the woolen industry. It is impossible, however, he adds, to produce from artificial wool a fabric comparable with one composed of pure wool.

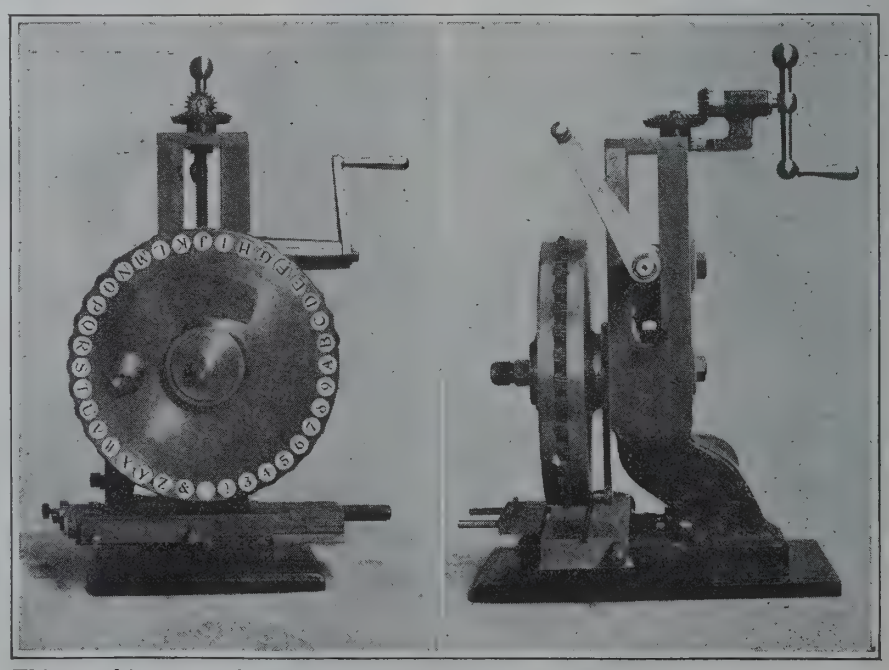
When compared with a low quality of worsted wool, artificial wool indicated a decided lack of uniformity in diameter, strength, and elasticity, factors which are essential in the manufacture of worsted yarns.

In order to provide the artificial wool with most favorable treatment, the Continental systems of combing and drawing were employed. The result of the combing was 39 per cent top and 61 per cent noil, as compared with 82 per cent top and 18 per cent noil in the case of pure wool; while the result of the drawing, blending it with pure wool, was an uneven yarn.

By suitable manipulation a yarn can be spun on the woolen principle entirely from artificial wool, but the type of yarn will be thick and limited to use as weft. Developments can be anticipated on the lines of mixing the material with wool and remanufactured wool for the purely woolen trade; but so long as the present supplies of cotton and wool are maintained, artificial wool and many other substitutes cannot, in Professor Midgley's opinion, in any way affect either the cotton or the wool industries.

## Recent Patent Decisions

**Wireless Telegraphy.** — This is a suit involving the Fleming patent so far as concerned a detector for radio waves. Eight or nine years after the date of this patent, several experts in the radio art, while using these devices as radio wave detectors, observed that the detectors possessed the function of oscillating, or, in other words, of generating radio waves. This was an extraordinary additional property or function of the so-called incandescent lamp detector, of which Fleming had no knowledge. A claim of the patent provides for the combination of a vacuous vessel, two conductors adjacent to but not touching each other in the vessel, means for heating one of the conductors, and a circuit outside the vessel connecting the two conductors. While the claim covers broadly the device when used in the radio art, yet when read with the context of the specification, it is plain that Fleming's disclosure was addressed to the use of the instrumentality as a detector only. It is a principle of the patent law that a patentee is entitled to all the benefits of his invention, whether or not known to or foreseen by him. Therefore the patent is held infringed by a generating device. Judgment for plaintiff.—*Marconi. Wireless Tel. Co. v. DeForrest Radio & Tel. Co. U. S. D. C. of N. Y.*



This machine puts the stamping of lettering on soft metal in the same class as the cutting of packing room stencils

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

## Pertaining to Apparel

BRASSIERE HOOK.—G. T. COLTER, 419 W. 119th St., New York, N. Y. The invention relates particularly to a hook used with corset covers or brassieres. An object is the provision of an arrangement which may be used for properly holding a brassiere in position in connection with a front or back laced corset. Another object is to provide a hook or fastening means which is adapted to be hooked into or interlocked with the front of a corset without producing an undesirable lump or gathering of material, and also without danger of becoming dislodged when in use.

HOSE SUPPORTER.—A. D. PERALTA, c/o Young & Glen, 68 Broad St., New York, N. Y. The invention relates to garment supporters and is more particularly adapted to hose or socks. The general object is to provide a support which can be conveniently applied and detached, the support preventing suspender ends in looped form through which a portion of the hose may be passed, together with a slide into which a portion of the hose may be drawn and then securely clamped.

SNAP FASTENER.—W. H. LAMMERS, 2495 8th Ave., New York, N. Y. The object of the invention is to provide a snap fastener for garments as distinguished from hooks and eyes, buttons, and the like. Among the objects is to provide a fastener of minimum thickness when applied to the garment. More specifically the fastener comprises head and socket members adapted to be attached directly in the usual manner, but are not easily separable directly, the separator being effected by a sliding movement.

## Pertaining to Aviation

AIRPLANE.—H. C. NEAL, Philadelphia, Mississippi. An object of the invention is to provide an airplane embodying features of construction, whereby the airplane acts as a parachute in the event that the engine stops so that the aviator may land with safety. A

A PERSPECTIVE VIEW OF AN AIRPLANE AS INVENTED

further object is to provide mechanism capable of adjustment and operation while the machine is in motion, to enable the airplane to remain in substantially one position, to facilitate observations, and to remain in a normal position when standing on the ground.

WING.—H. M. WOLFE, 75 Vesey St., New York, N. Y. The invention relates to aeroplanes and other aerial machines; its object is to provide a wing more especially designed for use on a fighting air craft, and not liable to collapse when subjected to heavy strains or when riddled with bullets. Another object is to render the wing exceedingly durable and capable to readily withstand heavy wind pressure.

## Electrical Devices

ELECTRICAL TOY GUN.—T. H. HALLINAN, 212 Madison Ave., Paterson, N. J. An interesting toy is provided by this invention, which permits of rapidly firing a number of shots from the same gun, using electro-magnetism for the propulsive power. The operation of this small, rapid-fire gun is controlled electrically and it may be manipulated by a very small child without danger to the operator or to any surrounding objects.

FLASH LIGHT.—J. VINCE, 429 78th St., Brooklyn, N. Y. The invention relates to portable electric lights of the class including a battery and lamp, the one movable relatively to the other, a shell inclosing the battery and supporting the lamp having means to connect the same in circuit at the front of the battery, together with means tending to separate the lamp and battery to break the circuit at the front of the battery.

ADJUSTABLE ELECTRIC CONTACT.—F. H. LORKING, 10 Davenport Terrace, Wayville, South Australia, Australia. This invention comprises a contact for electrical work which grips an adjusting nut and even when the wire holding nuts are slackened off for adjustment or other purposes remains locked to the insulating lock and is capable of a micrometer adjustment. It is especially suitable for circuit breakers, polechangers and circuit controllers used in signal engineering or other work where comparatively light currents are used.

ELECTRICAL FIXTURE.—F. L. BUTLER, 740 E. 36th St., Chicago, Ill. An object of the invention is to provide an electric fixture in which the stem is effectively insulated from the parts supporting the stem in position so that an electric current is prevented from passing from the current carrying system to the parts of the fixture, without the use of an auxiliary insulating joint such as would otherwise be required.

TELEGRAPH INSTRUMENT.—J. V. GUERRE, Santiago De Cuba, Cuba. An object of the invention is to provide an improved mounting for the parts of the instrument so that the magneto can be adjusted to vary the gap between the magnet cores and the armature operated thereby. A further object is to provide means for controlling and adjusting the elastic support of the armature carrying lever.

APPARATUS FOR PROPAGATING AND INTENSIFYING ELECTRICAL OSCILLATIONS.—J. J. CALLAGHAN, P. O. Box 574, So. San Francisco, Cal. The invention relates to wireless apparatus and has for its object the provision of a construction for propagating and intensifying electrical oscillations so as to approach the frequency of light waves. Another object is to arrange short period oscillating coils in line, with their respective planes parallel in conjunction with a mirror whereby the propagated wave will be unidirectional.

## Of Interest to Farmers

AGRICULTURAL IMPLEMENT.—J. VERSTEEG, 802 Pittsburg St., St. Johns, Oregon. The invention has for its object to provide in an implement of the character specified, a means for thoroughly cutting and breaking up the soil as it is turned up by the plow, the said means working upon the strip of earth turned by the plow and being operated by the movement of the plow.

## Of General Interest

LAMINATED GLASS.—M. W. GLEASON, address R. B. Cressman, c/o Gleason-Tubout Glass Co., 200 5th Ave., New York, N. Y. This invention has particular reference to the construction of vitreous objects such as globes for electric lamps or the like in which the shell is composed of a plurality of laminæ, the innermost of which is of a distinctive color, the outermost of which is clear, while the intermediate layer is of a translucent nature with a neutral tint. Among the objects is to produce a light very similar to natural daylight with an increased strength of globe.

SAFE.—A. H. GERNSBACHER, 1405 Canal St., New Orleans, La. The invention has for its object to provide mechanism of the character specified, for the safe storage of jewels, money, and the like wherein a safe is incorporated in the hollow metal post or posts of a bed, in such position as will always be convenient for the user, the chamber formed being provided with partitions arranged transversely, and having a door provided with a lock.

AUTOGRAPHIC ATTACHMENT FOR CAMERAS.—M. B. BOYCE, 2 5th Ave., Haverhill, Mass. This invention relates more particularly to autographic cameras, the object being to provide a simple and inexpensive means in the form of a series of letter and numeral blocks movable in guided relation, whereby to produce even, legible exposure titles and similar data upon negatives capable of ready manipulation and uniform exposure.

LADDER.—F. M. DE SAUSSURE, JR., 801 E. North St., Greenville, S. C. This invention relates more particularly to folding ladders especially those in which the side rails are swingable by virtue of pivoted rungs toward and away from one another; among the objects is to provide means automatically acting in connection with a supporting surface whereby to lock the said rails of the ladder section in non-shiftable relation when engaged with a supporting surface either in a horizontal line or upon more or less of an incline.

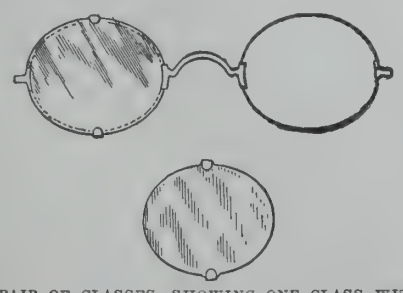
PROTECTED PNEUMATIC HEEL.—W. E. KAY, 422 E. Broad St., Elyria, Ohio. The objects of the invention are to provide a pneumatic heel in which air is confined under pressure, and in which the amount of resiliency is variable under variable pressure according to the weight of the individual wearing it. One of the important features is that the weight will be evenly distributed over the entire wearing surface of the heel, another feature is the use of replaceable tread members so that the wearing position is always renewable without disturbing the body of the heel.

MOP AND BRUSH HOLDER.—L. WECHSLER, 514 W. 126th St., New York, N. Y. This invention relates to scrubbing and brushing apparatus and has particular reference to a device designed to hold either a mop head or a scrubbing brush. Among the objects is to so construct a mop stick and attachment means at the end thereof as to accommodate the device for holding and manipulating any one of several different types of cleansing devices.

SAFETY RAZOR.—A. H. BRYANT, Glen Ridge, N. J. Among the objects of the invention is to provide a holder for a thin blade which will expose the entire length of the cutting edge of the blade and which will hold the cutting edge firmly along a predetermined line in respect to the holder. A still further object is the provision of a holder for a safety razor blade which is formed comparatively thin and compact and with all the resilient members formed as integral parts of the head.

WHISTLE.—J. C. WARD, 817 E. 17th St., Little Rock, Ark. The invention relates more particularly to a whistle to be placed between the lips of the user and in which the body of the whistle is formed with a transverse orifice, the sound being produced by blowing air across the orifice. The invention is also provided with a movable member under the control of the user and arranged to be vibrated to produce trills or intermittent whistling sounds as well as the clear strong whistling sound.

SPECTACLE SHADE.—K. R. GITTERMAN, c/o A. C. Harragin, 30 Le Compt Place, New Rochelle, N. Y. An object of the invention is to provide a tinted or clouded eyeglass shade preferably made of celluloid which may be mounted on the frame or lens of the eye glass or spectacles in order to form a pair of shaded spectacles or eyeglasses. It is an object to provide shade pieces which are small and convenient to handle, and which may be



A PAIR OF GLASSES, SHOWING ONE GLASS WITH SHADE HOOKED ON

carried in the spectacle case with the glasses and be placed in position over the lenses and held there by hooks and removed at will. The same inventor has also been granted a patent for spectacle frames, which may be used in connection with the shades so that a simple shade may be slipped in position into the rim holding the lens.

MARKING DEVICE.—G. J. ANDERSON and W. R. SMITH, 4808 Superior Ave., N. E., Cleveland, Ohio. This device is adapted particularly for branding articles such as rubber tires, inner tubes and the like. It is designed for efficient use with articles having curved, rounded or other abnormal forms or contours. The dies or stamps are adjustably held in the device and can be manipulated while the device is in use so as to contact efficiently with the surface to be marked.

ILLUMINATING ATTACHMENT FOR TELESCOPES.—E. L. BECK, Manor, Pa. The object of the present invention is to increase the utility of telescopes by providing an illuminating device to render the cross hairs more visible. This is of particular advantage in surveying instruments. The illuminant consists of a light cell attached to the eye piece, which contains a small electric lamp and reflector that casts the light upon the cross hairs.

LIQUID DISPENSING DEVICE.—W. F. LERCH, 30 Fannington Ave., Hartford, Conn. The purpose of this invention is to furnish a convenient form of container for iodin or similar liquids, such as antiseptics or astringents, to treat cuts, wounds, sores and the like. It is particularly adapted for the treatment of the throat and gums, for surgical and dental operations and for the treatment of insect bites.

ACCOMMODATION LADDER FOR MARINE VESSELS.—E. J. SIMS, c/o Bauer, 223 Schermerhorn St., Brooklyn, N. Y. This ladder is arranged to be conveniently moved into position for use over the side of a vessel or to be returned to inactive position on a deck when not in use. Means are provided to prevent the stairway or ladder from being broken or otherwise damaged while being moved into active position or back into inactive position.

SLIP COVER FOR CANS.—H. L. STRONGSON, address Loeb-Strongson Corporation, 25 East 112th St., New York, N. Y. The invention relates to tableware, milk tins, or sealed cans of all varieties, and provides a cover to conceal the unsightly appearance of the milk tin when it is placed on the dining table. The slip cover is of pleasing appearance and is provided with a pouring spout.

CONSTRUCTION OF OPHTHALMIC MOUNTINGS.—O. G. SCHUTZE, 73 Victoria Street, Forestville, near Adelaide, State of South Australia, Australia. By means of this invention, lenses of rimless spectacles or pince-nez may be secured to their straps to be adjusted as either "central," "inset" or "offset," and either in "level" or in "lowered" position. The invention also simplifies the assembling of individual members of the mounting in the case of pince-nez.

METHOD AND APPARATUS FOR CONSTRUCTING CONCRETE PILES.—S. M. COTTEN, c/o Office Engineer, City Engineering Department, Phoenix, Ariz. The invention reates to the construction of "cast-in-place" concrete piles. It provides a new method of driving and casing the hole in the ground (into which the concrete pile is cast) so as to develop a minimum of resistance to penetration. This object is accomplished by using telescoping cylindrical sections so designed, related and actuated that skin-friction between the casing and the ground penetrated is practically eliminated.

MERCURY-VAPOR LAMP.—M. J. CORNU, 26 Rue de Babylone, Paris, France. This lamp consists of a thick-walled quartz tube containing two electrodes between which an arc of small length but of high specific brilliancy is formed. The thickness of the tube is equal to at least half the internal diameter, so that the heat of the arc is retained and the mercury vapor is maintained at a high temperature.

AWNING.—W. H. MCOMBER, 803 Chicago Ave., East Chicago, Ill. The present invention covers an improved awning particularly designed for internal use at windows or other openings for supplying a continuous current of cool air to the sleeper in a bed adjacent to the window. The construction is such that the air is constrained to flow in at the lower part of the casement over the face of the sleeper and out above the upper casing.

CAN WASHER.—G. C. WILTSIE, 320 Avenue B, Schenectady, N. Y. One of the principal objects of this invention is to provide means whereby the cream ordinarily left in a milk can after the same has been emptied may be saved. It is quite common in a creamery or ice-cream plant for as much as a pint or a quart to adhere to the can. By means of a rinsing and sterilizing apparatus this cream may be washed out of the receptacles and recovered.

GUN CONTROL.—S. MCG. THOMPSON, Box 745, Fernandina, Fla. Special means are provided in this invention for controlling a gun mounted on the deck of a vessel so as to keep it normally in a horizontal position, or in any other predetermined position regardless of the roll of the vessel. A U-shaped mercury tube mounted upon the gun is arranged to control certain motor operated devices for elevating and depressing the gun so as to keep it always trained on the target.

WELL BUCKET.—C. D. BEHAN, Stigler, Okla. Mr. Behan provides in the present in-

vention a bucket especially designed for use in wells of small diameter, for instance, cased wells. The bucket is provided with a valved bottom so that it can fill from the bottom without having to be tilted. In the same way it may be emptied from the bottom when at the top of the well.

BALL BEARING COUNTER.—R. B. Austin, Deceased (Cyrus B. Austin, Administrator), Delaware, Ohio. In order to provide a rapid means of taking any predetermined number of balls from a container and thus dispensing with the necessity for the separate counting of them the inventor provides a plate formed with a predetermined number of perforations in which the predetermined number of balls will be held while the remainder will roll off when the pate is tipped.

ICE-CREAM DISPENSING DEVICE.—W. L. Hix, 1306 Gartland Ave., Nashville, Tenn. The object of this invention is to provide a device by means of which quantities of ice cream of various flavors may be held in a single container and may be dispensed from the bottom of the container in blocks of predetermined size. Means are also provided for gradually moving the cream downward in the container as it is removed at the bottom.

CLOSET VENTILATOR.—E. A. Johnston, Park Ave., Johnstown, Pa. A motor-driven exhaust fan is employed for exhausting the air from the bowl and a float and seat operated switch are provided for controlling the action of the motor and fan. A switch having a spring pressed plunger holds the seat in a normally slightly elevated position and means are provided for throwing the switch and stopping the motor upon flushing the bowl.

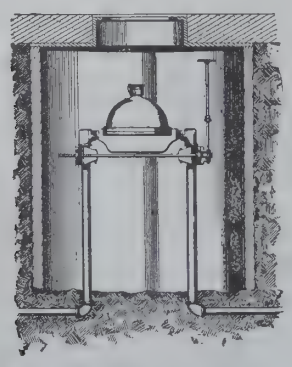
COMBINED ADVANCE DISCOUNT VOUCHER CHECK, ORDER, AND COMMERCIAL LETTER.—J. H. Camp, Ravenswood, W. Va. The invention relates to a written instrument or combined voucher check, blank order and personal letter from the seller to the purchaser, and a blank letter for reply to the seller from the purchaser. The invention aims to eliminate the necessity on the part of the traveling salesman in disposing of merchandise.

TUBE CAP.—A. Landgrebe, 1724 Barnes Ave., Van Nest, Bronx, N. Y. Among the objects of the invention is to provide means whereby the conveying tubes for dispensing beverages may be kept in a most sanitary condition, but providing for the most expeditious cleansing of the same when necessary. The caps as well as the tubes may be made of any suitable material such as glass, porcelain or the like.

## Hardware and Tools

CLIPPER.—J. W. Price, Box 651, Henryetta, Okla. The invention has for its object to provide a simple inexpensive mechanism of the character specified suitable for any form of clipping, wherein the parts are easily operated, may be easily disassembled for any purpose, and are practically noiseless in operation.

METER SUPPORT.—C. C. Bradfield, Harbor Springs, Mich. The invention relates more particularly to meter supporting connections within meter boxes, the object being the provision of mechanism by which a meter may be readily and quickly removed and replaced



A VERTICAL TRANSVERSE SECTION THROUGH THE METER BOX, SHOWING INVENTION

from the cover of the box in such a way as to insure rigid support of the meter in its operative position, and effective non-leaking connection between the meter nipples and the elbows.

PORTABLE CLAMP.—A. Anthony, 1037 N. Castle St., Baltimore, Md. This invention relates to clamps used in wood working, a purpose is the provision of a simple clamp of the type comprising a stationary jaw and a movable jaw, and cam actuating means for securing the movable jaw in any adjusted position; in this device screws are eliminated and in their stead cam levers substituted, permitting of quick adjustment.

DETACHABLE SPRING HINGE.—P. Klein and H. Humphrey, 181 Glessner Ave., Mansfield, Ohio. An object of the invention is to provide a detachable spring hinge composed of two levers, and consisting of only two parts, the part fixed to the door or window frame and the part associated with the spring so that no spare parts will become lost when the hinge is not in use. Another object is to provide a spring which will allow of quick and easy removal of the door or window from its frame.

SHADE FIXTURE.—W. McC. Neale, Box 351, Greensboro, N. C. This invention has for its object to provide a simple, efficient, inexpensive device for permitting a shade to be raised or lowered when desired without the necessity of springs and without the necessity of handling the shade itself. A steady continuous pull on a cord will raise the shade and a slight continuous release of the cord will lower the shade. A quick and total release of the cord locks the shade in adjusted position.

TUBE COMPRESSOR.—J. J. Bowes, Jr., 1508 E. Jackson St., Pensacola, Fla. The object of the invention is to provide a device adapted for compressing a flexible tube to prevent the flow of liquid therethrough, as for instance the tube of a syringe, wherein the arrangement is such that the tube will be efficiently clamped shut assuring a water-tight closure without undue wear on the tube.

## Heating and Lighting

WATER HEATER.—De Forest L. Rathbone, Box 1020, Jacksonville, Fla. The object of the invention is to provide an automatic water heater which employs live steam as the heating means for the water, the steam valve being thermostatically controlled by an arrangement of certain of the heater parts with the ultimate result that the temperature of the usable water is kept at a substantially uniform degree.

HEATER.—H. Fickersen, 718 Park Ave., Hoboken, N. J. The invention relates to a heater with a construction of lining which prevents the radiation of heat through the sides of the heater, and directs the heat through the top. A further object is to provide a lining which may be inserted in an ordinary oil heater and which may be adapted for other forms of heater without changing the construction.

ROLL HEATING DEVICE.—A. S. Rice, 108 W. 22nd St., New York, N. Y. The invention relates more particularly to roll warming devices for use in hotels, restaurants and the like. The prime object is to provide a device in which the heat supplied is furnished by a heater of the electric type. A further object is to construct the device in such manner that the heated interior is automatically provided with necessary amount of moisture, to prevent the drying out of the rolls.

## Machines and Mechanical Devices

MACHINE FOR PEELING TOMATOES.—C. Kirino, P. O. Box 418, Ogden, Utah. The invention relates to a machine for peeling tomatoes or other vegetables or fruit having a skin of a nature to be loosened by scalding; it more especially relates to a machine through which the fruit is run and whereby the skin is divided into sections while on the fruit and subsequent operations performed of scalding the tomato and removing the skin sections. A distinguishing feature is the provision of means for impaling the tomatoes without bruising or crushing them.

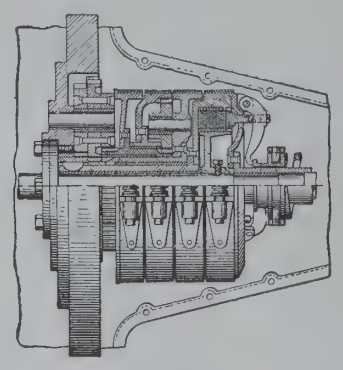
BARREL WASHING MACHINE.—H. Reininger, c/o Consumers Brewing Co., Cleo and Liberty St., New Orleans, La. The object of this invention is to provide a construction whereby the interior and exterior surface of a barrel, package or the like may be substantially simultaneously cleaned. A further object is to provide a single structure in which a number of different steps are provided for the cleaning so that the barrel may be fed in at one end and discharged at the other without manipulation or guidance by an operator, the soaking, washing and scrubbing being carried on automatically.

PERFORATING MACHINE FOR BANK DRAFTS AND OTHER DOCUMENTS.—G. A. Crocco, Rome, Italy. The invention refers to perforating machines in which numbers and words are first prepared singly by rotating the lettered or numbered disks of a setting device which is then brought in such position as to cause groups of pins or punches to pass through and to pierce the paper, leaving in same a number of holes to show the figures or letters impressed.

DETACHABLE FASTENER FOR CYLINDRICAL SCREENS.—W. L. Leach, 110 E. Broadway, Brownwood, Texas. More particularly the invention relates to means to detachably connect and fasten the ends of a strip of reticulate material in order to form a grading cylinder, which may be interchanged and renewed without difficulty, rendering the cylinder adaptable to various uses by inserting screen mesh of different gages.

GLOVE TURNING MACHINE.—D. Baum, Livermore Falls Glove Co., Livermore Falls, Me. Gloves, particularly the cheaper grade of cotton, canvas and similar woven material, are made wrong side out and must be turned before forwarding to the trade. The invention has for its object to provide means for quickly turning the gloves, the device operating entirely automatically.

PLANETARY GEARING.—S. V. Dickman, Shavertown, N. Y. An object of this invention is to provide means whereby three forward speeds and a reverse can be transmitted from the drive shaft to the driven shaft by the selective operation of brake bands controlling



A VIEW PARTLY IN ELEVATION, PARTLY IN SECTION

drums. A further object is to provide mechanism of the character stated which is compact in assemblage, comparatively simple in construction and strong and durable in use.

WAVE MOTOR.—J. W. Southwick, 752 Excelsior Ave., Akron, Ohio. The invention has for its object to provide mechanism for converting the energy of the waves into useful work. The device comprises a reservoir, a funnel-shaped passage leading from the shore to the front wall of the reservoir and adapted to receive the breaking waves, a pipe leading from the small end of the passage delivery to the reservoir, and turbines in the bottom of the reservoir for utilizing the water power.

MACHINE FOR MAKING PAPER BOXES.—A. W. Harris, Sleepy Eye, Minn. This invention relates more particularly to a machine for the making of box bodies open at the top and bottom, and such as are used by florists, market gardeners and other persons for growing young plants therein to be subsequently transplanted in lieu of the flower pots heretofore used for this purpose, such boxes being known in the trade as dirt bands.

DOOR OPERATING MECHANISM. — J. Baloc, 742 Altic St., Hazleton, Pa. The object of the invention is to provide an automatic door opening mechanism particularly designed for opening and closing garage doors and the like, and arranged to open the doors by an advancing automobile, to keep the doors open until the vehicle has safely passed and finally to close the doors and hold the same in closed position.

EMBROIDERING MACHINE.—J. G. F. Rooker, Vryenban, near Delft, Netherlands. The invention relates to a machine for automatically sewing characters, figures, etc., in woven materials and the like. The machine is arranged in such a manner that a predetermined character, word or number can be sewed once in a piece of material or more than once subsequently in different pieces of material, the machine needing to be adjusted but once.

VALVE.—S. J. Connell, 115 9th St., Brooklyn, N. Y. The invention relates more particularly to a valve for steam traps, the purpose being to permit the exhaust of water of condensation when the latter reaches a predetermined level, an object being to provide a valve which can be quickly assembled, which will maintain a higher closure, and which will comprise but two main parts coupled together without employing nuts, bolts or other removable devices.

ATTACHMENT FOR EARTH-WORKING MACHINES.—L. H. Towner, 3rd and Lake Sts., Muskogee, Okla. Among the objects of the machine is to provide an attachment for a road grader or road drag, to prevent the side draft or side skidding of the rotatable disk, an to provide for its operating within the earth for a suitable distance, and to provide means to vertically adjust the anti-skidding disk, so that it may be elevated above the earth during the transportation of the machine.

SAFETY GUARD FOR PUNCH PRESSES.—A. Koetting, 423 Wythe Ave., Brooklyn, N. Y. The object of this invention is to provide an automatic guard or fender adapted to be brought successively into position to protect the operator's hands from injury due to the descent of the power operated tool such as a punch, die, or the like. The device will not interfere with the normal intended operation of the machine.

PEGGING MACHINE.—J. Larsen, 13 Frederik den VII Gade, Copenhagen, Denmark. The invention relates to a pegging machine for use in the shoe-making industry. The machine performs the pegging in a manner strikingly resembling hand work, the peg being forced down into the hole produced by the awl by a hammer stroke which is like the strokes by which the shoe maker drives in pegs.

MACHINE FOR FORMING ROLLS ON TOY BALLOONS.—H. R. Gill, c/o Eagle Rubber Co., Ashland, Ohio. An object of the invention is to provide an arrangement of rotary brushes having flexible covers thereon of chamois, muslin, cheesecloth or other suitable material, which frictionally engage the open end portion of the toy balloons and roll the same to form a bead thereon. A further object is to provide means for guiding and feeding the balloons to the head forming device.

APPARATUS FOR PRODUCING DRIVING BELTS.—A. Carlsen, Lyngby, near Copenhagen, Denmark. The object of the invention is to use cross-woven linen tracks, i. e. linen in which all the threads run diagonally and all end in the edges, which by a special gluing machine are gued together in plies. By using diagonally woven linen the belt does not fray in the edges, its strength is increased, and it is not so liable to be destroyed by running on small pulleys.

GLOBE VALVE.—W. H. Johnson, 6217 Loomis Bldg., Chicago, Ill. The invention has for its object to provide mechanism in connection with valves, so arranged that whenever the valve is turned to open or close it will be ground at its seat to provide for intermittent regrinding of the contact surfaces of the valve and seat, and wherein the controlling mechanism is outside the valve casing.

DENTAL CROWN-MAKING MACHINE.—I. Navarro, M. Santa Capilla a Majares No. 15, Caracas, Venezuela. Among the principal objects of the invention are to facilitate the manufacture of dental crowns, to provide a power machine having substitute parts to permit employment of a machine for various operations, and to provide a machine for performing the entire operation resulting in completing the crown.

## Medical Devices

DOUCHE CAN.—F. J. O'Rourke, 8th Ave., Whitestone, N. Y. The object of the invention is to provide douche cans with diaphanous indicators whereby the user can see at a glance when the water or medicated liquid contained in the can begins to flow out to the afflicted part, and whereby the user can gage the amount of liquid discharged. Another object is to protect the indicator which is usually glass, against accident and to readily replace the same in case it becomes defective.

## Musical Devices

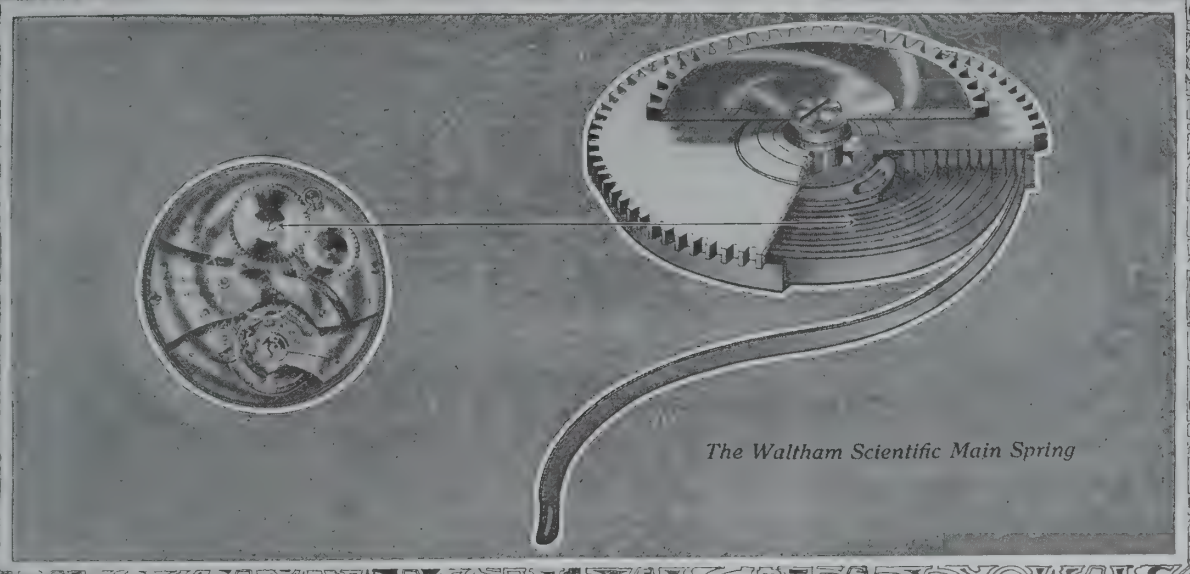
SOUND BOX FOR PHONOGRAPHS.—A. Rogati and L. Aronne, Kimberly Phono Co., 226 Fayette St., Perth Amboy, N. J. The invention relates to sound producing machines. Among the objects is to construct a sound box with front and rear walls, and provide means for connecting the periphery of one wall to that of the other. Another object is to provide means coöperating with the stylus bar for varying the volume of the tone produced by the machine.

REPRODUCER FOR TALKING MACHINE.—J. W. Kaufmann, 1730 N. Monroe St., Baltimore, Md. The object of the invention is to provide a connection between the needle and the diaphragm controlling lever which will eliminate the usual rigidity between these parts, substituting a resilient connection, of a substantially U-shaped spring connecting the needle holder with the reproducing lever.

PLAYING DEVICE FOR STRINGED MUSICAL INSTRUMENTS.—C. Haberman, 87 Ferry St., North Bergen, N. J. The object of this invention is to provide a playing de-

(*Continued on page 388*)

# PROOF



THE MOST SCIENTIFICALLY BUILT WATCH IN THE WORLD

## The Waltham Scientific Main Spring— The Power That "Drives" Your Watch

THE Main Spring is to a watch what gasoline is to an automobile — the power that drives the mechanism.

With this difference — that the Main Spring of a watch must supply power with a constant and even tension — with no acceleration or diminution in order to secure accurate time-keeping.

A Main Spring should measure in length, width and thickness correctly for the particular size of watch it is to fit — as, for example, a Main Spring for a gentleman's size high-grade watch should measure 25 inches in length and be approximately three times the thickness of a human hair.

The problem that confronted watchmakers was to produce a Main Spring without any variation of thickness for its entire length. This problem was solved by John Logan, an inventor of the Waltham Watch Company, who perfected a method and created the machines which have made Waltham the largest and most famous Main Spring producers in the world.

The superior time-keeping ability of Waltham Watches created a world demand for Waltham Main Springs.

You will observe in the illustration (above) that a unique feature of the Waltham Main Spring is the reverse curve, so difficult to produce, yet so essential to time-keeping dependability.

This reverse curve adds power as the spring tension diminishes, giving the Waltham Watch an equality of motive power during the twenty-four hour interval of winding.

From the brief description and proof it is easy to understand that the unscientific hand-made Main Spring will cause erratic time-keeping and dissatisfaction.

The Waltham Scientific Main Spring protects the money you pay for a watch and provides another important reason why your Watch Selection should be a Waltham.

# WALTHAM

## THE WORLD'S WATCH OVER TIME

## RECENTLY PATENTED INVENTIONS

(*Continued from page 386*)

vice more especially designed for playing the melody strings without the use of picks. Another object is to construct the device in a simple manner, and to enable the player to sound the strings with a tremolo effect in case such is called for by the music.

### Prime Movers and Their Accessories

ROTARY ENGINE.—J. G. PORTER, 914 Macdonald Ave., Richmond, Cal. This invention relates more particularly to rotary engines which are operated by direct and expansive pressure of a motive fluid or gas introduced therein, and has for its object to produce an engine which shall be simple in construction and operation and in which the operation is wholly internal and having an adjustable expansion control.

LOCKING DEVICE FOR ECCENTRIC BUSHINGS.—F. J. MCAVOY, 496 Clinton Ave., Newark, N. J. The invention relates to internal combustion engines such as are in use on automobiles. The object is to provide a locking device for eccentric bushings arranged for convenient attachment to the engine or motor to lock the eccentric bushing in place and to allow of using the device as a spanner wrench for turning the eccentric bushing after the same has been unlocked.

Another patent granted to the same inventor provides a locking device for a bushing provided with an eccentric on which is journaled a sprocket wheel engaged by a sprocket chain to be tightened, the said sprocket wheel being connected with the shaft of the motor generator and the sprocket chain being driven from the motor shaft and driving the motor cam shaft and the ignition timer shaft.

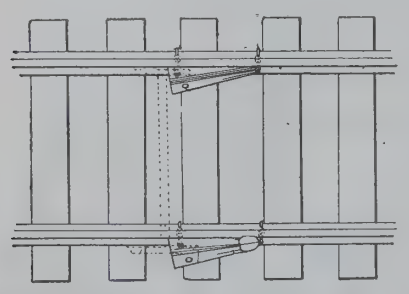
MULTIPLE INTAKE MANIFOLD.—H. P. STURM, Clarksburg, W. Va. The foremost object of the invention is to provide a manifold for an internal combustion engine, which is so designed and constructed that the proper velocity of the fuel is maintained at all engine speeds, retaining the original atomization created in the carburetor and preventing condensation on the walls of the manifold; a further object is to provide means whereby the auxiliary or high speed conduit can be cut in either automatically or manually.

INTERNAL COMBUSTION ENGINE.—G. S. MACDONALD, 114 E. 19th St., N., Portland, Ore. An object of the invention is to provide an engine which will operate economically and efficiently on crude oil, fuel oil and other liquid fuels. A further object is to provide a device having means for maintaining a supply of fuel, under constant pressure to an atomizer which discharges into a combustion chamber, the latter being filled with compressed air and the walls of the chamber being heated so as to ignite the mixture.

SPARKING PLUG FOR INTERNAL COMBUSTION ENGINES AND METHOD OF MANUFACTURING THE SAME.—C. E. GERBAUD, 102 Rue Pelleport, Paris, France. The primary object of the invention is to provide a sparking plug, the constituent parts of which are so united as to form a single integral piece which will have the effect of obviating the leakage of gas or lubricating oil. A further object is to provide a plug capable of withstanding very great temperature and heavy pressure.

### Railways and Their Accessories

CAR REPLACING DEVICE.—W. MATNEY, Box 32, Stone, Ky. It is the purpose of the invention ot provide a device for replacing cars upon the rails of a track. A further object is to provide a simple device which is reversible and may be employed for replacing

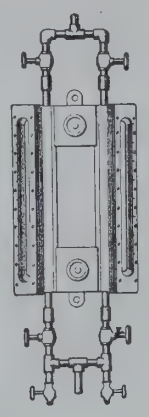


VIEW SHOWING TOP PLAN VIEW OF TRACK WITH DEVICE APPLIED

cars upon the track in either direction, having interfitting connections with the heads of the rails of a track and means which coacts with the rails for securely holding the device in operative position.

DRAW BOARD FASTENER.—A. JAEGER, 671 Front Ave., Grand Rapids, Mich. An object of the invention is to provide a fastener which is especially adapted for securing a draw board against movement and which will permit the easy removal of the fastener when desired. The invention particularly relates to such draw boards as are used in loading or unloading freight cars from docks, platforms, etc.

WATER GAGE.—D. M. MCCOOK, 409 3rd St., Manchester, Ga. A purpose of this invention is to provide a plurality of water gages arranged to give the same indications which can be observed from various angles so



SHOWING A FRONT ELEVATION AND ARRANGEMENT OF GAGES

that when applied to the boiler of a locomotive the quantity of water in the boiler can be readily determined by the engineer and fireman without moving from their respective working positions.

DOUBLE HEADING AIR BRAKE SYSTEM.—E. R. HEWITT, 15 Macomb St., Plattsburg, N. Y. This invention relates to trains headed by two or more locomotives; its object is to provide an air brake system arranged to place the engineer of the first locomotive completely in control of all available air pressure of the several locomotives. Another object is to utilize the air pressure of the main reservoir of the second locomotive to automatically assist the train pipe air pressure from the first locomotive in recharging the auxiliary reservoir of the train.

### Pertaining to Recreation

RACE GAME APPARATUS.—R. M. BRENNER, P. O. Box 151, Palisade, N. J. Among the objects of the invention is to provide a game apparatus for use in pleasure grounds, parks and other places and arranged to enable a number of players simultaneously to manipulate racing objects such as figures of horses with a view to cause such objects to travel over individual tracks thereby simulating a race, the winning being solely dependent on the skill of the player.

TOY FORT.—H. E. COATES, 2015 Stoatway, Sacramento, Cal. The invention more particularly relates to a toy fort on which a gun is mounted and from which a figure representing a gunner is adapted to emerge upon the tripping of a trigger controlling the mechanism, the arrangement being such that as the figure emerges the gun will be automatically fired to give the effect of having been fired by the gunner.

AUTOMATIC SELF-PROPELLED TOY TANK.—C. A. LEWIS and H. E. SMOCK, c/o Die Products Co., Dayton, Ohio. The invention has for its object to provide means which will automatically operate to cause a toy tank to travel or move forward in an irregular course or path. Another object is to provide means for causing one end of the tank to move up and down in a vertical plane when driven, and to cause the guns thereon to be oscillated or moved when the tank is in motion.

### Pertaining to Vehicles

SCREEN FOR WINDSHIELDS.—F. MCMAHON and R. A. HOUSTON, South Charleston, Ohio. This invention has for its object to provide a device wherein a perforated curtain is provided, having means at its ends for permitting it to be connected to the windshield supporting frame of a motor vehicle, to prevent the passage of bugs and the like when the shield is open.

LOAD CARRIER FOR AUTOMOBILES.—W. K. YOST, Box 488, San Antonio, Texas. An object of the invention is to provide means for carrying sample trunks or other loads at the rear of the tonneau of an automobile. The device is more particularly intended for use as an attachmet for a roadster with flat body extension. The carrier can be quickly applied or removed and folded into small space for storage.

ELEVATING TRUCK.—C. M. HENDERSHOTT, 39 Adsit St., Hornell, N. Y. The invention has for its object to provide a truck of the character stated which can be easily operated, and which will be of maximum strength and durability; the platform may be given any elevation desired and when elevated will securely support the load thereon.

LICENSE CARD.—C. H. CORNELL, Valentine, Neb. This invention has for its object to provide a card of the character specified especially adapted for use with motor vehicles wherein the card has a form providing for a complete description of the car and of the owner or other person to whom the card is issued and designed to be used with a plate or license tag.

GEAR SHAFT.—W. G. DRUMMOND, 112 S. 6th St., Alhambra, Cal. The invention relates to transmission devices for automobiles and motor cars, and particularly to gear shifting devices for use in connection with constant mesh gear sets, the object being the provision of an arrangement which will permit of manual selection of the gears to be engaged and automatic completion of the selected engagement when the clutch is disengaged.

TIRE HOLDER.—A. F. ENGEL, 650 Wayne Ave. An object of this invention is to provide a tire holder such as is commonly carried on motor vehicles and which permits ready insertion or removal of the tire. A further object is to provide a holder which can be swung to one side to provide a free entrance or exit for the tire, and which when moved into position and locked, will securely hold the tire against accidental movement.

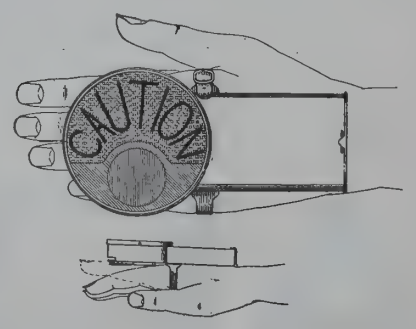
AIR PUMP.—S. S. AVERY, Pleasant Lake, Ind. The invention relates more particularly to hand pumps for inflating pneumatic tires. One of the principal objects is to provide a single cylinder pump in which the operation is double acting. A further object is to construct the pump cylinder in such a manner that up stroke of the piston is limited in its length and cushioned by a body of air which is trapped in the top of the cylnder.

RESILIENT WHEEL.—T. T. CHALONER, 510 W. 47th St., New York, N. Y. The object of this invention is to provide a construction whereby a resilient effect may be secured and at the same time any skidding or side strain taken up without injury to any of the parts. A further object is to provide a resilient wheel which is formed in sections with a set of springs and a casing therefor formed at the outer part so as to give sufficiently to allow of a proper action of the springs.

OIL FEEDER.—A. E. NICHOLLS, Wilson Creek, Wash. This invention has for its object to provide a feeder especially adapted for use with internal combustion engines of motor vehicles, the arrangement being such that all the bearings of the crank shaft will be thoroughly lubricated regardless of the degree of inclination of the oil pan.

ROAD SHOE FOR AUTOMOBILES.—L. S. ROBBINS and W. E. GILMORE, 706 Walnut Ave., Klamath Falls, Oregon. Among the objects of the invention is to provide for each of the rear or traction wheels a gripping device adapted to be introduced beneath the forward bottom side portion of the wheel to enable an automobile or similar vehicle to easily and quickly extricate itself from a mudhole or other road difficulty, the device being so constructed as to enable the wheel to secure adequate hold on the road.

AUTOMOBILIST'S CAUTION SIGNAL.—W. W. KUHLMANN, 124 29th St., Woodcliff-on-Hudson, N. J. The invention relates to a signal device which includes a battery, lamp, switch and signal element and is adapted to be worn on the sigaling hand of an automobilist

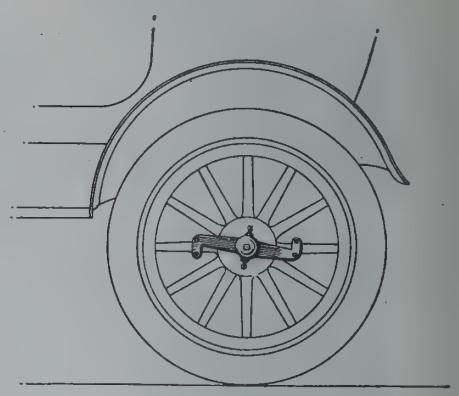


AN ELEVATION AND VIEW SHOWING HOW THE FINGER IS USED TO CLOSE THE LAMP CIRCUIT

so that in driving at night he can warn the driver of a car in the rear of the fact that he is slowing down to make a stop or turn.

REVERSING FAN.—P. JENSEN, Wayne, Alberta, Canada. This invention particularly relates to fans for circulating air about automobile engines and through automobile radiators. An object is to provide a radiator cooling fan of the reversible type which is controllable from the driver's seat so that the volume of air may be varied to suit the temperature needs of the automobile engine.

REPAIR HUB AND WHEEL PULLER.—C. N. SRADER, 116 W. Elm St., Enid, Okla. The invention has for its object to provide a device especially adapted for use in repairing broken Ford rear hubs, for permitting the car

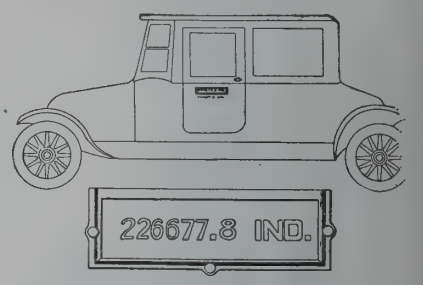


REAR WHEEL OF VEHICLE WITH REPAIR HUB IN PLACE

to be used after the hub is broken and to be safely driven a reasonable distance, as for instance, to a repair shop. The device comprises a cap being internally threaded for engagement with a hub and arms extending from the cap engageable about the spokes.

LUBRICATING PACKING.—H. A. LACERDA, c/o R. W. Benson, 50 Church St., New York, N. Y. The invention relates to automobiles having a rear axle housing through which extends the rear or driving axle. The object is to provide a lubricating packing filling the spaces between the rear axles and the rear axle housings, intermediate the inner and outer roller bearings, and capable of preventing the lubricant within the gear casing from leaking out through the outer end of the housing and onto the tires.

SYSTEM FOR NUMBERING MOTOR CARS.—J. L. CATLETT, Vincennes, Ind. An object of the invention is to provide a simple method of numbering motor vehicles, so arranged that the vehicle may be guarded against theft, and the State against loss of fees, wherein a per-



SIDE VIEW OF CAR AND PLAN VIEW OF REMOVABLE HOLDER

manent number is provided for each car, and a removable record of the said number for each car. Two sets of plates being furnished by the State, and various colors indicating various years, every year the owner surrendering one set of plate and obtaining the other.

### Designs

DESIGN FOR A TABLE.—G. POLL, c/o G. W. Poll & Co., 1918 Harman St., Brooklyn, New York.

DESIGN FOR A FINGER RING.—J. SIMMONS, c/o Goldman Kolber Co., 206 Broadway, New York City, N. Y.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

*"We Must Fly To-night"*

Out of a deep sleep he woke her. She thought she knew him so well. Yet now, at two in the morning, he burst on her with this terror—this mystery—this what?

It's the beginning of one of the best mysteries ever solved by the great detective,

**CRAIG KENNEDY**
*The American Sherlock Holmes*
**ARTHUR B. REEVE**
*The American Conan Doyle*

He is the detective genius of our age. He has taken science—science that stands for this age—and allied it to the mystery and romance of detective fiction. Even to the smallest detail, every bit of the plot is worked out scientifically. For nearly ten years, America has been watching his Craig Kennedy—marvelling at the strange, new, startling things that detective-hero would unfold. Such plots—such suspense—with real, vivid people moving through the maelstrom of life! Frenchmen have mastered the art of terror stories. English writers have thrilled whole nations by their artful heroes. Russian ingenuity has fashioned wild tales of mystery. But all these seem old-fashioned—out-of-date—beside the infinite variety—the weird excitement of ARTHUR B. REEVE'S tales.

**FREE 10 Volumes POE**

To those who send the coupon promptly, we will give FREE a set of Edgar Allan Poe's works in 10 volumes.

When the police of New York failed to solve one of the most fearful murder mysteries of the time, Edgar Allan Poe—far off in Paris—found the solution. The story is in these volumes.

He was a detective by instinct—he was a story-teller by divine inspiration. Before or since—no one has ever had his power to make your hair stand on end—to send chills up your back—to hold you in terror—horror! To read breathlessly—to try to guess the ending—to enjoy the perfect, flawless style—to feel the power of the master—that is all you can do in each and all of Poe's undying stories.

This is a wonderful combination. Here are two of the greatest writers of mystery and scientific detective stories. You can get the Reeve at a remarkably low price and the Poe FREE for a short time only.

**HARPER & BROTHERS**
(Established 1817)

Cut out this coupon and mail it today

**HARPER & BROTHERS, 21 Franklin Square, New York** Sc. Amer. 10-20.

Send me, all charges prepaid, set of Arthur B. Reeve—in 12 volumes. Also send me, absolutely free, the set of Edgar Allan Poe—in 10 volumes. If the books are not satisfactory, I will return both sets within 10 days at your expense. Otherwise I will send you $3.50 within 5 days and $3.00 a month for 12 months.

## A New Deal in the Transportation Industry

(*Continued from page 374*)

would never pay to lay rails but where there will be a large profit in using from one to two or three dozen trucks. This use, as it increases, will add greatly to the value of farms along the truck routes opened up, bring increased prosperity to the farmers and increased and cheaper food supply to the country.

To the shipper and to the general public the short haul by rail means the same excessive transportation costs that it does to the railroads. In the past years, there was no alternative. If the shipper wanted to send his product from Cleveland to Akron, he had no vehicle available other than the railroad. Although delays have been hindering more in recent years than in the past, these delays have always been a serious factor in the short-haul. Shipping time has always been out of proportion to the distance traveled on the short-haul. Furthermore, packing and crating charges which are unnecessary with trucks must be figured into the cost of the product to the consumer on all railway freight. The shorter the distance travelled, of course, the higher is the proportion of this cost.

One gain to be readily seen in any comparison between the railroad and the motor truck is the saving in favor of the truck on such items as packing and crating, cartage, tracing, switching and demurrage. While figures on all items of this nature are not always available and even when found sometimes present wide variations depending upon tonnage hauled, terminal facilities, character of freight, etc., the following costs, expressed in cents per hundred pounds, as determined by a large manufacturing company in New York, are representative:

Cartage charges from shipping platform to railroad siding, 15; cartage from freight house to consignee's receiving platform, 15; crating and packing, 24; with an additional 17 per cent increase in freight charges, due to the increased weight of shipments occasioned by crating and packing material. This totals $10.80 a ton, which must be added to freight costs.

Now that the increased freight tariffs are in force many instances where comparisons of costs in shipping by rail and by truck have heretofore been close, are showing a widening gap in favor of the truck. The largest increase in freight rates, as it happens, has been made effective in the eastern section where the highest development of truck transportation has taken place. With this increase, amounting to 40 per cent, there is every indication that shippers will analyze more closely than ever the cost of shipping by truck as compared with that of the railroad, in order that they may have an accurate picture of the relative saving which may or may not lie on the side of the truck.

Apart from the normal value of the motor truck in hauling freight at lower costs and with less loss of time, there is another factor which enters into the traffic situation of the present day; and that is the ability the truck possesses to relieve the railroads during the period of reorganization. Without a doubt, the railroad systems of the country are going into the next few years with their hands full of perplexing transportation problems, and with far too little equipment to handle their tasks as efficiently as they would like to. This will give the truck a very practical opportunity to show what it can do in relieving the railroads of some of their burdens.

The ability of the truck to assume this rôle has been proven over and over again. In almost every instance where the motor truck has been put to use, figures may easily be compiled to show how substantial this relief has been. The ability of the truck to act as a relief agent to the

# You Helped Me To Fill A Big New Job

***This is the story of a Milwaukee man:***

"The job was big. I needed courage, energy, wise counsel. I needed to make both myself and the men working with me more efficient.

"I carried the application of Mr. Emerson's principles into office and shop, and difficulties were easier to handle, and I was able to show better results.

"I have wished many times that this course had been available when I was 20 years old. I can picture myself a man of much greater efficiency today, had this training started then."

***What efficiency did for him it can do for you—and if your "big job" isn't in sight, efficiency will show you the way to find it. Send the coupon today and find out. It means dollars and cents, health and happiness to you. Send today and find out about the***

# Course in Personal Efficiency

**Prepared by Harrington Emerson** **Conducted by the Review of Reviews Co.**

Thousands of men have already enrolled—employed and employers, professional men and women—each seeking a different goal—each finding through this course a shorter, more direct way to reach that goal. Efficiency is not records nor system, nor red tape; it is not hurry nor bustle—but the way to get the most done with the least effort.

If you never get another bit of knowledge as long as you live, you can be a success anyway. It isn't that men don't know enough—but that they don't organize and use the knowledge they have. Efficiency will teach you how to utilize every bit of knowledge—all the ability—all the energy you have. Efficiency is the science of HOW!

It is like this: Pig iron is worth $13 a ton. Made into horseshoe nails that pig iron rises to $250 a ton. Made into steel rails the price is still higher. Turned into delicate watch springs, that ton of pig iron is worth $250,000. So with your brain. Its value depends on how you handle it. The untrained brain reaches the bread line—the partly trained brain makes a living—the fully trained (Efficient) brain gets to the top. Make yours carry you to the top.

Harrington Emerson is the President of the Emerson Company of New York. Fifteen years ago that company undertook its first big work. The client employed 13,000 men; a strike was on at the time. With the help of the Emerson Company production costs were reduced 25 per cent. There has not been a labor difficulty there since. The earnings of the men were increased over 10 per cent. The amount paid Emerson and his staff was $150,000. Now the Emerson Company has over 100 affiliated specialists of the highest rank. It has helped 200 firms to become efficient. For 40 years Mr. Emerson has been studying, preparing, teaching Efficiency.

**WHAT EFFICIENCY HAS DONE FOR HUNDREDS OF CORPORATIONS IT NOW DOES FOR *YOU* AS AN INDIVIDUAL IN THIS COURSE.**

There is opening before the American business man a great opportunity. After the Civil War during the rebuilding time, the great fortunes of today were founded. In the rebuilding of what Europe has destroyed, in the fulfilling of the duties she has let slip, the great fortunes of tomorrow will be founded.

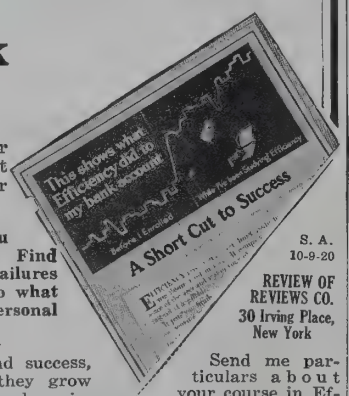
## FREE—This Book

**20 Chapters—In Colors—Illustrated**

Send for this book. It contains the answer to the ever present question of "Where is the money coming from?" It tells you just what Efficiency is—what it has done for others—what it can do for you. Some of the Chapters:

**What is Efficiency? For whom is Efficiency? How you are taught Efficiency? Are you ear-minded or eye-minded? Find out what you are actually doing with your time. Most failures are due to guess work. You use only half your power. To what do some men owe their success? Health culture. Personal finances. Mr. Emerson's message to you.**

It's your next step that counts—the road to Efficiency and success, or to inefficiency and failure—start close together—but they grow wider and wider apart—till finally they can never be joined again. Remember that tomorrow and next day will take you a little further off the right way. Take the right road now, send this coupon today.



S. A. 10-9-20

railroads is proved quite emphatically by the Goodyear Akron-Cleveland route, wherein it is estimated by the National Automobile Chamber of Commerce, 885 freight cars are released every week for other and more profitable service.

This phase of transportation is more vital to the manufacturer, distributor and producer today than it has ever been before. At the present time this country operates approximately 2,400,000 freight cars. If, by the use of motor trucks on a 40-mile haul between Akron and Cleveland, 885 freight cars per week are released for other duties, a proportional saving over the total number of freight cars in operation the country over would mean a tremendous gain.

And the gain would not only be effected in some restricted industrial areas, but would extend to the Middle West and South where transportation is just as important in the work of bringing crops and live stock to market. Transportation is likely to be taken as a problem of local or sectional interest unless the adage of the chain and the weak link is borne in mind.

Transportation enters public life at two points: First, as a connecting link between the producer and the manufacturer; second, between the manufacturer and the consumer. A break in one connection is just as serious as a break in the other. In fact, the perplexing problems of moving the country's merchandise will be far along toward solution once the study of transportation is removed from a narrow, partisan plane and elevated to a position where it demands enlightened public interest.

The direct saving to the consuming public is perhaps the greatest justification for motor truck transportation where conditions are favorable to its adoption. Consider the food staple, milk, for example. One of the largest Detroit creameries distributes on an average of 43,510 gallons of milk every day. Of this quantity, gathered in a radius of seventy miles, 18,570 gallons are shipped into its Detroit plant by motor truck each day, as compared to a total of 16,560 gallons received by rail.

This is one instance where the motor truck, already able to compete with rail transportation on the old freight rates, will find its advantage even more pronounced now that the increase of twenty per cent in milk freight rates has gone into effect. Such savings bear directly on the pocket book of the individual, and as such will be given more and more attention and study as time goes on.

The final outcome of the present movement to let the motor truck assume a larger portion of the country's transportation tasks will mean a saving all along the line from the producer of raw material through the intermediate steps, manufacturer and wholesale distributor, to the public at the opposite end of the line. At the same time, the railroads will benefit by the saving of untold money spent now in handling traffic which as public servants they are required to handle, but which represents a heavy loss due to short, unprofitable hauls in less-than-carload lots. The farther the motor truck advances within its economic field, the greater will be the profit of the railroad, the manufacturer and the consumer.

Naturally, any development conducted on such a broad scale requires time. The railroads spent years in reaching the present point of perfection, and the motor truck will likewise spend considerable time before its maximum results can be felt. No one can say how long the period of development will be. Present-day figures, compiled by the National Automobile Chamber of Commerce, give the national registration of motor trucks as 750,000, and the annual production for 1919 as 316,364.

So far as the total potential tonnage of the motor truck is concerned, it has been conservatively estimated that the yearly average of around 500,000,000 tons will increase five or ten times when the truck is given the traffic now handled by the railroads at a loss, the traffic not handled at all, and the traffic that will appear as soon as facilities are provided.

A statement recently issued by Herbert Hoover pointed out that fifty per cent of farm produce rots on the ground for the want of transportation. There will be an immense amount of new traffic that will arise when means of moving it are provided.

The truck, therefore, appearing at a time when the transportation machinery would collapse without its help, has an almost infinite future. It has only begun to assume the burden it will ultimately bear. Its greatly increased use will be accompanied by vast benefits to its owners, to the railroads themselves, and most of all, to the general public.

## Applying Radium to Cure Man's Ills

(*Continued from page 375*

glass vial, containing the radium, in an "applicator." This is a small brass tube, very accurately made so that the walls are of uniform thickness, with a screw cap, to which is fastened a brass wire. The whole is gold plated to render it sanitary.

The applicator stops the Alpha rays and some of the Beta rays. But to eliminate the Beta rays completely the applicator is placed inside a brass tube or "screen," also made with carefully gaged walls.

This precaution is necessary because when the flesh is exposed to the Beta rays for even a short time a deep burn results, and this is not only painful but dangerous. The bombardment of the metal in the screens by the Beta rays sets up secondary vibrations which also may cause bad burns. As a precaution against these the applicator and screens are wrapped in rubber.

If the spot to be treated is on the surface the radium may be applied in the form of a flat metal plaque, to which the radium is inlaid. Another form of plaque has a corrugated surface on which the glass vials containing radium are placed and the whole is then bound in place.

If the growth to be treated comes to the surface but is deep in the flesh, the radium is placed in the hollow point of a specially made non-corrosive steel needle and this needle is inserted in the growth during the application.

The radium may even be taken internally for the treatment of rheumatism, certain kidney and liver troubles, and intestinal troubles. Of course only a very minute amount is taken, usually in a liquid. The radium is absorbed into the blood and circulates throughout the system. No actual chemical action takes place, however, even when the radium is taken internally. It simply attacks useless tissues, which are then ejected from the body by the excretory organs. There is no danger of burns from the minute quantities which are taken internally.

Outlined here are only a few of the most-used methods of applying radium. When it is reflected that it was not until 1898 that Mme. Curie first isolated radium, and not until 1910 that the use of radium for the treatment of cancer was suggested, it is seen that the art is only in its infancy. But even now whole volumes have been written on the subject and the use of radium by the surgeon has progressed far from the experimental state.

## Putting Paper on a Specification Basis

(*Continued from page 375*)

another in opposition to the extensive use of substitute materials. Cotton linters, to the extent of 700,000 bales a year, is available for paper manufacture; and where care is exercised to keep the material free of dirt and cinders a good quality paper results.

LEGAL NOTICES

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

**SCIENTIFIC AMERICAN**

contains Patent Office Notes. Decisions of interest to inventors—and particulars of recently patented inventions.

The use of lime and limestone in the pulp and paper industry is also being carefully scrutinized by the Government scientists in order to develop specifications for lime for the different industries, standard samples and laboratory and plant methods of analysis. Similar tests are under way relating to the restricted use of chlorine for the bleaching of wood pulp. The chlorine in the various kinds of pulp has been materially reduced as a consequence of these experiments without any decidedly deleterious effects on the color of the resultant paper.

### What About Our Wheat Production?

(*Continued from page 376*)

Weld County then began to plant alfalfa as a rotative crop for the celebrated Greeley potato, as they found that the potato yield increased wonderfully when alternated with alfalfa.

Who can deny that the whole problem of refertilization of worn-out grain fields was settled by these farmers of northern Colorado? They not only demonstrated the science of green manuring but they happened to light upon the ideal plant for that important function.

Now I find in handling broadly the question of green-manuring the college professors, and the farm papers, prone to expend their efforts upon diffusive experimentation and discursive discussion. They treat green-manuring as a special process, all by itself, rather than as a part of regular farm routine. They talk about the vetches, cow peas, horse beans, soy beans, etc. If we stop to think a moment none of these is a standard farm crop and if used as an article of green manuring each must be treated specifically, whereas alfalfa is a valuable standard farm crop, and by its use may be utilized as a green manure crop without any break in farm production; that is, no time will be lost in producing a green manure crop, because it is already produced, and may be plowed under any fall and the land seeded to some other crop the next spring.

Another instance of refertilization by means of crop rotation I have recently observed in California: It is the case of sugar beet culture. The culture of sugar beets greatly improves the fertility of the land. Investigations made by the California College of Agriculture showed the following increases in the yield of various crops upon land previously cropped to sugar beets:

Wheat, yield before beet culture, 24.5 bushels; after beet culture, 41.3 bushels; per cent increase, 68.6.

Rye, yield before beet culture, 28.4 bushels; after beet culture, 40.8; increase per cent, 43.7.

Oats, yield before beet culture, 61.8 bushels; after beet culture 75.3 bushels; increase per cent, 21.8.

Barley, yield before beet culture, 23.2 bushels; after beet culture, 43.5 bushels; increase per cent, 87.5.

Potatoes, yield before beet culture, 218.6; after beet culture, 238.0 bushels; increase per cent, 8.97.

Rape, yield before beet culture, 23.2 bushels; after beet culture, 48.8; increase per cent, 110.

Here we discover a natural and easy process of producing our sugar, bread, potatoes, etc., in rotation, and at the same time maintaining the maximum fertility of our soils.

### Why We Need a Separate Trade-Mark Bureau

(*Continued from page 377*)

enabling the utilization of kerosene instead of gasoline in an engine and if so who is the rightful inventor thereof, and in doing so to consider all the fine points of chemistry and physics involved; and immediately afterward to decide whether

"The Security Skylight"

NO higher tribute could be paid to Lupton Rolled Steel Skylight Bars than their selection to protect the great turbines and generators of the Buffalo General Electric Co.

In that huge central station, "the largest steam power plant in the world," every refinement of engineering is used to enable steam to compete with water power. And no avoidable hazard could be permitted to threaten either the investment in plant or the continuity of service.

Lupton Rolled Steel Skylight became the almost inevitable choice for the generating room, because:

*Its thickness and shape stand vibration;*

*It permits the glass free expansion and contraction;*

*No felt or putty is used, hence there is no drying out and leakage.*

The sectional view tells how these results are accomplished. The rolled bar is 1/8 in. thick. The glass is held by strands of saturated, waterproof fibre, and no metal touches it.

There are many places where skylight can be used to advantage. For those, Lupton Rolled Steel Skylight is valuable in proportion to the difficulty of the service. Shall we send Catalogue? Mention Skylight when writing.

# The Price of Bacon

**Some people wonder why the price of best quality bacon is so much higher than the price of live hogs.**

The answer is:

1. From every hundred pounds of live hogs we buy, we get only about 72 pounds of meat and lard.

2. The choice cuts—bacon, ham and pork loins—are only about one-third of the whole animal. They must bring prices much higher than the price of hogs to offset the low prices we get for many of the other cuts. Otherwise we couldn't stay in the pork business.

3. Only about 8 pounds out of every hundred pounds of live hog can be made into fine bacon like Swift's Premium. Only half the hogs we can buy are suitable for this brand; hence **only about 4 per cent of the total live weight of hogs we buy is sold as Premium Bacon.** Other bacon is sold at much lower prices.

4. There is an extra expense of about 8 cents per pound in preparing Premium Bacon, due to careful trimming, curing, smoking, and shrinkage. This extra expense is nearly as much as we get at wholesale for some of the cheaper cuts.

The various cuts not only bring different prices, but changing demands cause these prices to vary with respect to each other. One cut may have the call, with prices of other cuts ranging lower. For example, fancy bacon has been in heavy demand during the summer of 1920, and the price has not fallen with the price of hogs. But lard has dropped about 45 per cent at wholesale and dry salt pork has dropped about 35 per cent.

These prices are utterly beyond our control; bacon may come down at any time, and lard, or some other cut, go up.

But you may rest assured that competition, at all times keen and active, keeps the average return from all cuts down to a point which allows us less than one cent per pound on all pork products sold.

in purchasing a can of olive oil, a housewife might be confused by encountering in the same grocery store cans of olive oil labeled "Sunlight" alongside of other cans of the same commodity labeled "Moonlight."

In practically all English-speaking countries except the United States there is a Trade-Mark Office separate from the Patent Office and a Registrar of Trade-Marks distinguished from and not in any way subordinate to the Commissioner of Patents. Moreover, in the majority of foreign countries, both the Patent and the Trade-mark Offices are a part of the Executive Department corresponding to our Department of Commerce, as for instance in England where these offices are in the Board of Trade and in Canada where they are in the Department of Trade and Commerce.

In connection with the establishment of a separate Trade-mark Bureau and a Registrar of Trade-marks, consideration might well be given to the question of placing in such bureau and under the authority of such official the present function exercised by the Bureau of Foreign and Domestic Commerce, of advising our manufacturers and exporters of the necessity of prompt and adequate protection of their trade-marks abroad, and of how to obtain such protection, and of calling to the attention of trade-mark owners apparent attempts to pirate their trade-marks in foreign countries as noted in foreign trade-mark gazettes, reports from commercial attachés, consular officers, etc. At present, the Bureau of Foreign and Domestic Commerce is handicapped in this work by insufficient knowledge of the ownership and status of the various trade-marks and trade-names; while the Patent Office, because of lack of familiarity with the necessities of export trade and of foreign trade-mark laws and practice, is unable to coöperate as it should in the protection of American trade-marks abroad.

## Twentieth Century Telegraphy

(*Continued on page 378*)

length, although each one sends a separate letter over the circuit, and as the entire operation is automatic there are no variations of any kind to disturb the impartial distribution.

The impulses received at the distant end from the sending distributor pass through a receiving distributor which switches them accurately to the various receiving typewriters. Here the impulses are translated by selector devices into action on the typebars, the result of each impulse being to strike the proper letter on the telegram blank. The two distributors are kept in perfect synchronism, resulting in perfect distribution, by "phonic wheels" or tuning forks. The impulses are caused in the first place by perforations punched in a type by a typewriter keyboard on which the operator "copies" the message to be sent. All this takes place at such a high speed that the capacity of one wire is raised as high as twelve thousand words an hour in each direction.

There are 24 trunk tubes which enter the main office from Market Street. The tubing is of pure copper, which resists electrolysis and chemical action, and also presents an ever smooth surface to the carriers. The longest single tube is one mile in length, the compressed air driving the cartridge message-containers through the tubes at a speed of 40 feet per second. The tubing used is in sections 15 feet in length. Big air compressors operate a combination pressure-vacuum circulating loop system, driving and pulling simultaneously. The tubes are laid with a drainage slope with special equipment for keeping the low spots clear of condensed moisture.

Entering the main San Francisco office are 2,000 wires containing the existing working circuits, spare facilities and provision for growth and extension. These wires terminate in a switchboard, the operation of which is by means of plugs and cords, which enable the various lines to be connected to different sending and receiving positions, to battery sources, etc.

## Taking on Oil a Mile at Sea

(*Continued from page 380*)

the connection made to the hose, six short blasts are blown on the siren of the vessel, this being a signal to "stand by." In answer to these six blasts the shore siren emits similar blasts. Then as soon as the mooring master is satisfied that everything is O. K. he blows one whistle from the ship. This is the signal to start pumping slowly from the shore and is immediately answered by the shore station. As soon as the pumping process has been completed the mooring master signals by three blasts from the ship's siren and the process is brought to a stop. The ship, now loaded, receives her papers, unmoors and gets ready to sail.

The world's largest tank steamer, the "Standard," whose capacity is 118,000 barrels has already been moored in one hour. The pumping was started forty minutes later, and the ship was loaded twenty-seven hours and fifty-five minutes later. An hour after the vessel sailed, making a total time in port of only thirty hours and twenty-five minutes, with an average pumping rate of 4,253 barrels an hour. This particular vessel was never loaded and dispatched in such quick time before.

As a rule, the crude oil is pumped from the shore tanks at its natural temperature. When greater speed in loading is desired the oil can be heated, but the sea water is warm and it rarely becomes necessary to increase the fluidity of the oil to enable the pumps to handle it.

## The Heavens in October, 1920

(*Continued from page 382*)

and rises at 3:20 A. M. in the middle of the month.

Uranus is in Aquarius, and observable all the evening. Neptune is in Cancer, and visible only in the early morning.

The moon is in her last quarter at 8 P. M. on the 4th, new at the same hour on the 11th, in her first quarter at 7 P. M. on the 19th, and full at 9 A. M. on the 27th. She is nearest the earth on the 4th, farthest away on the 18th, and at her nearest approach again on the 30th. During the month she passes near Neptune on the 7th, Jupiter on the 9th, Saturn later on the same day, Mercury on the 13th, Venus on the 14th, Mars on the 17th and Uranus on the 22nd.

At the present full moon a total eclipse occurs, which is invisible from the eastern United States, but partly visible in the western section of the country, and wholly visible throughout most of Asia and Australia. The moon enters the earth's shadow at 7:26 A. M. (eastern standard time), becomes completely immersed in it at 8:29, and gets finally clear at 10:57. From these data it is evident that during the whole eclipse the sun is above our horizon, and the (full) moon therefore below it. But since, in the latitude of 40°, which is taken as the basis of these predictions, the sun rises at 6:30 A. M., local standard time, on the day of the eclipse, it follows that, for points in about the longitude of Chicago, the moon will set just as the eclipse begins, while observers farther west will have a fine chance to see it. On the Pacific Coast, totality will begin well before sunrise, and the spectacle will be of real interest to the early riser.

# FOR YOUR CONTINENTAL MOTOR

## *Three factors which explain the superior results obtained from Gargoyle Mobiloil Arctic*

IF you select a car with a Continental Motor you look for engine results. Continental Motors are the standard equipment today in nearly 200 models of passenger cars and motor trucks.

The most important single factor in the efficient operation of your engine is Correct Lubrication.

The Vacuum Oil Company's Board of Automotive Engineers has carefully analyzed the lubricating requirements of all types of Continental Motors and has determined the correct lubricant to meet these lubricating requirements with scientific exactness.

This correct lubricant is Gargoyle Mobiloil Arctic for all models except the "B-2" and "T" motors that are used in certain models of trucks for which the correct oil is Gargoyle Mobiloil "A."

SOME features of design and the conditions under which Continental Motors operate, influencing the choice of a lubricant, are:

1—Moderately high piston speeds.

2—Close-fitting pistons and well-finished cylinder walls, made possible by expert workmanship and exact production methods.

3—Well-jacketed, vertical cylinders, preventing excessive cylinder wall temperatures.

Taking these points into consideration, together with other important features of design and construction, an oil of the character and body of Gargoyle Mobiloil Arctic is best adapted to provide perfect cylinder lubrication, properly seal the piston rings against gas and fuel leakage, and minimize carbon formation.

In addition to meeting these cor ditions, Gargoyle Mobiloil Arctic is of the proper fluidity to be distributed through the lubricating systems in Continental Motors, providing adequate lubrication for every bearing surface.

With Gargoyle Mobiloil Arctic in your Continental Motor you will secure full power and the minimum cost per mile for gasoline, oil and repairs.

GARGOYLE

# Mobiloils

*A grade for each type of motor*

Domestic Branches: New York Boston Philadelphia Pittsburgh Detroit Chicago Minneapolis Indianapolis Kansas City, Kan. Des Moines

## Chart of Recommendations *for* AUTOMOBILES

(Abbreviated Edition)

GARGOYLE

# Mobiloils

*A grade for each type of motor*

### How to Read the Chart

THE Correct Grades of Gargoyle Mobiloils for engine lubrication are specified in the Chart below.

A means Gargoyle Mobiloil "A"
B means Gargoyle Mobiloil "B"
E means Gargoyle Mobiloil "E"
Arc means Gargoyle Mobiloil Arctic

**These recommendations cover all models of both passenger and commercial vehicles unless otherwise specified.**

Where different grades of Gargoyle Mobiloils are recommended for summer and winter use, the winter recommendation should be followed during the entire period when freezing temperatures may be experienced.

This Chart is compiled by the Vacuum Oil Company's Board of Automotive Engineers, and constitutes a scientific guide to Correct Automobile Lubrication.

If your car is not listed in this partial chart, consult the Chart of Recommendations at your dealer's, or send for booklet, "Correct Lubrication," which lists the Correct Grades for *all* cars.

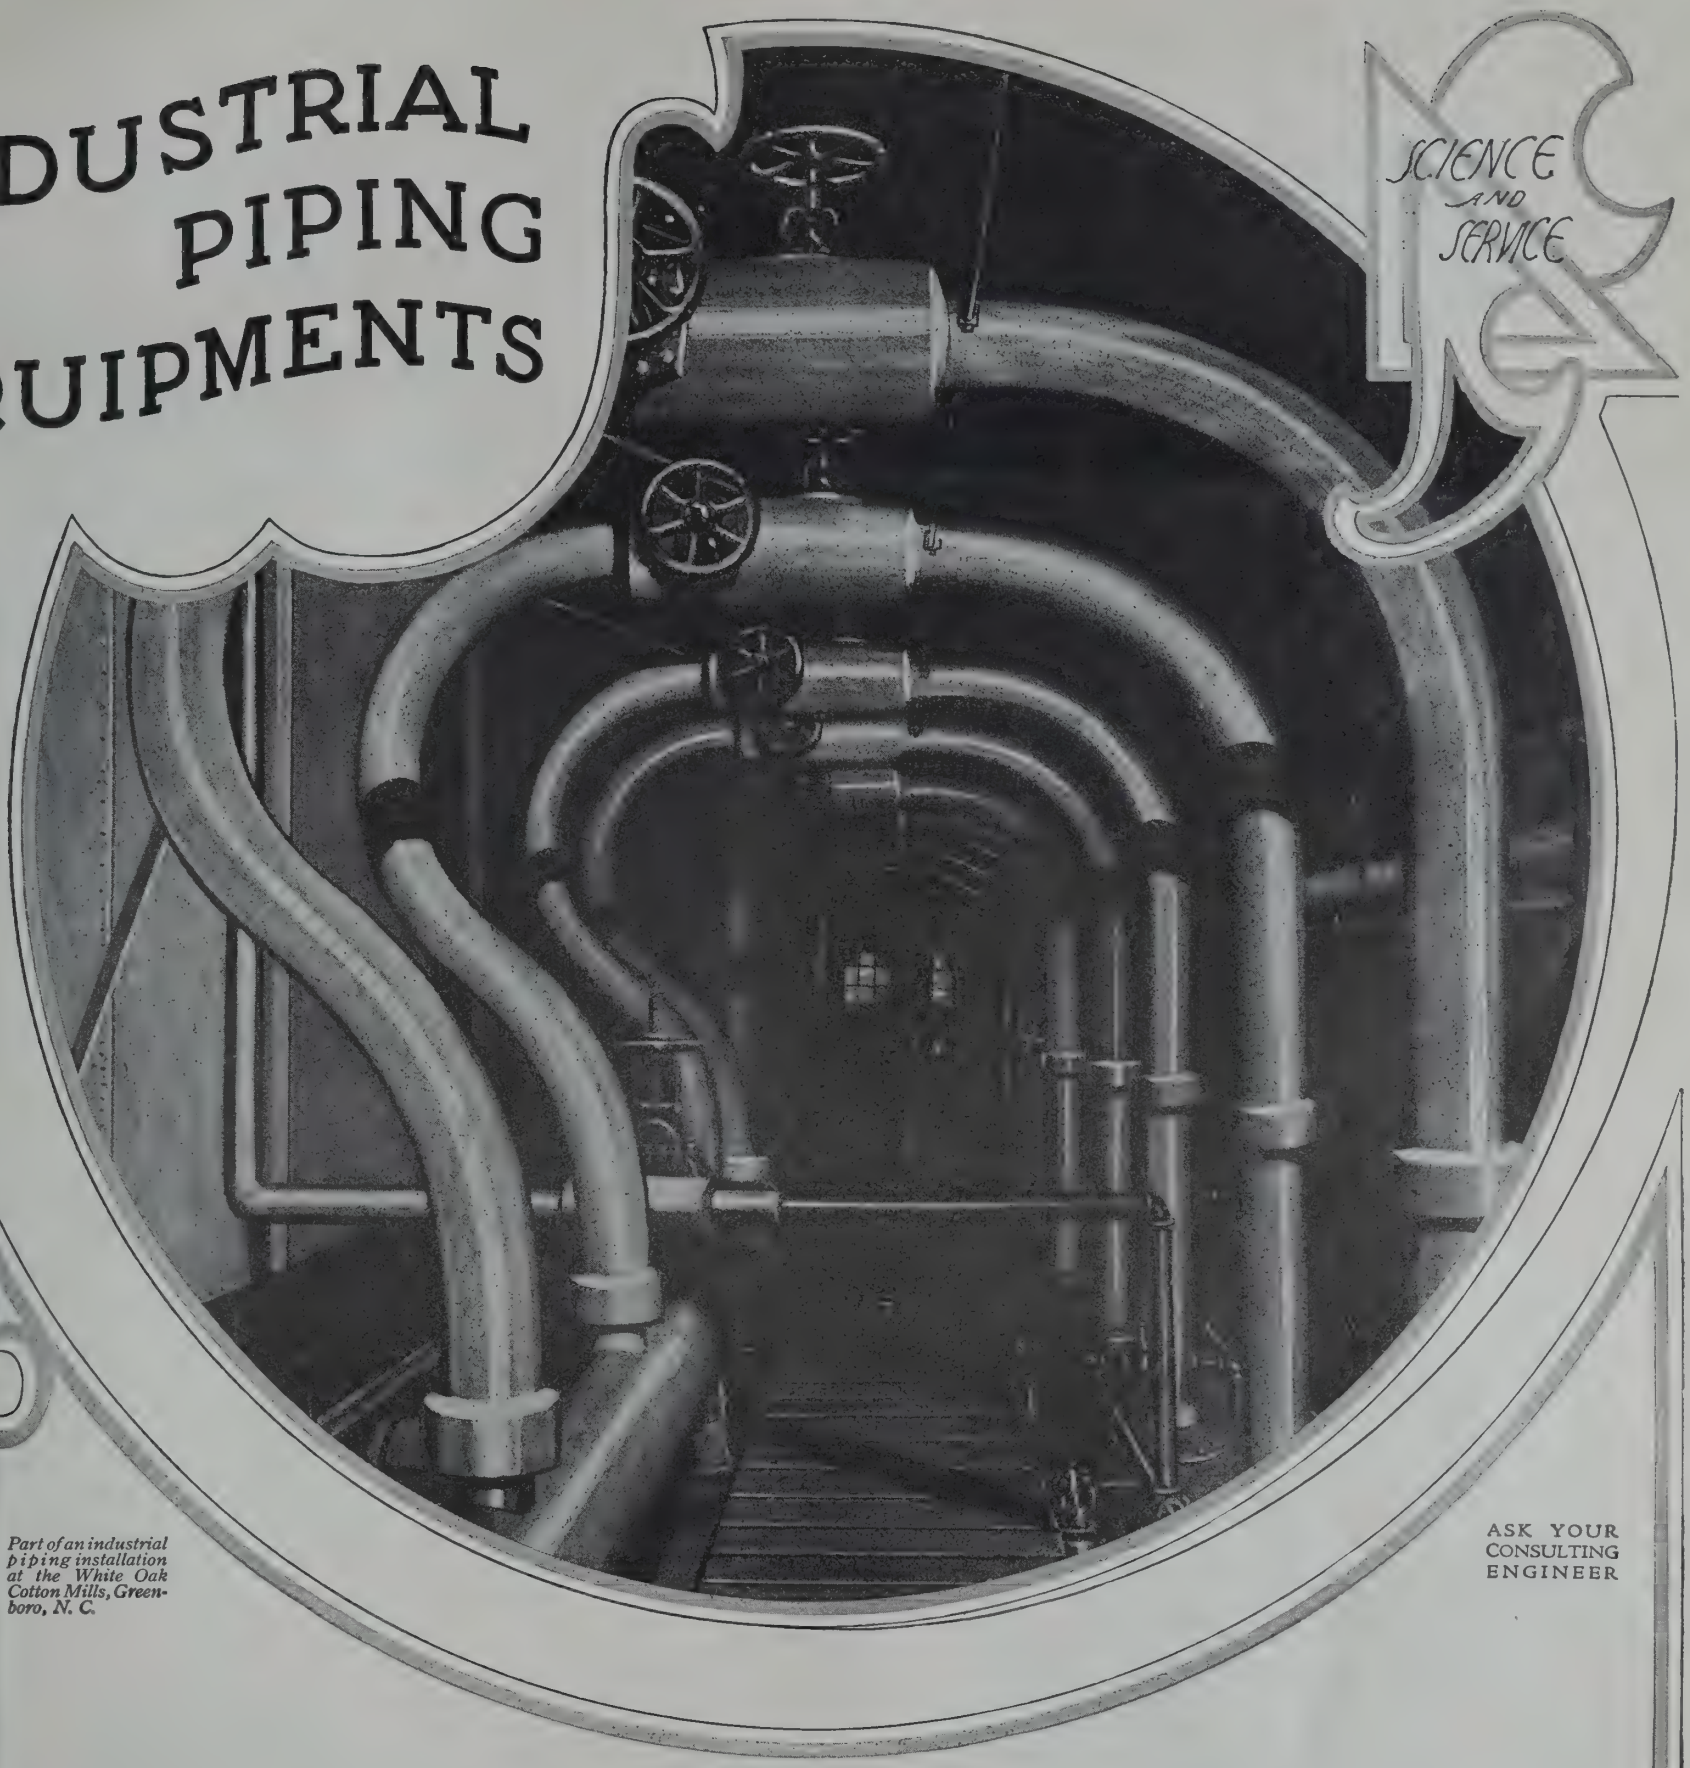
# INDUSTRIAL PIPING EQUIPMENTS



*Part of an industrial piping installation at the White Oak Cotton Mills, Greensboro, N. C.*

ASK YOUR CONSULTING ENGINEER

## Decades of Experience

FOR seven decades Grinnell engineers have been solving the intimate engineering problems that surround the design and erection of industrial piping equipments. Our whole organization has been built up to render a unique service in such work. If you have an industrial piping project of any kind we believe you will find it profitable to consult with us. Our experience covers:

Automatic Sprinkler Systems Steam, Hot Water and Gas Heating Power and Related Piping Process Piping of all kinds
Pipe Bending, Threading and Fabricating Fittings, Pipe, Valves Welding Compressed Air Lines Water Supply Systems Hydraulic Piping
Gordon Dryers Safety Fuel Saver Constant Level Size Circulating Systems Piping for Acids and Alkalies

## *Life on the Ocean— with Electricity at the Helm*

IN the old days before the mast, weighing anchor, pumping ship, and "keeping her before the wind" were tasks for brawny men who knew neither fear nor fatigue.

The old sea was rated in terms of man power, while the new sea is measured in horse power, with electricity as the controlling force. Imagine a great electric city afloat, where tasks are simplified, where safety is assured, and where convenience and comfort are present at every turn. Such is the modern electric ship; the New Mexico or the California for example. Electricity is the source of all things good from stem to stern.

With oil for fuel, a central power plant generates sufficient energy to propel the massive vessel, to furnish light for every purpose, and power for every need. Searchlights, signals, steering apparatus, wireless telegraphy, pumps, capstans, winches, hoists, cranes, drills, welders, rivet heaters, cooking appliances, and a hundred other devices for making work easy and protecting human life—all with one source of power that is safe, clean and *always available instantly*.

Whether at sea or in port, the work of a sailor and the comforts of a passenger are enhanced by the proper application of electricity. Cargoes are loaded and unloaded quickly and efficiently. Repairs are facilitated, and the ship is kept in active service over longer periods, thus aiding commerce and world distribution to a marked degree.

Such a development has not been simply a question of designing and building the necessary equipment for marine electrification. It has devolved upon some manufacturer to look well into the future and visualize the needs aboard ship, and then to engineer the machinery into those needs. In this capacity the organization, experience and facilities of the General Electric Company are serving the American Navy and the American Merchant Marine.

## Transportation in the Oil Fields

**By Edmund Conaway**

IN the great oil fields of the country there are many different forms of transportation. In the mountainous districts of the country most of the hauling within the fields is done by teams, while within the more level country it is done by trucks, tractors and caterpillars. I do not mean to leave the impression that no teams are used in a level country, because in a great oil field there is plenty of hauling for all. In the great fields of the Southwest there are thousands of teams and trucks. I remember one day having passed seven hundred teams upon a road connecting two towns, thirty-five miles apart. One of these was a shipping point and the other was the center of a large oil field. Upon this same road were many trucks, also tractors and caterpillars. In good weather trucks are always busy and occasionally some teams are idle on this account, but in bad weather the teams do the greater part of the hauling.

Trucks and trailers of every make are used. It is a common sight in Central Texas to see a tractor pulling a boiler and two wagons loaded with casing. The expense of transportation is greatly due to the distance material must be hauled and to the bad roads. It is estimated that where the depth of wells is at least 3,200 feet the cost of hauling material by teams and trucks will average $8,000.

The roads throughout the oil fields of the Southwest have been very bad. At times the only hauling that can be done is by horses, mules and oxen, and often but few teams will venture out. In traveling upon the main roads it is a common sight to see trucks, cars of all makes and wagons stuck in the mud. Ordinarily trucks and teams travel together in order to help one another. Upon one occasion when a driver with four mules got stuck in the mud, it being almost dark with no help near, feeling that his animals were safe he went away and staid until morning.

One man is not bothered by bad roads—the owner of the airplane. A few wealthy men of the West and Southwest visit their holdings in this manner. At Casper, Wyoming, last summer an agency was established to sell airplanes to wealthy oil and cattle men.

These great trucks and tractors are extremely hard on roads. In order for one to have some idea of the roads either in dry or wet weather it is necessary to travel over them. In dry weather they are extremely rough and in wet weather they are lakes of water and mud.

The streets are often excellent examples of the muddiest oil field roads, due to much heavy hauling and rain. In 1919 there was a great deal of rain. I have often seen a team stall on the main street in oil towns and horses and mules down in the mud. In one instance I saw a mule down in a mudhole in front of the railroad station at Ranger.

Gum boots are very popular among men and women. In Ranger in order to cross the streets a form of sled was devised pulled by one horse. These were stationed at different corners and anyone could be set across the street for a dime.

Many mules and horses are used in the oil fields of the Southwest. The care and treatment of animals there is poor as compared with that given in northern fields. They are fed enough, but are given little thought as to shelter, grooming and bedding. What grooming the animals receive is given with a whip.

## The Gordon-Bennett Airplane Race

ALTHOUGH the failure of the special American racing machines to be placed in the recent Gordon-Bennett Challenge cup race in France was a keen disappointment, there are several outstanding lessons to be learned which, if laid to heart, should enable us to win, or at least come very much nearer to victory, in any future international contest.

The outstanding fact is that, as compared with the winning French machines, our own were comparatively untried, or, to borrow a yachting term, they had never been properly "tuned up." In commenting on the recent America's Cup contest, we emphasized the fact that until "Shamrock" met "Resolute," she had had no opportunity to test herself against an up-to-date racing yacht of her own type. Everyone knew that she was fast, but just how fast she would be over the Sandy Hook course against a yacht that had tuned up in American waters was not known. The American defender, on the contrary, had gone through three seasons of exhaustive trials against a yacht, the "Vanitie," which was just about as able as herself.

Similarly, when the three American machines started in the Gordon-Bennett race, they were not only flying around a circular course with which they were quite unfamiliar, but they found themselves matched against French machines that were thoroughly at home on the course and knew exactly what they could do in hugging the many turning points by resorting to steep and all-but-vertical banking. It is probable that, on a straight-away course, the American racers were faster than their French and British competitors; and had they been thoroughly well tuned up and had the course been a straight-away, we think that they would have won. But flying with the engine wide open on a straight course and flying at full power and speed around a circular course are two very different things. At a speed of approximately 170 miles an hour, it takes skill, familiarity with the turns, and absolute confidence in the strength of the wings, to make a close turn.

It is a noteworthy fact that all three of the French contestants were biplanes of a standard type, engined with standard motors. The only direction in which they departed from normal was that they carried somewhat less wing surface than the standard military machines. The winning Nieuport covered the three laps of the 300-kilometer course at a speed of 168.4 miles per hour, which is a long way below the 200 miles an hour which was freely predicted as the speed of our own and the French machines.

The three American contestants were described in our issue of September 11th. The most powerful was a Verville-Packard biplane, equipped with a 500-horse-power Liberty engine. The other two were monoplanes —a Curtiss machine equipped with a 400-horse-power engine, and a Dayton-Wright monoplane with retractable landing gear, equipped with a 250-horse-power engine. All three machines were credited with having made 200 miles an hour and over on straight-away flights. In each one, weights had been cut down to a minimum, and wing surface had been reduced to the lowest possible figure consistent with safety. None of the machines was equipped with shock absorbers in the landing gear, and all of them, because of the great engine power in proportion to wing surface, had high landing speeds.

It was these features which cost the Curtiss monoplane dearly, because when making a landing the gear, unable to stand the impact, crumpled and the machine was wrecked. The Verville-Packard biplane was put out of the race early by engine trouble, the result, it is said, of overheating due to radiator failure. The beautiful little Dayton-Wright monoplane had to come down because of failure of the steering gear, one of the rods, according to the pilot, having become bent and the machine being out of control. It is possible that, at the very high speed developed, the nascelle proved to be too short to allow of a free flow of air to the rudders, or, to put it another way, the latter did not possess sufficient area for satisfactory control. This last, however, is mere conjecture.

It should be understood that what we have said above is not at all to be considered as excuses for our failure. The flying field was a representative French flying field and the difficulties of landing and taking off were alike for all.

## Einstein Contest Information

INQUIRIES about the Einstein contest having brought out several points not completely covered by the published rules, we take this opportunity to make these points clear.

The greatest concern seems to be about the precise style in which words are to be counted. Compound words, when properly used and hyphenated, will count as single words. Algebraic expressions standing for single numbers or ideas will likewise go as single words. This applies to the single letters $x$, $y$, $z$, $t$, etc., when used singly; also to such items as the functional notation $F(x, y, z, t)$ and the radical giving the value of the Einstein correction factor. Under this convention equations will count as three words—one for each member and one for the sign of equality. If mathematical notation is employed which seems to the Einstein Prize Essay Editor to fall under neither of these specifications, he will use his best judgment in applying the spirit of the convention that a word stands for an idea.

The main title will of course not figure in the word-count. But some contestants will wish to use a sub-title, sub-heads scattered through the text, etc. In view of the fact that every competing essay is a prospective contribution to the SCIENTIFIC AMERICAN, it seems proper to set our own typographical style as a standard. Sub-titles must go in on a single line of a three-column head, as seen on page 398. A sub-head may occupy no more than two lines of a single column, as seen, among other places, in our monthly articles on the Heavens; and sub-heads should average more than 500 words apart. Subject to these requirements, sub-title and sub-heads may be used and will not figure in the word count. Such fixtures when longer than thus contemplated will be counted in full, on the theory that they have been used to relieve the text of part of the story.

Many contestants will desire to illustrate their text with drawings, diagrams, etc., which may require captions. These will be regarded as part of the picture and will not be counted, unless it appears to the Einstein Editor that they have been used to relieve the text. The best way to meet this possibility is substantially to duplicate the caption in the text; but we offer this as a suggestion, not as a requirement. When the spirit of the law is violated the entire caption will be counted as part of the text.

Anything whatever in the nature of a preface or prolog, an appeal to the judges, an apology for or statement of the viewpoint of the essay, whether intended to be printed as part of the essay or not will be considered as part of it and included in the word count.

The point has been raised whether a single competitor may submit more than one essay. We know no reason why he should expect such diffusion of effort to work to his advantage, but if he does not agree with us, we shall have to allow him to submit as many essays as he pleases. We will not open the envelopes giving any name and address until after the award of the prize; so we will not be aware of multiple efforts and could not rule them out if we would. We must require, however, that when one man submits multiple essays he submit a separate identifying envelope with each, and sign a different pseudonym to each.

A few suspicious souls have asked how they can be sure that their essays reach us, since registering the package involves writing on it the name and address of the sender. Such registration is not contrary to the rules; the outer wrapper is destroyed as soon as opened, leaving no record of the sender's identity. If you do not credit us with good intentions to this extent you would best stay out of the contest.

A very delicate question has been raised by several eminent gentlemen who have already appeared in the public prints on the subject of relativity, and who wish to know whether they may use parts of their own previously appearing work in their essays. Our whole impulse is to say "yes," but there is an operating detail which almost forces us to say "no." The essays will go to Professors Page and Adams anonymously. Any material use of previously published matter will hardly escape them, for they may be assumed to be familiar with the literature. In the event that they recognize the old material, they must conclude either that the essay using it is by the original author, which would destroy its anonymity, or that the passage has been deliberately appropriated by another, which would bar the essay even if quotation marks and acknowledgment of source were employed.

It may be necessary to supplement the last paragraph with a word of reassurance. Where words are property, ideas are not. No contestant need fear to incorporate in his essay an idea which he has found in a published book or article, if he gives it new form in his own words. But direct quotation, even with acknowledgment, unless it be of a mere catch phrase, will not do.

## Doubling the New York Subway System

DEARLY bought experience has shown the need for faith and foresight in providing for the future transportation requirements of large cities. This is true both of the authorities and of the public. It was the lack of clear vision and courage that so greatly delayed the commencement of the New York subways, and we are suffering the penalty of that irresolution in the present intolerable congestion of our subways. We did much better when it came to the question of doubling our facilities by the construction of the so-called Dual System; but the astonishing way in which the new lines were crowded with passengers within a few days after opening proves that, even then, we did not look far enough ahead and that we failed to perceive the accelerated rate at which subway travel was advancing.

There is nothing of timidity, however, in the bold plans for enlarging our present subway system to meet the demands of the future which the Transit Construction Commissioner has recently published. Additional trunk lines are to be built running north and south under the avenues, and these are to be associated with crosstown lines, the whole new system being located with a view to rounding out and relieving the existing system.

It is gratifying to note that on some of the proposed crosstown lines, use is to be made of the continuous moving platform. This admirable device proved its great passenger-carrying capacity as long ago as the date of the Chicago Exposition, and we believe that it will prove to be admirably adapted for a rapid distribution of the crowds which will be unloaded at certain transfer points from the north and south subways. There is no known or conceivable method of local transportation which competes with it in its flexibility and in the number of passengers that can be carried within a certain time and within certain restricted distances. The moving platform, of course, cannot compete with a fast express service; it is not intended to. But for local service it is unsurpassed, and we hope that the conservatism and lack of vision which prevented its adoption when the last addition was made to our subway service, will fail to shake the Transit Construction Commission in its determination to include one or more moving platforms in the contemplated enlargement of the system.

# Forty Centuries Ago—And Now

## Why Should We Not Make Paper Again from the Papyrus?

By M. Tevis

IN the present world-wide shortage of paper it is not strange that in the search for new materials some attention should be paid to the remarkable plant which was first employed for this purpose and from which paper takes its very name. The papyrus reed or *Cyperus papyrus* was first used in Egypt, for the making of paper. The Egyptians in fact made many uses of this remarkable plant growing in the shallow waters of the Nile. The main root of the plant, which is about as thick as a man's wrist, lies in a horizontal position, while smaller roots extend downward from it into the mud and the stem rises into the air. These stems are triangular and tapering in shape and bear a picturesque tuft or umbel at the top which was compared by Pliny to a thyrsus, the crowned and garlanded staff borne by devotees of Bacchus in their revels.

This tufted head was used for the making of garlands wherewith to crown the images of the gods and wreathe their shrines. The root was used to make various utensils as well as for fuel. The pith contained in the stem was a common article of food both raw and cooked. The great value of the plant, however, lay in the stem; this is commonly six to ten feet long and a recent British investigator declares that along the upper Nile, where the plant still grows, though it is now extinct along the lower Nile, the stems often exceed fifteen feet in length. From this stem not only writing material was made but also cord, rope, and cloth, mats, sails, and boats. A certain piece of sculpture has been found belonging to the fourth dynasty, in which men are shown building a light skiff with stems cut from a neighboring plantation of papyrus. Some authorities indeed believe that the bulrushes mentioned in the Bible were really papyrus plants.

For the purpose of making paper the triangular stem was cut into longitudinal strips, those from the center of the plant being the broadest and most valuable. These strips were placed side by side on a board, forming a layer of suitable width, which was then covered with another layer of shorter strips laid at right angles. The sheet thus formed was soaked in the waters of the Nile, which caused the two layers to adhere firmly to each other, probably from deliberation of some sort of glutinous matter in the substance of the stem itself. The sheet was then pressed and dried in the sun, afterwards being polished with oil of cedar by means of ivory or a smooth shell. To form a roll the sheets were joined together with paste (glue being too hard).

The use of papyrus spread from Egypt to Greece and Italy and thence over Europe; it was finally superseded by vellum but did not entirely disappear until about the twelfth century.

Of recent years the papyrus plant has been freshly studied by English, French, and German authorities. In a late report made by certain British investigators it is stated that for a distance of three hundred miles along the upper Nile, it is at times exceedingly difficult to keep the main channel clear because of the enormous quantities of papyrus and other water plants which choke it, while all the tributary streams in this region are blocked for many miles. This dense vegetation is known by the general name of "sudd," and experienced observers estimate that it covers not less than 5,000 square miles, forming an immense store of valuable material either for fuel or for other purposes. It is estimated, indeed, that there is a store of 144,000,000 tons of sudd in this area. Employed as fuel this would be equal to 28,000,000 tons of coal and would be capable of yielding an amount of horsepower equal to about three-fourths of the theoretical average power of Niagara Falls.

But this material is also capable of yielding rope fiber and paper pulp, while the ash contains so much potash as to form a valuable fertilizer. Crude paper pulp, known in the trade as "half stuff" is readily obtainable, according to experiments made by an English chemist, by heating the papyrus stem either green or dry under pressure, to about 150 degrees Centigrade with water alone, no caustic soda or other chemicals being required. The air-dried papyrus yields about forty per cent of dry "half stuff" and about twenty per cent of dried bleached pulp. The paper made from this pulp is of very fine quality. Still more recent research at the laboratory in Khartoum shows that papyrus stems, when treated with hot water, under a pressure of about four atmospheres, yield practically all their mineral matter and most of the protein to the solution, while the residue constitutes very satisfactory crude paper pulp.

According to French students of the same subject papyrus pulp is very fine, slightly resembling that made from alfalfa. The fibers of the papyrus are regular and cylindrical and very fine and short, having tapering ends and a central canal one-third the width of the fibers. There are immense fields of papyrus in the French colonies of West Africa, especially in the delta of the Congo, and it is believed that when there are sufficient facilities in the way of railroads and labor, this material will be drawn on heavily.

### Saving Wear on Shoe Soles

To the Editor of the SCIENTIFIC AMERICAN:

I note in your issue of July 31 last an article relative to a process for saving wear on shoe soles. I think I can go the writer one better by suggesting that copal or dark varnish be used in place of vaseline or oil. Apply as many coats as soles will soak in. Have found that this will make the soles outwear the uppers.

Old Mystic Ct. W. H. F. HANKS.

### The Horizontal Rainbow

To the Editor of the SCIENTIFIC AMERICAN:

I recently noticed a phenomenon of light while flying for which I do not derive a satisfactory explanation. I will be pleased to learn the proper explanation from yourself or from a reader of the SCIENTIFIC AMERICAN.

The phenomenon consisted of a rainbow in the form of an ellipse, a rather elongated ellipse. It occurred while I was flying around a small rainstorm and showed up on a low hanging mass of rain and water vapor some two thousand feet below me; it, of course, moved as I moved in the plane, and remained very bright for some two or three minutes. To give the details of the light direction I will mention that it occurred in the latter part of June about three o'clock in the afternoon in the latitude of Houston, Texas. I was flying in an easterly direction and the major axis of the ellipse seemed to lie in a line pointing a few degrees east of north, the ellipse lying to the north of my path, and as nearly as I was able to estimate it the shadow of my plane fell on what would be the southern focus, i. e., the focus nearest the plane, the red end of the spectrum being on the inside.

I trust that this may be of interest to some of your readers and thank you in advance for any light which you or they may be able to throw upon the phenomena.

RUFUS RIDDLESBARGER.

[*This is a case of the horizontal rainbow, formed by a more or less horizontal sheet of water drops below the level of the observer's eye. Such bows are seen upon a layer of cloud from a mountain summit or from aircraft, but those that have heretofore been observed and discussed in detail have generally been seen over bedewed fields or a thin sheet of fog near the ground or water, or in droplets deposited on a layer of oil floating on the water. The horizontal bow is circular only when the sun is overhead; at other solar altitudes it is elliptical, parabolic or hyperbolic. This feature is well explained with a diagram by Dr. Otto Klotz in the Journal of the Royal Astronomical Society of Canada, September,* 1917, *p.* 294 *ffg. Another explanation appears in Nature, March* 1, 1916, *p.* 5. *A résumé of several observations of horizontal rainbows appears in the Monthly Weather Review (Washington, D. C.), Feb.,* 1916, *p.* 65.—THE EDITOR.]

### Protecting Trees from the Sun

To the Editor of the SCIENTIFIC AMERICAN:

In a recent issue I noted the article regarding the desirability of protecting trees when transplanted from the effects of the hot sun. This has been known and the practise of protection systematized here, the common usage being either to loosely wrap the young trunk with a heavy grade of wood veneer tied with wire, or to nail a couple of six-inch boards into a V-shape and to drive these down a couple of inches from the tree so as to permit of ventilation while protecting the bark from the southwest sun. These schemes are both inexpensive, easily applied and readily removed when the tree is established.

St. Louis. A. BLAIR RIDINGTON.

### Metering Liquids

To the Editor of the SCIENTIFIC AMERICAN:

In a recent issue you carried a description of a "device for measuring the flow of liquids," stating that this was put out by an English firm. This description appears to be of an instrument which has been manufactured for the past ten years by my firm, and which has found wide application not only in the field of water measurement, but in the chemical industries and in the manufacture of paper as well. I hope you will agree with me that in fairness to our company you ought to make this clear to your readers.

Philadelphia. L. G. CHASE.

### Saving Gas

To the Editor of the SCIENTIFIC AMERICAN:

Your timely editorial, "How Many Miles to the Gallon?" in your issue of September 4th, if answered by many drivers who are making good mileage, telling how they do it, might lead to economizing results both in driving and in making autos. I have been trying out an idea, not a new one by any means, and the result has convinced me that at least one kind of carburetor is wasteful of gasoline, and also that there should be an authoritative test of all carburetors, and all condemned that do not come up to a certain standard. The idea referred to is the admission of air to the manifold for which purpose I use a quarter-inch pet-cock with a rod connected to same and extending through dash, giving control of amount of air admitted from driver's seat. My car when running on the leanest practicable mixture with pet-cock closed, will reach its greatest speed with cock about half open, but for runs of any distance I enrich the mixture a trifle and keep the cock wide open, and am making 30 miles to the gallon—short runs excluded—over country roads and about half of them sandy; more than 50 per cent better than I could do before. On rough country roads and city streets the cock is kept closed; with it wide open the engine will not work well when running slow.

The gas pressure in the manifold of an engine running at fair speed is much below atmospheric pressure resulting in a suction on the carburetor intake which effects the feed. When the engine slows down that suction and the inflow of gas are decreased to the point where, when mixed with the inflowing air from the pet-cock it becomes too lean to fire properly.

The increased power I get is probably due both to better evaporation and to the expansion of the air heated in the cylinders by the burning gas, and that leads to the idea that some day air may be used in gas engines to a much larger extent than at present. The air may be admitted and compressed in the cylinders as the gas is now and the burning gas admitted at the moment of ignition from a separate chamber. And then there is dust many kinds of which under right conditions are powerful explosives, and such conditions should not be difficult to provide in gas engines.

I witnessed the results of the flour mill explosion in Minneapolis in 1878, and since have had considerable respect for the potentialities of dust.

Caldwall, Ida. H. W. STONE.

### To Einstein Prize Essayists

To the Editor of the SCIENTIFIC AMERICAN:

I have in my possession a type-written lecture of recent date given by a German scientist on Einstein's principle of relativity. The lecture is supposed to be a popular one, although it is not free from mathematical formulas. It was held before a group of technical engineers in one of Germany's largest industrial plants. I am willing to loan it to any of the competitors for the Einstein prize essay who is able to understand German, on condition, of course, that the lecture be returned to me in due time.

Bowman, N. D. CHAS. BACHER.

# Concrete and the Building Crisis

## Some of the Advantages Which Have Led to Wide Adoption of This Structural Type

By Robert G. Skerrett

STRUCTURAL concrete bids fair to be our industrial salvation in the erection of loft, office, and factory buildings. The housing situation for many of our indispensable activities has reached an acute stage, and we are likely to be hampered for some years to come unless we can provide quickly and at a reasonable cost proper accommodations for our business, our productive, and our administrative enterprises of various kinds.

Building materials of more familiar kinds are high priced and difficult to get with any dispatch, deliveries being more or less uncertain; and skilled labor of all classes is exceedingly expensive and likewise hard to obtain. Nevertheless, no one wants to put his money in a building that falls in any way short of accepted structural standards. Happily, there is a solution for the problem.

Reinforced concrete no longer involves physical uncertainties. The technique of mixing has been reduced to definite formulæ suitable to divers needs. The qualified builder knows today that he must make certain that neither his aggregates nor his sands contain injurious vegetable or other organic matter, and tests are prescribed which enable him to determine this. In the same manner he understands that he should use water that is clean and free from oil, acid, alkali, or vegetable substances. He has learned that the measure of water in the mix bears directly upon the utlimate strength of the concrete and also determines the time that must elapse before his molds may be removed. Finally, experience has taught him that his reinforcing metal should subscribe to standard specifications and be free from excessive rust, scale, paint, or coatings of any character which might tend to reduce or to destroy the bond between the steel and the enveloping concrete.

Failure to adhere to these requirements by people who have rushed into the field of concrete construction without proper training explains the disappointing results that have occurred from time to time. Today the established companies engaged in this branch of engineering go forward with the same confidence that would follow the use of other materials.

In a number of our populous centers it is essential that there be reared as quickly as possible some scores of buildings of the loft type, ranging anywhere from six to twelve stories in height, in order that the most can be made of the ground area available; and an analysis of existing conditions in the labor and material markets reveals that these demands cannot be met speedily unless concrete be employed.

An office building that brings out the artistic possibilities of concrete

This huge structure, 200x331 feet, covering an entire square, is representative of the best concrete factory design

**Two concrete buildings of different types now going up in New York**

*THE expansion of industry and the concentration of business enterprises in our centers of population have brought about a real crisis. Structural materials and skilled labor are hard to obtain in sufficient quantities to rear the buildings that are sorely needed. In this situation reinforced concrete bids fair to provide an ample and a ready relief. The reasons for this are broadly covered in the accompanying article, but emphasis is given this presentation by an analysis of costs of the structural frame for a 10-story loft building, in different types of construction:*

*All reinforced concrete, $1.50 per square foot.*

*Reinforced concrete except that steel cores are used in both exterior and interior columns, $1.90 per square foot.*

*Structural steel with terra cotta or cinder-concrete floor arches, $2.50 per square foot.*

*Contrary to the belief entertained by the uninformed, the adoption of concrete does not entail dampness, difficulty of making changes, or any uncertainty as to safety.*—THE EDITOR.

The strength of a concrete structure is largely dependent upon the disposition and the dimensions of the supporting columns. In buildings up to twelve stories in height, a suitable concrete column of circular section to do the work of a 20-inch-square steel column would have a diameter of approximately 34 inches; such a concrete column might be properly designed to carry a live load of 150 pounds. Of course, there are at times objections to surrendering so much floor space to the larger cylindrical concrete columns, but this difficulty can be offset by substituting on the lower floors smaller concrete columns strengthened by cores of either steel or cast iron. Naturally, as each added story is reached the weight to be borne diminishes, and all-concrete columns of lesser diameters answer on the upper floors. A concrete skeleton building, even when having steel or iron-cored columns, will cost considerably less than a steel structure of like proportions. The adoption of the more expensive columns would hinge, of course, upon the rental value of the floor space saved.

The thickness of concrete floors for a specified load varies according to the distance between the columns. In order to obtain the needful girder strength, the floor thickness is greatest where the span between the columns is longest; and the factor of safety commonly allowed by competent designers has proved on many occasions equal to a much greater burden. For instance, floors of the girder-beam-and-slab type, intended for a load of 200 pounds to the square foot, were found capable of holding up under an average weight of 900 pounds; and another floor of the flat slab type, for which the prescribed load was also 200 pounds, did not fail when the burden reached more than 1,200 pounds. Concrete girders having a 50-foot span are carrying right along floor loads of 500 pounds to the square foot.

The monolithic character of reinforced concrete buildings admirably adapts them to resist the vibration which might otherwise be set up by rapidly moving machinery; so mechanical equipment can be held rigidly to the floors and run at higher speeds. Factory work can thus be permitted in structures where the other tenants might be seriously disturbed if vibration existed.

In Greater New York, nearly every loft and office building has granolithic concrete floors. Those that are not so fitted have wood floors; there is no structural or economic difficulty involved in this detail, the choice being determined mainly by willingness to pay the difference in cost. For the sake of finish, some owners prefer brick curtain walls, but this often involves a sacrifice of floor space. An 8-inch concrete wall is claimed to be as tight as, if not tighter than, a 12-inch brick wall; and there is rarely any trouble with concrete walls even though they have not been waterproofed in any way.

The reinforced concrete structure of the loft type saves money inasmuch as the interior walls and ceilings need no plastering except in the entrance halls, etc., where a certain meas-

**The early appearance of the huge concrete building of an electric company in New York, showing the emplacement of column molds and the work of laying concrete and erecting forms on the ground floor**

e of decoration is desirable. The adaptability of the ncrete loft structure is well brought out where it is ared adjacent to old buildings. In such circumstances is possible to place the wall columns from four to six t inside the external lines, carrying the exterior walls cantilevered floors. On narrow city lots this charac-istic might prove a highly important factor.

As time is of the essence of the present situation, the eed at which concrete buildings can be erected is of pment. On the average, from the time decision is ade to start work a concrete building can usually be npleted at least as quickly as a typical steel struc-re of the same dimensions. And carefully prepared tail estimates show in numerous cases a saving of per cent over steel where structural concrete fram-g is employed; while the total saving on the com-eted and outfitted structure often averages quite 20 r cent. All this is well illustrated by a building w going up in New York City and covering an area 331 x 200 feet.

A ground plan of such magnitude, filling in fact, a ole square, requires the movement, distribution and placement of large quantities of materials during various stages of construction. Reinforced concrete ll be used throughout with the exception of a brick neer on the exterior walls. Here we have striking dence of the benefits of mechanical equipment for handling of essential materials. To begin with, re are centrally located in the basement two power-ven mixers placed directly beneath the towers of o gravity plants for the delivery of concrete any-ere within the building area. The sand and gravel e dumped at one side of the site from the street el into a bin from which the premixed stuff is rried by a belt conveyor to the middle of the cellar d there transferred to two smaller conveyors running right angles. These drop the aggregate into bins se by and the latter feed directly into the power xers. Attached to each bin is a hopper of a scribed capacity, and the attendant worker has only raise a vertical sliding door to release the desired ount of the sand and gravel. Similarly, from the jacent platform, just enough cement and water are asured and dumped into the mixer to make up a bic yard of concrete. The mixer delivers the con-te to a hoist bucket, and every minute it is possi-to raise a load to the desired height, dump it into tower hopper, and send it by gravity down the e of chutes to any point between the base of the ver and outward within an operative radius of 160 t. In this way, the two towers can handle two bic yards every 60 seconds. No trouble is experi-ced in thus placing, during a working day, quite 700 bic yards of concrete.

The counterweight chutes, supported by steel booms, rmit the utmost flexibility. The distributing system es not clutter up the floor in any manner. There e no trestles or runways to interfere with workers gaged in other parts of the undertaking. The con-te can be delivered as fast as the mixer can pre-re it and as soon as the forms are ready to receive The equipment saves in unit labor costs because e hoisting engine and gravity take the place of the n otherwise required to wheel the concrete from the int of mixing to those of deposit. The amazing ature about up-to-date work of this sort is the many ngs of various kinds that can be done simultaneously thout causing confusion. A little analysis reveals at this would not be possible but for the mechan-l facilities employed in mixing and in distributing

**Measuring the strength of a leather strap**

## Testing Ropes and Straps

HOW strong are the stirrup straps used on your favorite riding horse? Are the traces used in pulling farm machinery equal to the task? And, figuratively speaking, is the rope strong enough to hang a man? Such questions can be answered by a machine perfected by the Bureau of Chemistry, United States Department of Agriculture, which is capable of testing the tensile strength of fabrics, textiles and harness leather.

For instance, if you wish to know the strength of the belt you wear on your clothes, put in motion the one-and-one-half horse-power motor in the laboratory of the Bureau, thus starting the tensile machine. Different weights are applied to the pulling lever, the apparatus operating from a pivot near the top along graduating scales, one of which automatically records the pulling power necessary to break a given piece of textile, fabric or harness leather. Our illustration shows the general ensemble of the machine, and suggests quite clearly the manner in which the leverage necessary for the test is brought to bear in increasing measure until failure occurs.

The object under test is gradually given all the load it will bear, the machine automatically registering the stretching strength of the object up to the breaking point. The apparatus is not only valuable for determining faulty textiles, fabrics and harness leather, but the data can be applied in drawing up specifications in manufacturing material of substantial tensile strength. It is said to be the largest machine of this character in use.—By *S. R. Winters.*

## Piling Up the River Bottom Into a Dike

MARK TWAIN, in one of his most amusing veins, described the disease which might be named Mississippitis. It consisted in a violent attack of emotional insanity in connection with one or another of the projects afoot for the improvement of the valley of this great stream. But the peculiar part of the thing was that it never affected any two people exactly the same. Where one maniac would range over the country in the cause of dredging a channel of ridiculous depth from the Twin Cities to the Gulf, another advocated with equal ardor the filling of the river so as to make the water scour out its own navigable pathway. Where a third enthusiast was booming the construction of vast works to prevent floods, another was distributing propaganda looking toward the expenditure of millions of dollars for large reservoirs in the upper parts of the Mississippi drainage basin to prevent the recurrence of low water.

The great humorist does not tell us so explicitly, but it is a fact that he could depict such a variation of opinion as to what ought to be done to the Mississippi, merely because the problem presented by the river does actually vary most widely from season to season and from year to year. It does carry its flood levels to destructive heights, and it does go down, in its dry season, to a point that is destructive to interests that depend upon a reasonably full river. It does call for treatment of the most divergent character, and does confront the engineer with directly contradictory requirement. And while a good many of its vagaries have been successfully dealt with, some remain.

But today the Mississippi is not alone in puzzling the engineer through the apparently irreconcilable nature of the problems that it presents. California has a river—the Sacramento—that goes to equally violent extremes, and calls for equally contradictory measures in its control. And here there is an additional complication not present on the Mississippi. The State of California is interested, more than anything else, in the volume of irrigation water that it can get out of the river. But the Federal Government steps in to say that the river is a navigable stream, and must be treated and conserved as such. Accordingly the engineers must so handle the river that there shall be enough water for the irrigationists, and enough left over after they are through with the stream to float the ships which carry their products to the markets.

The whole problem really resolves itself into one of flood control. When this is properly handled, the subsidiary problems of irrigation and navigation will have been resolved. And, as our photographs show, the control of the spring flood waters is being undertaken in a rather novel way.

The problem centers in the so-called delta—a region of flats under low water, which has been built up by the deposits from the periodical floods of the centuries. The treatment consists in diking—but the distinctive feature is the manner in which this diking is carried out. It happens that the material from the bottom of the river in this section is sufficiently heavy and water-resistive to make satisfactory dikes; so the process is simply to turn a big dredge loose, piling up the bottom of the flat into a high ridge. At one stroke the waterway is deepened, and enclosed within a confining dike that protects the surrounding territory from reinundation. Our pictures show work of this sort in progress, and a scene where it has been finished, so that the greatly narrowed and deepened stream flows along with its surface well above the level of the surrounding country behind the dike.

Where the river walks on stilts, high above the fields

**The process of deepening the Sacramento River which results in banking it up in an artificial channel, well above the level of the surrounding country**

**General view of the British rigid dirigible R-80 after the successful completion of the trial flight**

# The Aerial Cruiser

## Some Details Concerning the Latest British Rigid Dirigible R-80

SOME twelve months after the notable trip of airship R-34 from England to America and back, a smaller edition of that ship, R-80, which embodies many improvements, had a successful trial flight. We present several views of this ship, and there follows a description of its construction and a comparison with the earlier and larger R-34.

At the time the ship was taken out for its first trial, the wind was blowing with a velocity of fifteen knots. The flight, which was carried out over the sea, lasted about two hours, and a landing was safely effected in a wind of about seventeen knots. Both in leaving the ground and in its return to the shed, R-80 was handled with facility and the trials were an unqualified success.

By way of comparison we give the accompanying table comparing R-80 and R-33.

### Construction

The main transverse frames are placed between the gasbag ends, with intermediate members. All the framework girders are of triangular cross section. Transverse wiring at the main frames transmits the lift of the gas to the keel girder and maintains the shape of the transverse section. A longitudinal stay connects the transverse wiring at each main frame. The main diagonal bracing wires are of three series—major, minor, and mesh wiring; the first two on the external surface of the ship. The mesh wiring on the inner surface of the girders transmits the gasbag lifting pressure to the framework. The triangular keel girder has its base formed by the lowest flat of the transverse frame polygon. This keel contains the cabin, bombs, petrol, water ballast, etc., and is sufficiently strong to transmit all loading, including the weight of the cars, into the main structure. There is a walking way the entire length of the keel girder, with branches to the wing cars, providing thoroughly sheltered communication.

The total gas space is divided into fifteen compartments, each containing one gasbag. The outer cover is formed with a number of separate panels laced to the girder, the joint space being covered with a sealing strip.

A novel feature is a walking way and hand line which run along the top of the hull. There is a g platform forward, and ventilation shafts are plac between each pair of gasbags.

### The Four Cars

There are four cars suspended from the hull, t two forward ones being placed one behi the other and joined flexibly together form one streamline shape. The forwa half is the control portion, and in it a found the navigating controls and instr ments and the wireless cabin; in the af portion there are two sets of engines. T two separate wing cars are suspended each side of the keel and each contains o set of engines. Particular attention h been given to the elimination of head r sistance and the cars, which are built duralumin, have a perfect streamli form. Opening windows of triplex gla are fitted where required, and in po tions of less importance there are wi dows of non-inflammable celluloid.

Below every car is attached a speci inflated buffer bag; these bags have su ficient buoyancy to enable the ship alight and float safely on the water, a they also make an effective cushion wh landing on the ground. The contro from the forward car are conducted up through t trunk, which leads from the car to the ship, and th they are taken forward or aft through the interi keel. There are large luminous indicators in the co trol car, which show the degrees of helm and elevation. All the gas valves are operated from t

**Two views aboard the R-80, showing how the British constructors are gradually refining their airships with the appearance of every new dirigible**

## What Are Great Britain's Mystery Towers?

IN a previous issue we printed an account of the two "mystery ships" then building for the British Admiralty. Their strange appearance and the air of mystery surrounding their construction and their use aroused great comment at the time.

Constructed on a sandy foreshore at Southwick, an obscure village between Storeham and Brighton on the Channel Coast, the two "mystery ships" have long been objects of interest. In shape they are not unlike a huge wedding cake, consisting of three tiers of hollow concrete blocks, surmounted by a tall wide tower, not unlike a gas-holder. The total height of each ship is almost 200 feet. Their method of construction is highly ingenious. The bottom story, consisting, as has been said, of hollow concrete blocks, rests on the foreshore; the tides play about it, and the long months during which it has lain on the beach have covered it with seaweed and barnacles. Powerful pumps are installed in the lower tier so that it may be pumped dry at will. Sluice gates are also fitted to enable it to be flooded and sunk. Until Sunday morning, September 12th, this lower tier was full of water, the weight of this serving to ballast the whole structure which towered above.

Early in the morning, at low tide, however, the sluice gates were opened and muddy water poured from the openings of the lower tier. As the tide rose the sluices were closed and the pumps were set to work. Within a short time they had lowered the water level in the hollow concrete by a further four feet.

Meanwhile the tower had been attached by hawsers to two lighters. As the tide rose—an exceptionally high spring tide for which the engineers had waited some weeks—the tower, now lightened of its ballast, rose too. Its ungainly bulk was trimmed until it floated upright—its upper deck some 200 feet above the crowd of spectators. The "launch" was accomplished slowly and without fuss. There was no excitement of greasy slipways and quick spectacular glissade.

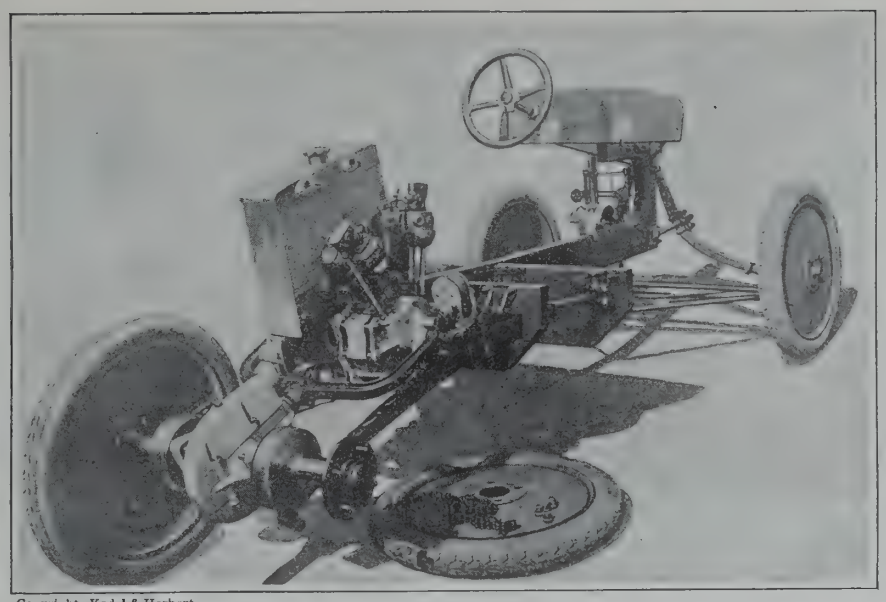
As soon as the tower had floated, a flotilla of Portsmouth Dockyard tugs stood by to tow it. The task was not easy. A specially dredged channel had been prepared; the draught of the tower is such that the clearance in some parts of the channel is measured in inches. Seven tugs were used in the towage. It was necessary to guide the huge bulk between wooden piers. Notwithstanding repeated warnings, these were lined with interested spectators, and a chance tilt against the piers would have seriously damaged both the tower and the pier, with probable loss of life.

The tricky passage was negotiated with only one unimportant mishap, and as soon as the tower was clear it was seized by additional tugs and slowly made its way by open sea (which was exceptionally calm) toward Spithead. It is thought that its destination is the Solent, but official quarters are reticent on this point.

Its companion tower is scarcely completed and conditions will not be suitable for its "launch" until the high tides of March next.

The whole of the arrangements for the building and launch of the tower have been under the charge of Capt Cliffe of the Royal Marine Engineers.

Speculation is still rife concerning the probable use of these mystery towers. One of the many theories advanced is that they will be used for raising the shipping sunk during the war by the German submarine campaign. By means of these towers, it is suggested, sunken vessels lying in water too deep or too rough for ordinary salvage could be raised. By "dragging," hawsers might be passed underneath the sunken vessel. The towers would be sunk, one on either side, and the hawsers made fast. The two towers (which may be submerged to a depth of 180 feet) would be simultaneously pumped empty of water, thus raising the vessel. The whole flotilla, with the vessel cradled between the two towers, coulb then be towed away to shallow water, where the vessel could be beached. By repeating this process it would be possible to salve vessels now lying far too deep for recovery. Such is the theory.

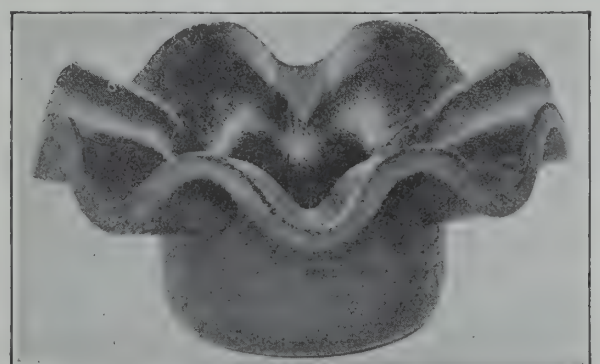


Copyright, Kadel & Herbert

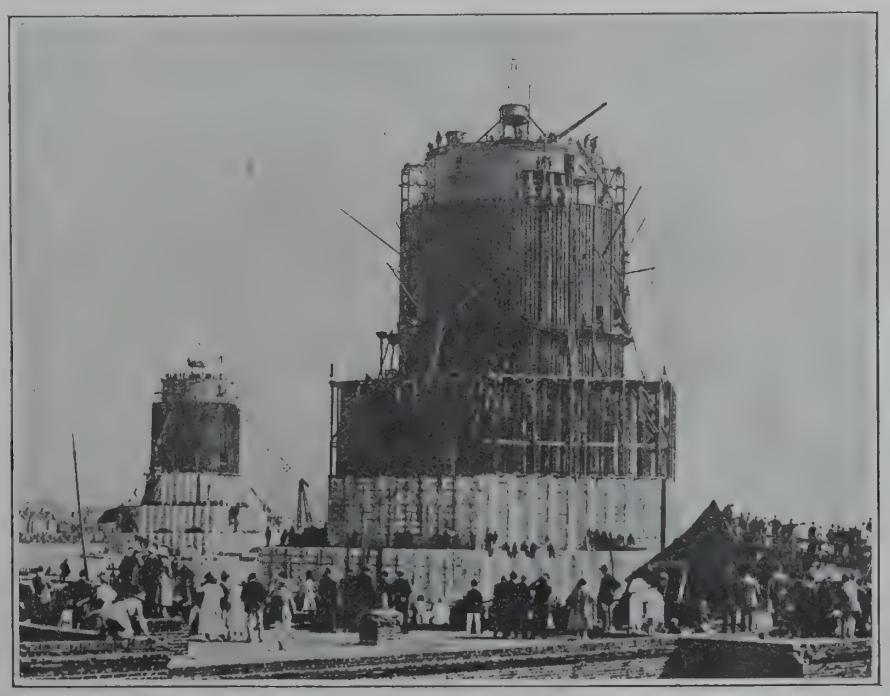
**This novel departure from standard practice represents a French effort at producing an inexpensive automobile**

Another suggestion is that had not the armistice intervened in November, 1918, some five or six of these towers would have been sunk in the Straits of Dover, made tight on the seabed with concrete grouted in, and pumped clear of water. The gigantic caissons so formed would have enabled work on the Channel Tunnel to be carried out with great rapidity. By sinking shafts in the interior of each tower, and driving headers in each direction from its foot, a dozen working faces would have been secured; whereas if the tunnel were to be driven from each end in the usual way, two only would be available.

Further suggestions are that the towers are destined to serve as protective underwater fortresses for the Naval Harbor at Portsmout—a contention which gains ground when it is remembered that the first tower has been towed to the Spithead.—By *F. Rawlinson.*



**This queer-shaped cup was recently moulded from a piece of leather over four hundred years old**



**What are they? The British authorities are satisfied to have them called "Mystery Towers," but will say nothing regarding their purpose**

## Reducing the Automobile to Its Essentials

FROM France comes the latest idea in automobile designs, namely, the frameless car. Indeed, here is a design which calls for an automobile that is practically all power and wheels, so to speak, with the usual parasitic elements reduced to the irreducible minimum.

A study of the accompanying view of one of the new cars tells the entire story. It will be noted that the usual frame construction is done away with, and in its stead we have little more than springs. The engine, which is a two-cylinder affair, is placed at the rear, so that this chassis is obviously intended for a two-passenger car. The radiator is placed sideways, as shown. The rear axle, it will be noted, is mounted on a pair of springs and held by a U-shaped member whose legs terminate in pivots on either side of the power plant, the latter being mounted on the center of the springs. All in all, this construction is exceedingly novel and ingenious, although it seems quite obvious that it can only be applied to the lightest kind of passenger cars. But for these it will surely economize fuel!

## There is Nothing Like Leather

THE leather cup which we illustrate is a striking proof of the durability of good leather, for it is at least four hundred years old. Proof of its age is found in the following facts. At some time prior to 1893 there was standing in the city of Hamburg, Germany, an old building which had to be removed to make way for improvements. Records and tradition established the fact that this building had been standing four hundred years. There is nothing very remarkable about that; but when the building had been torn down and the foundations for the new building were being dug, the workmen discovered some old tan vats, which were evidenty the remains of an old tannery that had been in operation on this site before this four-hundred-year-old building was put up. In one of the vats, which probably had been filled in with earth, they found a relic of the old tannery in the shape of a tanned hide. Part of this hide fell into the hands of a prominent merchant in Hamburg, who dealt in leather goods. He was sufficiently interested in the relic to have molded from a piece of the hide a leather cup, which he brought with him to America in 1893, at the time of the Chicago Exposition, and he left this cup with one of the largest of our leather manufacturers, who vouch for the integrity and standing of Mr. Gearckens, the donor of the cup. In consideration of its great age, it is a tribute to the quality of this ancient piece of leather that it could be molded into such a shape as this. We are informed that only a very high-class piece of leather would stand, without breaking, the pressure required to complete the right-angled bend at the bottom of the cup, as shown in the illustration. The forming of the fluting at the top of the cup was a strain upon the leather only a little less severe. Yet the leather has been bent and molded both in these convolutions and in the body of the cup itself without showing any cracks.

The *Bulletin* of the National Association of Leather Belting Manufacturers, in speaking of this interesting experiment, reminds us that the enduring life of good leather is due to the fact that it does not corrode or oxidize or disintegrate, and as this piece proves, will retain its life for centuries.

## Paper on a Specification Basis

RECENTLY a marked increase in the use of paper bags as containers for lime and cement was noted. Uncle Sam in his paper conservation campaign is investigating the various materials suitable for such purposes. He has devised an invaluable test machine which shows definitely the stress, strain value of the paper as well as the stretch which results under load. He now is perfecting a testing apparatus which will reproduce under laboratory conditions the strain on the bag when it is dropped. The idea of the government experts is to so correlate these tests that the actual service conditions to which bags are exposed may be reproduced in the testing laboratory.

# Items In Brief

*A Department Devoted to Current News in All Fields of Pure and Applied Science*

## *Electrical*

**X-Rays and the Shoe.**—A leading New York store has recently installed an ingenious X-ray outfit which permits its patrons to see just how their feet fit in any pair of shoes. In fact, at a glance the patrons can note the position of the bones of their feet in any given pair of shoes, and in that manner determine whether they are trying the proper last or not.

**Radio Control for Airplanes.**—There can be no doubt that if the war had lasted a few months longer we would have witnessed the leading armies employing great fleets of airplanes controlled by radio means. The United State Army had progressed pretty far along this line when the armistice was declared. The same can be said for Germany. Now we learn that the French have demonstrated that five or six small and inexpensive bombing planes, without pilot, can be successfully guided by a "shepherd" in a larger plane through the means of Hertzian waves.

**Glass Insulators for High Voltages.**—Tests with glass insulators have been in progress in Switzerland for several years, and numbers of these insulators have been used in France and the United States, for potentials up to 50,000 volts. The principal application for glass insulators is, however, up to 25,000 volts. Such failures as have occurred with glass insulators have been due principally to internal stresses which cause cracking when the insulator is subjected to heavy mechanical stress or sudden temperature change. The occurrence of such failures has been made less frequent by the use of improved material and better annealing. As for the puncture strength, it is higher than that of glazed hard porcelain. The glass used in Switzerland is clear and transparent, hence the absorption of solar heat is less than in the dark green glass hitherto employed.

**High-Power Arc Lamp.**—In the Garbarini rotating arc lamp the inventor aims at (1) a single light-source of small area and great brightness; (2) the integral utilization of the light from a source; and (3) the automatic maintenance of the point-source in its correct optical position. A horizontal, cored positive electrode is used forming a small central crater. The negative is of metal, cooled by circulating water or gasoline, and is non-luminous. It is annular in shape, and terminated by a ring-edge; the crater of the positive is situated at the center of the annulus. The arc formed between the annulus-edge and the unobstructed positive crater would tend to wander and become unstable. Accordingly a solenoid is mounted with the positive electrode as axis, and the magnetic field thus produced causes the arc to revolve at 500 to 3,000 r.p.m. At this speed the motion is not detected by the eye, which merely sees the central bright spot, the crater, surrounded by a slightly luminous haze. Such an arc has, in effect, uniform length and resistance and gives a constant light.

**New Tank for Transformers.**—A leading electric company is developing the use of a so-called conservator in connection with oil-filled transformers. The conservator consists of an auxiliary tank connected to the top of the main transformer tank by a suitable pipe and mounted above the level of the oil in the main transformer tank. The main tank and the connecting pipe are completely filled with oil, and the only oil that comes in contact with the air is that in the conservator. The size of the conservator is governed by the thermal expansion and contraction of the oil. The oil must not contract sufficiently to allow air to enter the main transformer tank, and when hot the oil must not overflow. In practice suitable oil gages, oil valves, chloride of lime chambers, and sump are provided in the conservator. The elimination of the air space in the main tank is of importance because this removes the chance of an explosive mixture of gas and air above the oil. Any gas that forms escapes into the auxiliary conservator tank, where there is no possibility of ignition.

## *Communication*

**Another Clandestine Wireless.**—The steamer "Eten," which was the German steamship "Rajah Kootis," may have played a more important rôle in the war than merely that of housing a number of interned German sailors in a Peruvian port. Indeed, upon examination at an American port it was discovered that a water cooler in a stateroom of this steamer contained a wireless set. The obvious conclusion is that the interned crew may have communicated with German sea raiders at various times.

**Safeguarding Radio for Emergencies.**—The United States authorities who watch out for the welfare of wireless on land and sea, report that operators have been using their auxiliary source of power (storage battery) for the operation of audions. The auxiliary source of power must not be used for any purpose other than that of operating the transmitter in the event of accident, when the usual ship's current supply fails. The battery must be kept fully charged and ready for immediate use. Any defects in the battery or any other part of the radio equipment should be reported to the master of the vessel immediately. Such neglect of duty on the part of operators may be considered sufficient cause for the suspension or revocation of their license.

**Light Telephony.**—It is quite obvious that the Germans, too, were working along the lines of telegraphy and telephony by means of light rays during the late war. In a recent issue of a German periodical there appears a description of an apparatus for effecting telephonic communication along a light beam. The receiving apparatus consists essentially of a conical tube with a plano-convex lens at the wider end and a special selenium cell at the lens focus. The cell is included in a special valve amplifying arrangement to which are connected telephones. The transmitter consists of an arc searchlight, and the microphone current is superposed on the arc current by inductive coupling. The radius of such an arrangement is limited to three or four miles for small apparatus.

**What Is It?**—From Denmark comes a brief—all too brief!—report of the work of one Rahbeck, the inventor of something new in the field of communication. In company with one Johnson, Rahbek has been working for six years on the new invention. They discovered a new force resembling electro-magnetism in 1917, and eight days later they evolved the type of loud-speaking telephone of which the violin string appears to be the essential part. Next the inventors constructed a pocket electroscope far more sensitive and more easily handled, so they claim, than all previous instruments. One use of this new force which they have put to work would be to increase the receiving capacity of wireless stations. The inventors are now working on a device which will permit of despatches being received twenty times more quickly than now. All of which is interesting, to be sure; but what is it all about?

**Recording Sounds with Light Rays.**—In connection with the several light ray methods of communication developed during the war, it is interesting to note the latest means of recording and reproducing sounds by means of light. A. O. Rankine, writing in the *Proceedings* of the Physical Society, tells us that the light from a photophone transmitter is concentrated on a narrow slit, an image of which is produced by means of an auxiliary lens on a strip of motion picture film, the slit image being transverse to the film. The variations in intensity of the light when sound waves are received by the instrument are recorded as variations in the density of the film after development. For reproduction of the sounds, light from an illuminated slit is focused on the film, behind which a selenium cell, connected to a telephone circuit, is placed. As the film moves, the intensity of the light reaching the cell varies in accordance with the density of the film, and the corresponding sound is heard in the telephone.

**British Cable Delays.**—Considerable delays are reported by the Postmaster General in the handling of telegrams from Great Britain to the Continent. Of late the average delay on messages sent to the Continent was about 4½ hours, with a maximum delay of 22¼ hours recorded. By way of comparison, the delays experienced during the same period in the case of other services were also noted. The average delay on messages to North America via the Imperial Cable is reported to have been 3¾ hours, with a maximum delay of 10 hours. The services to the Near and Far East were subject to an average delay of about 10½ hours, with a maximum delay of about 24 hours. Recently the British Post Office instituted an "urgent" telegraphic service to Paris, at three times the ordinary rate, in view of the practice of many business men in London sending cables for Paris via New York. It is reported that a specific test was made recently to determine the advantages of the new "urgent" service to Paris. The message which went by way of New York was delivered in Paris 20 minutes before the one sent by the "urgent" direct cable.

## *Industrial Progress*

**Baedeker Again.**—It is reported that the famous series of guide books known as Baedeker's, is again on sale in Germany. The first two volumes to come out are "Brandenburg" and "Saxony," thus indicating that Germany now is no longer to be regarded as one united state. Under the old régime there were four Baedekers of Germany. However, the thoroughness and accuracy of the text and maps alike remain at the pre-war standard of excellence.

**A Guide to Latin America.**—The need for a guide for commercial travelers to Latin America has just been met by a publication entitled "Commercial Traveler's Guide to Latin America," issued by the Bureau of Foreign and Domestic Commerce. For the convenience of the reader the book has been divided into two sections. The first part deals with general matters such as salesmen's equipment, transportation, suggestions for procedure upon arrival at destination, etc. Maps of Latin America accompany the guide.

**Better Rubber or Cheaper Rubber?**—A recent demonstration in India of a new process for the vulcanization of rubber took place at the Manchester College of Technology, it is announced in an issue of *Commerce*. Vulcanization of crude rubber mixed with a large proportion of waste material like leather shavings or sawdust was proved by this method to be chemically possible, as well as a saving in time and cost compared with existing methods. It is claimed that this process will produce a material which will stand the test of wear and weather.

**Our Standing in Shipping.**—According to Lloyd's Register of Shipping for 1920-21 just issued, the seagoing tonnage of the United States shipping has increased since 1914 by over 500 per cent. American tonnage now stands at 16,049,000 tons, which places the United States second only to the United Kingdom, which has 18,330,000 tons. Japan is now third, with 2,963,000 tons, followed by France with 2,963,000 tons. Including sailing ships, but excluding tonnage on the Great Lakes, the United States now owns 24 per cent of the world's tonnage as against 4.7 per cent six years ago.

**Consumption Estimates, 1919,** an annual publication of the Bureau of Foreign and Domestic Commerce, is now available. It presents condensed statistical tables showing production, imports, exports, and amounts available for consumption of various articles in the United States. Cotton, wheat, corn, sugar, wool, coal, pig iron, iron and steel rails, pulp wood, and tobacco are among the important trade items which receive individual attention. Copies are on sale at the Government Printing Office, Washington, D. C., and at the district and coöperative offices of the Bureau of Foreign and Domestic Commerce. The price is 5 cents.

**Milk from Peanuts.**—The common peanut is the source of a new substitute for milk which so closely resembles its prototype that it turns sour and curdles, produces butter milk when churned and may be made into cheese. The flavor, in which the nut characteristically persists, is declared to be practically its only point of variance with cow's milk. The new lacteal product originated in the laboratory of an American university where the peanut kernels are converted into four times their volume of milk, varying from 4 to 8 per cent in fat content and from 2.4 to 3.3 per cent in protein. The cost of production is said to be considerably less than the market price of dairy milk.

**Is Europe Going Back to Bartering?**—Trade with Germany on the part of Holland direct or on the part of other countries through Holland is becoming more and more difficult as a result of the exchange situation in Germany. The fluctuations of the value of the mark are great and violent, and the impracticability of forecasting the variations to even an approximate degree has made it almost impossible for German buyers

safely to import even the most necessary goods. Bartering has developed as one way out of the difficulty and is being practised to an increasing extent. For example, a deal was consummated recently for the sale of 1,000 tons of American flour to German importers for an equal value at current prices of coal-tar pitch.

## *Power and Fuels*

**Cotton Rope for Power Transmission.**—The superiority of cotton rope over manila is emphasized in a recent issue of the *Journal* of the Engineering Institute of Canada. Though the initial cost of the cotton rope is the greater, its superior resilience, grip, groove impact and prolonged life—five times that of manila—quite outweigh the disadvantage in first cost. Cotton ropes evaporate acquired moisture quicker than manila and are less susceptible to internal mildew.

**Steam Pipe Losses.**—The German Association of Steam Users has issued a pamphlet calling the special attention of its members to heat radiation losses from the surfaces of steam pipes and boilers. It is pointed out that such losses with steam at a pressure of 170 pounds per square inch and a temperature of 374 deg. F. amount to 924 B.t.u. per square foot per hour and represent substantial sums owing to the high cost of fuel. The expenditure incurred in providing good non-conducting material is not serious and is repaid in two months by reduction in the coal bill. The radiation from flanges is practically the same as from the corresponding area of pipe, and it is recommended that an efficient type of flange cover should always be adopted.

**Tidal Power.**—The power available from tides at a given station is analyzed and graphical methods are given for determining the level in the tidal basin to give a maximum value for the mean power, in a recent issue of the *Genie Civil.* Since turbines only run in one direction, they should be placed between two parallel channels, one for the inflow during the rising tide, and the other for the outflow during an ebb. Since the fall is variable turbines should be operated in series when the fall is considerable, and in parallel when the fall is small. At peculiar states of the tides there are dead periods when no power is developed. This becomes less troublesome if, instead of a single station, a series of stations is erected along the coast. The dead periods will not fall at the same instant at the different stations. It is recommended that the installation should combine tidal, up-stream water reservoirs and thermal plants. The latter of course are to be used as auxiliaries when the water power falls below the requirement.

**Wood Charcoal and Its Manufacture.**—The uses to which wood charcoal is put are numerous, chief among which may be mentioned its use as a source of cheap power for running gas suction engines, for smelting purposes, and for smithy work. It is also used as a smokeless fuel and in the manufacture of ammunition. On account of its porous nature and the very large internal surface it contains, charcoal has the power of absorbing large amounts of gases. Similarly, charcoal, especially bone charcoal, prepared by heating bones, will absorb coloring matters from solutions, so that it finds a considerable application as a decolorizing and deodorizing agent. It is utilized also for insulating purposes, as it is a bad conductor of heat and electricity, and is given to poultry in crushed form. The chief constituents of wood are cellulose and lignin, both rich in the element carbon, and when wood is burned in the presence of air, light, heat and gases are produced, while ashes containing the mineral constituents of the wood form the residue. When heated to high temperatures without free admission of air most of its organic substances (cellulose, lignin, etc.) are decomposed and given off as gases, a residue of impure carbon remaining. This impure carbon residuum is called charcoal, and it consists almost entirely of the the element carbon mixed with a certain amount of still undecomposed carbon compounds and the inorganic constituents of the wood chiefly in the form of potassium carbonate.

## *Engineering*

**Making Good the Roubaix Canal.**—Certain sections of the Roubaix canal were demolished by the Germans in their retreat in 1918, and it is the repair of these sections that *La Technique Moderne* recently described. The work carried out included the excavation of the canal bed, and the locks, work of checking the still apparently sound portions, remaking of damaged and destroyed portions, provision and erection of lock-gates, substitution of new parts for the temporary parts supplied and erected provisionally by the Allied Armies, construction of bridges to replace those destroyed, and other subsidiary works. The work was carried out very rapidly on the most modern lines, concrete being used largely in place of rubble and other materials. In the Roubaix section of the canal the whole of the ruins have been excavated, the canal bed dredged over a distance of 20 km.; 13 locks have been replaced, and 49 road bridges, viaducts, and foot-bridges re-erected over the canal.

**T.N.T. as a Blasting Explosive.**—The U. S. A. being left with millions of pounds of surplus T.N.T. on the conclusion of the war, the problem has arisen how best to utilize it in industry. Experiments made by the Bureau of Public Roads demonstrate that T.N.T. can be used with reasonable safety, but is not so economical as dynamite. It can be made more effective and also cheaper by admixture with sodium nitrate, ammonium nitrate, or other cheap oxidizing agent which will consume the excess combustible matter in T.N.T. It may also be desirable to add waterproofing material. Moisture and temperature do not materially affect the work of T.N.T., nor does it appear to affect the health of the user in open-air work. The amount of T.N.T. required for such work is about 75 per cent of the necessary charge of 20 per cent ammonia dynamite, continues the *Road-maker, Excavator and Grader.* On account of the smaller quantities used, definite sizes of cartridges should be made, since there may be considerable danger from overloads if the material is not properly cartridged.

**Upward Pressure of Dams.**—Experiments are described, which aimed at adding to the meager fund of information available regarding the upward pressures existing under masonry dams and other similar structures on porous foundation, in a recent issue of *Engineering News-Record.* The determinations were made at the Island Park Dam, Dayton, Ohio, and the apparatus employed was very simple. An unexpected discovery was that methane gas was accumulating in considerable quantities beneath the dam, and it was found that this gas had the effect of increasing the upward pressure, or the tendency of the dam to float. From the experiments it seems evident that although sheet-piling and cut-off walls are of value in reducing upward pressures, their effect is not necessarily in accordance with the line of creep theory. The results obtained are probably not representative of conditions existing immediately after the closure of the dam, and it is therefore concluded that the greatest danger exists when the head against such a structure is first accumulated. The upward pressure may soon be reduced to an unimportant factor, the length of time required to bring about the change being dependent upon the rapidity with which silt is deposited over the bottom. The formation of gas under the dam is a potential source of danger, if the shape of the structure is such as to confine the gas.

## *Pure Science*

**Radiotelegraphic Research at Woolwich.** — According to *Nature* many important investigations in radiotelegraphy are under way at the experimental establishment of the British Army, at Woolwich. Speeds of transmission of from 450 to 1,000 words per minute are attained by an adaptation of the Wheatstone automatic transmitter. Special attention has been given to the linking up of line with wireless systems. High-speed messages, coming in over the wire in the ordinary way, are automatically transferred to the radiotelegraphic apparatus without loss of time in retransmission. The British Army is much interested in direction-finding apparatus, and very compact sets for this purpose, with a range up to 250 miles, are being standardized at Woolwich.

**A New Journal of Physical Abstracts.**—For more than three-quarters of a century the chief repository of physical abstracts for the world at large has been the *Fortschritte der Physik,* which, in recent times, has comprised three volumes a year. In order to ensure a more rapid dissemination of abstracts of current literature in physics, the Deutsche Physikalische Gesellschaft has discontinued the publication of the *Fortschritte* and a new semi-monthly journal, similar in contents, called *Physikalische Berichte,* has been started by the above-named society in conjunction with the Deutsche Gesellschaft für technische Physik. This publication will also supersede the *Halbomonatliches Literaturverzeichnis der Fortschritte der Physik* and the *Beiblätter zu den Annalen der Physik.* Dr. Karl Scheel, who edited the *Fortschritte,* is editor of the new journal, which is published by Vieweg & Sohn, Braunschweig.

**Foodstuffs Fumigated with Cyanide Gas.** — The Public Health Service has investigated the possibility of the adsorption or absorption and retention of cyanide gas by foodstuffs during the process of fumigating vessels, warehouses, etc., with resulting danger to the consumer. The foods selected for the test were fresh bread, which, on account of its spongy structure, offers excellent conditions for the adsorption of the gas, and milk, because it is the most available liquid food. The bread and milk were exposed to cyanide gas under a bell jar for periods varying from 2 to 22 hours, and subsequently fed to white mice. If given to the mice immediately after exposure to strong fumes of cyanide, poisoning resulted, probably from the fumes temporarily retained by the food. When the food was exposed to the air for an hour or two, it was harmless to the mice. The conclusion is that the possibility of poisoning occurring from food materials exposed to cyanide gas under ordinary conditions is extremely remote.

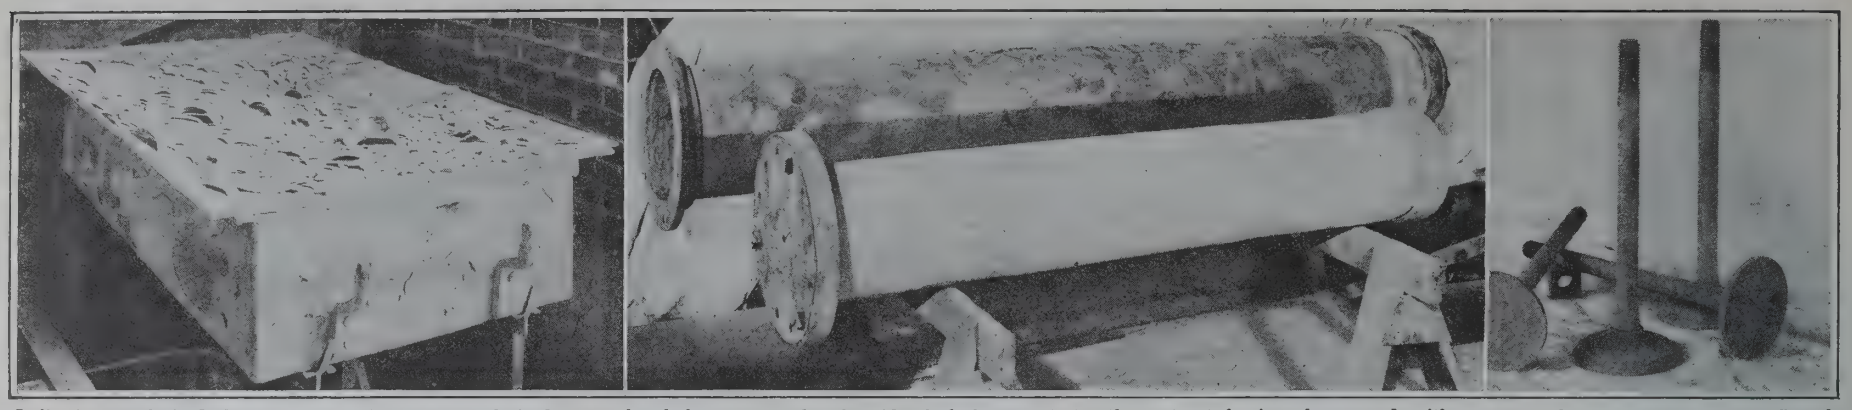
**Motion Pictures of Weather Maps.**—The U. S. Weather Bureau has been investigating the plan of making motion pictures of weather maps, as already carried out, in a tentative way, in Europe. Prof. J. Warren Smith, who has this matter in hand, reports that scenarios have been outlined to show: (1) The movement of a West Indian hurricane from the Atlantic into and across the Gulf of Mexico and thence across the eastern United States to the Gulf of St. Lawrence; (2) the movement of cold waves; (3) heavy rainfall and floods; (4) heavy snowstorms; (5) local thunderstorms and tornadoes; and (6) comparisons of the climate of different areas. The movements of storms and weather conditions will be shown by weather maps drawn for every 15 minutes, and each map will be photographed from 6 to 48 times. The maps will be accompanied by motion pictures showing the actual weather and its effects, including storm damage, waves on the coast, snow scenes, orchard heating to protect against frost, etc.

## *Automotive Progress*

**Change Oil in Crankcase to Prevent Wear.**—A recent test showed that to prevent excessive engine wearing crankcase oil should be changed at least every 1,500 miles, preferably every 1,000 miles. A new engine that was run 6,000 miles with oil changed at proper intervals, upon being disassembled showed no signs of wear. The same engine, reassembled and run 6,000 miles with old oil plus new oil as needed, upon inspection showed a wear of 0.015 inches. Motor truck and passenger car manufacturers recommend, for better performance and longer life, that crankcases be drained every thousand miles, the engine flushed with kerosene and new oil added.

**Growth of Motor Express Lines.**—Motorized highway transportation is growing with astonishing rapidity. New York State alone has over four hundred motor express lines in operation. It is estimated that, for the whole country, there are not less than 5,000 such lines in operation. These lines are of greatly varying size and widely scattered. The American Motor Freight Company, with headquarters at Sioux Falls, South Dakota, is incorporated at $500,000. A map of its route includes 80 towns in Minnesota, Iowa and South Dakota. The New England Transportation Co., which operates out of Boston, is reported as having 150 motor trucks in service which operate over 12 routes totaling over 1,000 miles in length. The Patriot Motor Express Company, of Wichita and Kansas City, Kansas, is capitalized at $1,000,000. It is operating throughout Kansas, Nebraska and Missouri and will use 150 motor trucks.

**Chicago Limits Truck Weight.** — Amendments to the traffic ordinance in Chicago have been drafted to be submitted to the city council with a view to preventing rapid destruction of the street pavements by excessively heavy traffic. The proposed changes were discussed at a recent meeting in the office of the city engineer, Mr. Coombs, who is chairman of the special traffic commission charged with drafting the amendments. It is proposed to change the gross weight of vehicle and load from 40,000 pounds, as at present allowed, to 30,000 pounds, with a maximum weight of 1,000 pounds per inch width of tire, but it was agreed at the meeting that the combination of a motor truck and semi-trailer with load should be allowed a weight of 32,000 pounds, with a limit of 24,000 pounds on any one axle. During the meeting the city engineer said he was very much in favor of the use of trailers and felt it was preferable to have loads spread over the six or eight wheels of motor truck and trailer or semi-trailer rather than to have the weight concentrated on the four wheels of the machine carrying the load alone.



*Left:* An uncalorized sheet of iron and a smaller calorized rectangle of the same stock, after identical furnace tests—the untreated piece is covered with severe scale, the other is not affected. *Center:* Calorized (front) and uncalorized (rear) retorts after equal service. *Right:* Diesel-engine valves, a fair sample of the sort of thing that may profitably be calorized

# Preventing Rust at High Temperatures

## Aluminum-Coated Metals That Will Go to the Melting Point Without Formation of Scale

By Robert June

THE problem of devising means of protecting metals from oxidation at high temperatures has occupied the attention of metallurgical engineers for many years. The remarkable industrial developments of the past few years, particularly with respect to heat treating processes, have made this problem of pressing importance; and it has consequently received greatly increased consideration.

To say at the outset that this problem has largely been solved by the development of what is known as a calorizing process is to sum up the experiences and opinions of many metallurgists and industrial engineers who have encountered serious and at times seemingly unsurmountable difficulties in the rapid oxidation of metal parts at high temperatures.

In the calorizing process, the metal chosen is aluminum, and the protective action is due to the oxide formed by the action of heat on the protecting alloy rather than to any electrolytic relations between the aluminum and the base. The product is distinguished from that of other processes such as sherardizing, hot galvanizing, etc., in that these are intended primarily to give protection against oxidation at ordinary temperatures, or corrosion, as it is frequently called, while the calorizing process is intended primarily to protect against oxidation at high temperatures.

Practically all metals suitable for structural work, with the exception of those in the platinum group, began to oxidize at quite low temperatures; on the Centigrade scale, steel at about 370 degrees, copper at 360, nickel at 660, nickel-steel (58 per cent nickel) at 530, chrome-nickel (10 per cent chromium) at 650, German silver at 530, and aluminum-bronze (9.2 per cent aluminum) at 600. As a matter of fact most of these metals or alloys may be run at a higher temperature than that indicated before serious disintegration sets in, but none of them has a very short life at or above a full red heat.

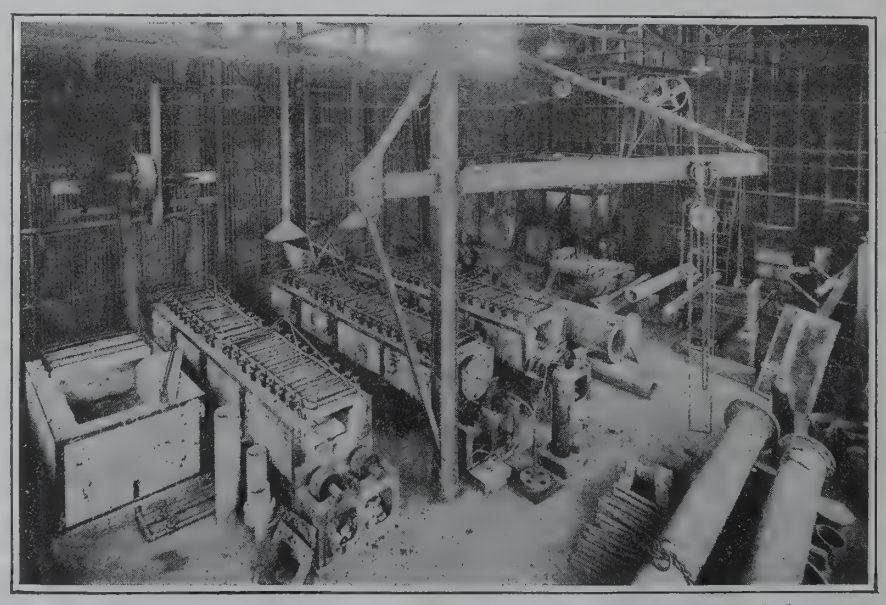
It is well known that an aluminum wire heated by an electric current above its melting point will still maintain its shape due to the tough and resistant oxide of aluminum formed on its surface. It is this oxide which is the basis of the oxidation-resisting properties of calorized metal. It is necessary, however, to have sufficient aluminum present to form a continuous coating of $Al_2O_3$ over the whole surface. Experiment has shown that this requires, in the case of iron alloys, at least 14 per cent of aluminum.

The calorizing process was developed about 1911 in the electrical research laboratory at Schenectady, in the course of a series of experiments instituted to find a method of protecting electric heating elements. The process was later turned over to an independent corporation, as its industrial and commercial importance warranted its handling by a separate organization specializing in oxidation problems.

In treating metals by the calorizing process, they are first thoroughly cleaned by sand-blasting, then placed in a stationary or rotary retort in a reducing atmosphere, with a mixture composed of finely divided aluminum and aluminum oxide. This treatment, conducted at a temperature of 600 to 1,100 degrees Centigrade, depending upon the depth of alloy desired, so thoroughly infuses aluminum into the exposed portion of the metal being treated as to form a homogeneous aluminum alloy for a certain depth. This depth ranges from a few thousandths of an inch to the permeation of the entire mass, varying with the duration of the treatment.

The essential point in difference between the effects of calorizing and most of the processes hitherto used commercially, such as galvanizing, plating or coating, is that the protective metal is not imposed as coating or skin upon the metal to be treated, but rather enters into intimate association with it, forming a "solid solution" alloy. For this reason, should the outer surface become slightly injured, the protective surface renews itself. Calorizing is not intended to protect against rusting or corrosion, as is sherardizing for example, but is primarily a protection against burning or scaling. Calorized copper, brass and nickel, however, are also excellent non-corrosive elements and are strongly resistant to the acid. The dimensions and weight of the metal treated are very slightly increased by calorizing. The increase in dimensions is usually not over a few thousandths of an inch.

An example of its commercial application is in the manufacture of soot blowers, which as applied to boilers must be exposed continuously to furnace gases at high temperatures, and are not cooled by water or steam as are boiler tubes. Ordinary iron or steel will not give successful service. Under these conditions, one of the early means employed in protecting this equipment against burning out consisted of two extra heavy steel pipes, placed one within the other, the space between being filled with insulating material of special composition. This type of installation was fairly successful, but involved an excessive first cost; therefore, manufacturers of soot blowers were constantly on the lookout for material from which these units could be economically made, and which would give even more satisfactory results. Very soon after the calorizing process was announced, a comprehensive investigation of it was made in this application.



**Retorts and furnaces in which the calorizing process is carried on**

In addition to mechanical tests, trial installations were made in all the different types of water-tube boilers. In making tests, calorized soot-blower units were placed in the hottest passes where the temperatures ranged from 1,800 to 2,500 degrees Fahrenheit. The need of blowers at these locations had long been recognized, but their application had been considered impracticable. Performance of the calorized units was watched with keen interest for months. In the end they proved that they fully met the hardest service conditions. There were no signs of scaling or disintegration from the long exposure to high temperatures. Thousands of successful installations have been made, and are now giving satisfaction in all types of water tube boilers. In addition to the matter of oxidation, many gases contain sulfur dioxide and carbon monoxide, which have an extremely deleterious effect on ordinary metal, while tests have shown that calorized metal is not affected by them in the percentages in which they occur in furnace gases.

The resistance of calorized iron to oxidation is a time-temperature function. It will resist oxidation up to its melting point for a short time, but to obtain a reasonable life, temperatures exceeding 900 to 1,000 degrees Centigrade should not be used unless the calorinzing treatment was unusually heavy. The reason for this is evident when we consider that the diffusion of the aluminum into the iron is extremely rapid at high temperatures. It is about five times as fast at 1,300 as at 110 degrees Centigrade, which would cut the life to one-fifth when used at the higher temperature. By using thin sections and a heavy coating, however, steel may be calorized to stand the higher temperature for months.

Although tests show that the mechanical properties of the steel are not injured by calorizing, it must be pointed out that the rich aluminum alloy which forms the protective coatings is very hard; any bending or mechanical working should be done as far as possible before calorizing. If it must be done afterwards, the piece should be first heated to redness. Calorized metal cannot be hammered or bent cold, but at a bright red heat can be bent without affecting its resistance to oxidation. However, calorized metal is capable of withstanding all ordinary handling without destruction of the alloy or calorized portion.

Calorizing has been put to a great variety of uses including its application to retorts, carbonizing and annealing boxes, pyrometer tubes, furnace castings, tubes for preheating air, flue lining, pipe for conveying molten glass, torch nozzles, blast furnace tuyeres, oil crackers, soot-blower units, lead pots, valve and piston heads for Diesel engines, preheating coils for oil burners, hot bulbs for oil engines, etc. Calorization has been successfully applied to carbonizing and annealing boxes and a variety of heat treating equipment of this nature, the treatment prolonging the life from three to thirty times.

It is entirely feasible to make up calorized coils of pipe in a wide variety of

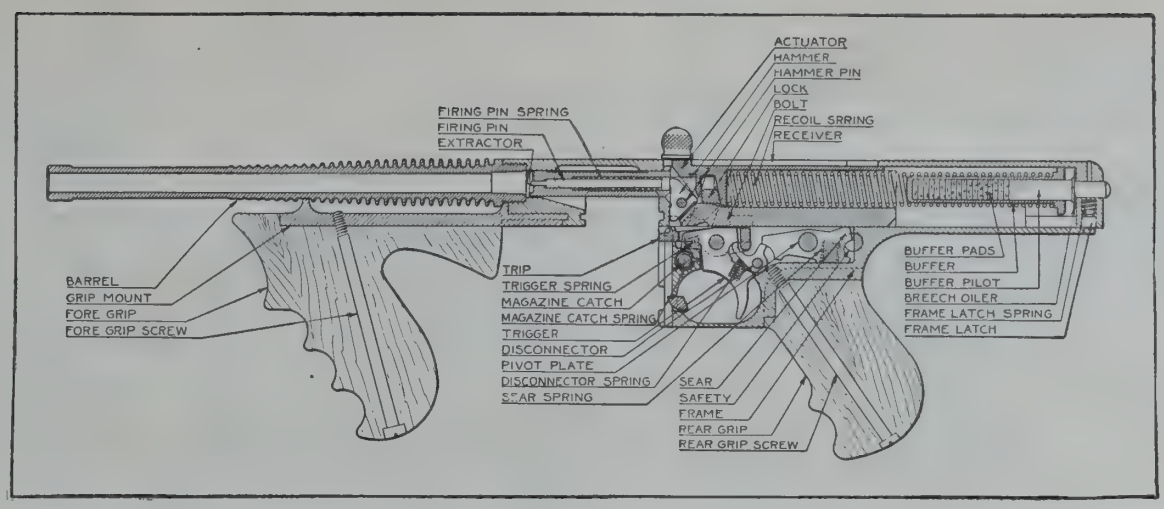
## A Pocket Machine Gun

By Capt. E. C. Crossman, U. S. A.

THE marksmanship of the average policeman with the average policeman's revolver is something to make honest men turn pale, and the women and children duck for the subway. Here and there are exceptions, but as a general rule policemen seem far inferior to yeggs when it comes to hitting things they intend hitting with the pocket gun. I do not know whether the yegg spends some portion of his ill-gotten gains in target practice or whether his ability to hit, where the officer misses, is due merely to the cussedness of inanimate nature. The fact remains. Wherefore the announcement in the public prints of the adoption by the New York police of the wicked little Submachine Gun is of course interesting to those persons who wish to see the customary New York brand of gunplay made a little less one-sided.



**Cross-section of the pocket machine gun, showing its components and the general assembly**

Without doubt the early future will see a happy coincidence of a policeman skilled in the pointing of the new weapon, and an automobile full of yeggs willing to engage in the customary running gun flight. The result will be the worst-shot-up assortment of crooks that has come to the attention of the coroner.

The new gun as adopted by New York consists of a 7-lb. weapon, 22 inches over all, and capable of being carried in concealment. It is sort of a compromise between a pistol and a rifle, with the speed of fire of the highest speed aircraft machine guns. It is turned out by a new and strong organization headed by the former Assistant Chief of Ordnance of the Army, the officer who gave to the Army the M 1917 rifle during the war.

As designed for American use it is chambered for the caliber .45 automatic pistol cartridge, with its powerful and knock-down blow inflicted by the 230-grain bullet. The barrel is less than a foot long. A grip for the left hand lies below the center of the barrel, while another for the right hand lies near the rear end of the gun, below the breech casing. The magazine is between the two grips.

So arranged, the gun is intended to be fired from the waist line, the fire being directed by the sense of feel, as one throws a stone, and as used in the "marching fire" of attacking infantry during the war. The arm is truly automatic, not the semi-automatic self-loading type so often miscalled automatic. Such arms require a pull of the trigger for each shot, the mechanism merely ejecting and reloading the gun. The Submachine Gun is a true machine gun in that it fires as long as the trigger is held back and the cartridge supply kept up. This particular arm, however, has a theoretical speed of fire of 1,500 shots per minute, higher than any other weapon on earth, and three times as high as the average of machine guns used for land use among various armies.

If the trigger is held back, the result is a verberating roar of shots coming so fast that the ear cannot distinguish them apart. This of course empties a twenty shot magazine in less than a second; but the fire is easily controlled by the trigger pressure, and I found no trouble in firing single shots merely by a quick pressure of the trigger and instant release. Any number of shots between the single shot, and the entire capacity of the magazine is thus at the disposal of the firer.

Were the gun designed for a military cartridge and of this weight and proportions, it would of course be absolutely unmanageable in automatic fire. Those who have used the 16-lb. Light Browning automatic rifle can testify to the difficulty of keeping the gun from whirling the firer around and twisting the gun toward the sky. The recoil of the .45 pistol cartridge, however, is very light, and the writer, accustomed to handling the Light Browning rifle, found it easier to control the fire of the Submachine Gun than the Browning automatic rifle. The gun is fed by magazines of varying capacity from the flat, box-type, 20-shot affair, to the drum-shaped carrying 50 or 100. A feature of the arm is its absolute simplicity and fewness of parts. When resolved into its components for cleaning one can discover only fourteen or fifteen parts, and the gun is taken down without a tool and in a few seconds.

The arm is novel in that its designers arranged it to be oiled—as they say like any other gas engine, which is of course the correct classification of the automatic rifle or machine gun. Felt pads lying within the receiver walls and so out of the way of dust and grip, are impregnated with oil, which the bolt picks up in its reciprocating motion. The advisability of oil in a machine gun for military use is open to question, but the certainty of function of this little gun, and its terrific rate of fire evidently owe much to the oiling of the parts and lead to thought as to whether or not this is not desirable with any other weapon of this high speed, heating and hitherto rather unreliable type. Nothing more elaborate is required in this oiling than a squirt of an oil can into the pads every 500 shots or so, nor will the gun cease to function if it is not oiled.

The writer, as fire control officer of the Small Arms Ballistic Station at Miami and Daytona, Fla., conducted by the Ordnance Department of the Army, was

# What Science Did for Cheese

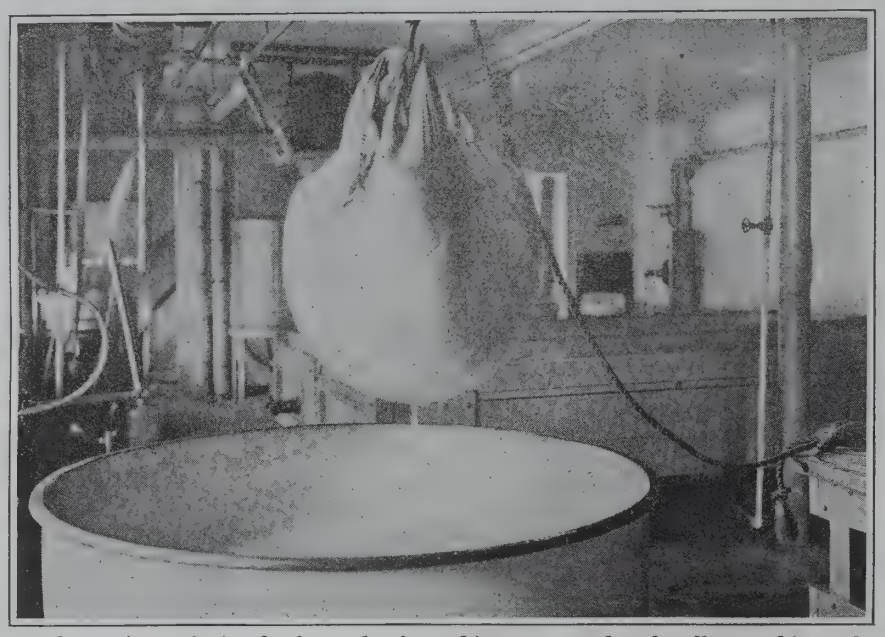
## How Precision Was Substituted for Guesswork in the Making of Swiss and Other Varieties

By George H. Dacy

ONE of the most recent scientific discoveries of the National Department of Agriculture has eliminated the gamble from Swiss cheese manufacture and has made it possible for American cheesemakers to produce better cheese than the best which ever emanated from Emmental, Switzerland, the Alpine native heath of dairy delicacies of this description. The art of Swiss cheese making—for it was an art which was handed down from generation to generation of hardy Switzers—was never dependable; the maker—no matter how experienced and skilful—was always liable to run into snags in the way of unfavorable climatic conditions or other environments which proved prohibitive to the rapid multiplication and activities of the organisms which framed the holes in the cheese and imparted to it the sweet, nutty flavor characteristic of the best imported Swiss cheeses.

We American consumers as a class were not familiar with these inside facts of the manufacturing complexities, because none but the best Swiss cheese was ever exported from Switzerland. However the prices which we had to pay for these imported food-products were accurate reflections of the trouble and losses involved overseas in their manufacture. Under the rule-of-thumb methods which previously have been typical of Swiss cheese production, ordinarily only from 40 to 50 per cent of each batch of cheese that was made was high grade while the balance was of inferior quality, selling for low prices. More than five centuries of experience in cheese manufacture were fruitless so far as the standardization was concerned and assurance that a certain proportion of high quality material would obtain from the operations of the maker supplied with plenty of milk and allied conditions necessary for Swiss cheese production.

In 1845 twenty-seven families of Swiss migrated to Green County, Wisconsin, with the intention of establishing the Swiss cheese industry in the United States. Natural conditions were as favorable as they were in Switzerland for the development of dairying in the Badger State. However, the same impediment which had proved insurmountable abroad obstructed the rapid rise and expansion of the business in America—the inability of the makers to standardize the processes of manufacture and to guarantee a definite and dependable output. Appreciating that the Swiss cheese industry presented profitable opportunities and afforded a remunerative market for milk if permanently established in this country, specialists of the National Department of Agriculture some years ago essayed the task of solving the perplexing conundrum.



**Potcheese is made in the home by just this process—but hardly on this scale. The housewife would be puzzled by a draining bag that must be handled with a half-inch rope**

*NUMEROUS jests have been cracked about the holes in Swiss cheese, and the man whose job it is supposed to be to make them. But when the experts of the Department of Agriculture tried to get at the bottom of this business, they discovered that even the cheese-makers of Switzerland knew nothing about it, their methods merely working because they worked. It required, in fact, twelve years of investigation and experiment before the particular "bug" that is responsible for the holes and the distinctive flavor of the Swiss product was isolated and put on his good behavior. This and several related stories Mr. Dahl tells in this account of what the Government scientists have done for the American cheese industry.*—THE EDITOR.

These experts spent much time with the Swiss cheesemakers in America, striving to gain insight into the riddle from carefully studying the various operations. The cheesemakers themselves knew absolutely nothing about the scientific principles involved. They did such and such a thing merely because their fathers and grandfathers had done likewise. Completely baffled in their attempts to wheedle illuminative information from the domestic producers and unable to reduce the knotty problem to a brass-tack basis by their laboratory experiments, the experts finally went to Emmental, where they investigated intensively and left no stone unturned in their untiring efforts to crack the tough-coated nut. However no one in Switzerland knew the "why" and "where" of the various operations which they performed in making Swiss cheese so that ultimately Uncle Sam's scientists had to return to this country without a solution for the question, "What causes the holes in Swiss cheese?"

Bewildered but yet undefeated, the agricultural experts resumed laboratory investigations with the full appreciation that if the problem were ever to be solved it would have to be cleared up through scientific experimentation. They extracted all the bacteria—of which there were 1,000 and more—from a fine sample of imported Swiss cheese. By an elimination process, they subsequently tested out each individual bug, in turn, despite that it took twelve years to complete this highly technical exploration. The results were not promising until finally the experts decided that a change of media for the development of the bacteria was necessary. The solution of the conundrum hinged on the use of the new culture medium. Shortly the scientists isolated the particular organism which formed the holes in Swiss cheese and thereafter they revamped the entire method of production to a strictly chemical and technical basis, with the consequence that, at present, it is possible to guarantee that at least 90 per cent of the cheese crop which is made according to the new methods will be of excellent quality, adapted to suit the requirements of the most critical trade.

Heretofore, we have consumed about 20,000,000 pounds of imported Swiss cheese annually while our domestic output according to the old methods of manufacture had almost reached a similar production

(*Continued on page 414*)

The novel design of this stirring tool is an essential feature

Swiss cheese sojourning in the curing room

**Stages in the manufacture of Swiss cheese, according to the scientific methods worked out by the Department of Agriculture**

Weighing less than 200 pounds, this two-passenger car runs 75 miles on a gallon of fuel

## Speaking of Automobiles—Here Is a New One

A NEW little car, being developed by a Chicago concern, is intended to attract resort trade and the tourist. It will fit in a trunk, if the trunk is large enough; of completely knock-down construction, on a buckboard chassis with motor-wheel behind, with room for two full grown people and a weight of but 200 pounds, it will catch the trade of those who need some rapid means of transportation to get over the country. On a gallon of gasoline it will run from 75 to 80 miles. By loosening screws and bolts in a very few minutes it can be turned into a roadster or small touring car. Complete control is from the steering wheel.

## Eliminating the Troublesome Motion-Picture Bug

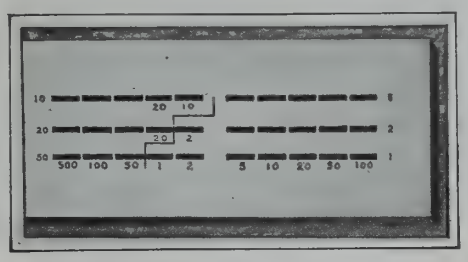
THERE is the motion-picture "bug" who is forever trying to worm his or her way into film productions. There are tens of thousands of such "bugs," and they are familiar to all of us. But this story has to do with another species of bug whose number runs into the millions, yet whose activities are more or less unknown to the general public. This species of motion-picture bug is the moth which flies around the powerful lamps of the indoor studio, and which has heretofore been responsible for many thousands of feet of wasted film.

It has remained for F. S. Mills and Clyde Ewing, motion picture men of Hollywood, Cal., to invent a machine that does away with the troublesome motion-picture bug—the winged variety, of course. This machine, which is shown in the two accompanying illustrations, consists of a wide box, a carbon arc, two incandescent lamps of 2,000 candle-power total, a funnel, a powerful suction fan driven by an electric motor, and a large box-shaped net. The operation of this device is simple. The bugs are attracted by the lights and on flying toward them they must pass over the arc. The intense heat burns them while the suction fan draws their remains into the box-shaped net. In a recent test the machine netted nearly ten pounds of bugs in less than that many minutes. By number the total haul was estimated in excess of 12,000 bugs. The lights of the apparatus are turned on during the rehearsals, so that all the bugs in the immediate vicinity are harvested, so to speak, leaving the air free until the banks of arc lamps or mercury-vapor tubes are flashed on for the actual filming work.

Two views of the "bug-catcher" now being employed to free motion-picture studios of troublesome moths

## Handling Paper Money by Push Buttons

WORKING on the problem of handling paper money by machinery, Frederick C. Weber of New York City has evolved a machine which appears to be as practical as it is ingenious. This machine consists of a cabinet divided into suitable compartments for holding the paper money, and topped with a



Typical panel used with paper-handling machine, showing the arrangement of slots

panel containing slots and push buttons. The paper money is wrapped in paper bands which feed out through the slots. The paper bands are divided off into envelopes which, due to the perforations separating one from the other, can be immediately torn off, thus forming a separate envelope with the money enclosed.

The machine contains a large number of envelope bands, as they might be called, containing various denominations and amounts of paper money. As will be noted by the keyboard depicted in one of the accompanying illustrations, the money is wrapped up so that any amount can be obtained by pushing the proper button. Thus by pushing a certain button the envelope comes through the slot in the lower-right hand corner, containing 100 one-dollar bills. The next slot to the left contains packages of 50 one-dollar bills. The next, 20 one-dollar bills, and so on. The arrangement of this panel is optional, of course, and can be designed so as best to suit any particular requirements.

The paper money, wrapped up in individual envelopes which form part of a long paper belt, is handled in advance by the average office help. Away from the rush and turmoil of the cashier's desk, this work can be carefully done and duly checked to avoid errors. The paper belts are placed in the machine at the beginning of the day's business. As for the handling of these belts, this function is taken care of by an electric motor driving an arrangement of rollers, which feed out one envelope at a time, which can be torn off; indeed, the action is similar to that of the automatic ticket machines now used in many motion-picture theaters.

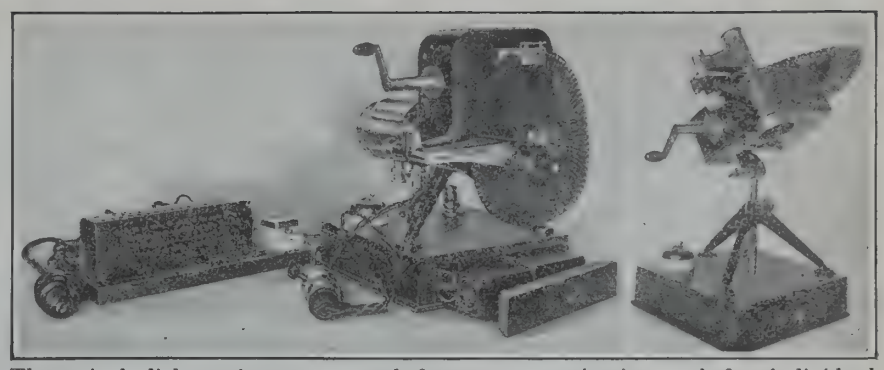
The new paper-handling machine can be used in conjunction with the usual coin-handling machine. It does away with the long waiting line of customers. It relieves the nerve strain of accurate counting of money, and enables the teller to wait on two or three times as many customers as at present. It furnishes an automatic record of all money paid out and the cash balance of every denomination on hand. It is claimed to be proof against daylight holdups; it is sanitary.

This machine handles paper money with as much facility as the usual coin-handling equipment

## Home Motion Pictures in Disk Form

IT has remained for Charles Urban, a pioneer worker in the field of motion pictures and the inventor of one of the most successful processes of natural-color motion pictures, to introduce a simple motion-picture apparatus for home and kindred use. By replacing the usual film with flexible disks, this inventor has simplified and reduced the cost of motion pictures to a point where they are available in almost every home.

The basis of the present system is a transparent disk on which the images are arranged in a continuous spiral. It has been found impractical to utilize a disk negative for photographing the subjects, hence the process makes use of standard positive motion-picture film which is projected in greatly reduced form on to the master disk. Once this master disk, which is a negative, is obtained, it is possible to print any number of positive disks for use in the projector. This reduction process requires most precise handling, and it was only after many years of constant development that the present successful results were obtained.



The spiral disk projector as used for screen projection and for individual viewing of pictures

The projector, which is shown in the first of the accompanying illustrations, embodies the usual elements. It has an incandescent lamp, condenser, shutter, lens and an intermittent gear. The operation starts with the first image on the outer turn and follows the spiral to the innermost image. Obviously, the pictures do not have to be rewound, as with standard film.

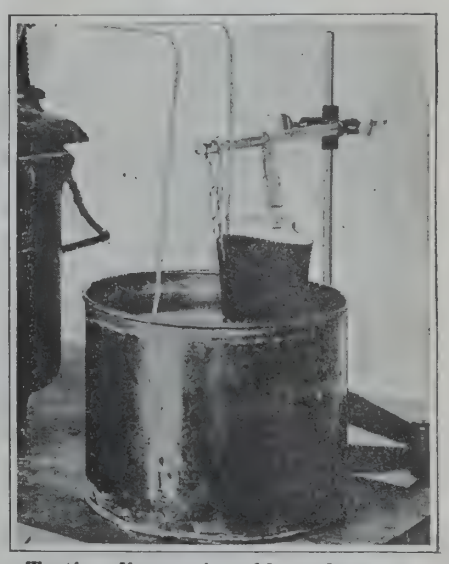
The actual size of the images is 7/32 by 5/32 inch. The 10½-inch disk contains 1,200 pictures, or the equivalent of 75 feet of film, exclusive of titles. Only two frames are devoted to titles, since the machine can readily be stopped when a title is reached, and then started up again, thus saving a great number of frames. In this manner the record may be said to equal the usual 100-foot run of film with titles. This matter of being able to stop the pictures at any point also aids in studying any given bit of action—something which is generally impossible with machines utilizing regular film.

By removing the lamp and substituting a small mirror as shown in the second illustration, the projector can be used by an individual for viewing a picture without going to the trouble of putting up a screen, darkening a room and making the necessary electric connections.

## Safety for the Linemen

ELECTRICAL linemen follow a vocation which is precarious even when surrounded by utmost safeguards, high-powered circuits involving extreme precaution by the workmen lest injury or even death result from immediate contact with electrically-charged wires. Obviously, the rubber gloves worn by linemen for handling high-voltage circuits should be able to withstand severe usage, frequent tests determining this factor. Such is the object of an apparatus designed by the U. S. Bureau of Standards, the device revealing the

(*Continued on page 415*)



Testing linemen's rubber gloves to preclude their breaking down under actual working conditions

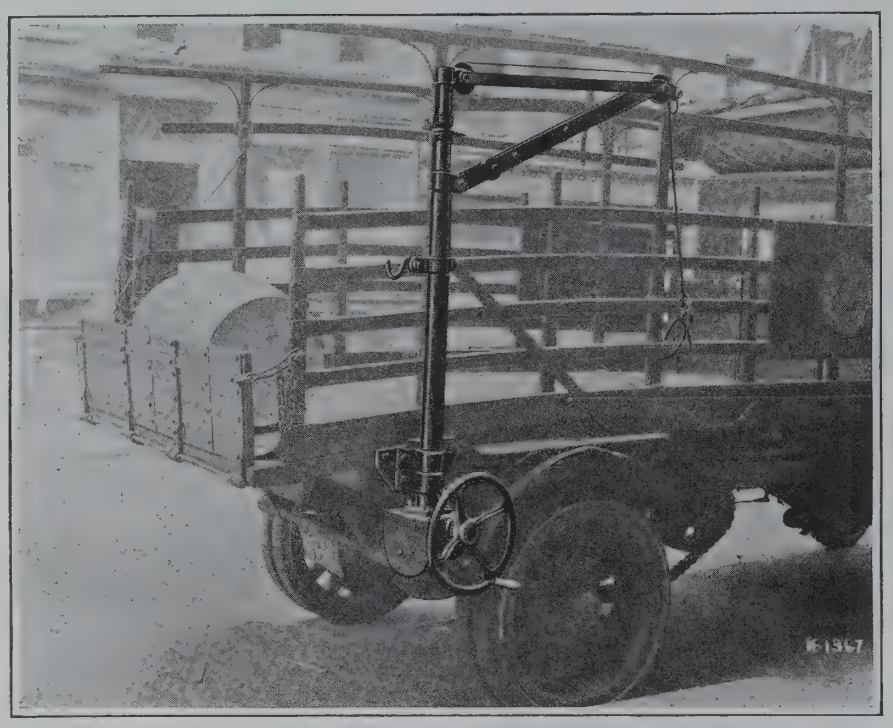
# The Motor-Driven Commercial Vehicle

Conducted by MAJOR VICTOR W. PAGÉ, M. S. A. E.

*This department is devoted to the interests of present and prospective owners of motor trucks and delivery wagons. The editor will endeavor to answer any question relating to mechanical features, operation and management of commercial motor vehicles*

## Simple Hoist for Trucks

THE problem of loading trucks with heavy objects is not an easy one to solve in a large city because it is not always possible to back a truck up to a curb and use skids on which heavy objects such as boxes, barrels or pieces of machinery can be raised from the street to the truck platform. A simple elevating crane which is shown in the accompanying photograph has been devised by a New York manufacturing concern to facilitate handling heavy objects. It is composed of heavy iron pipe which comprise the pillar and arms made of bar iron. The pillar is supported by clamp members and the portion carrying the iron arm may be swung to the rear of the truck and when the load has been elevated to platform height it may be moved over the truck bed and the load deposited thereon. The hoisting cable runs down through the center of the hollow pillar to a gear-actuated winding drum carried in the base casting. A large hand wheel with handle extension from the rim is provided so the winding drum may be operated by one man without great exertion. It will be evident that this simple fitting may be used to good advantage on any truck having a rack-side body and used for general transfer purposes. By its aid one man may easily load large boxes and barrels that would be a severe tax on the strength of several men if loaded in the usual manner.

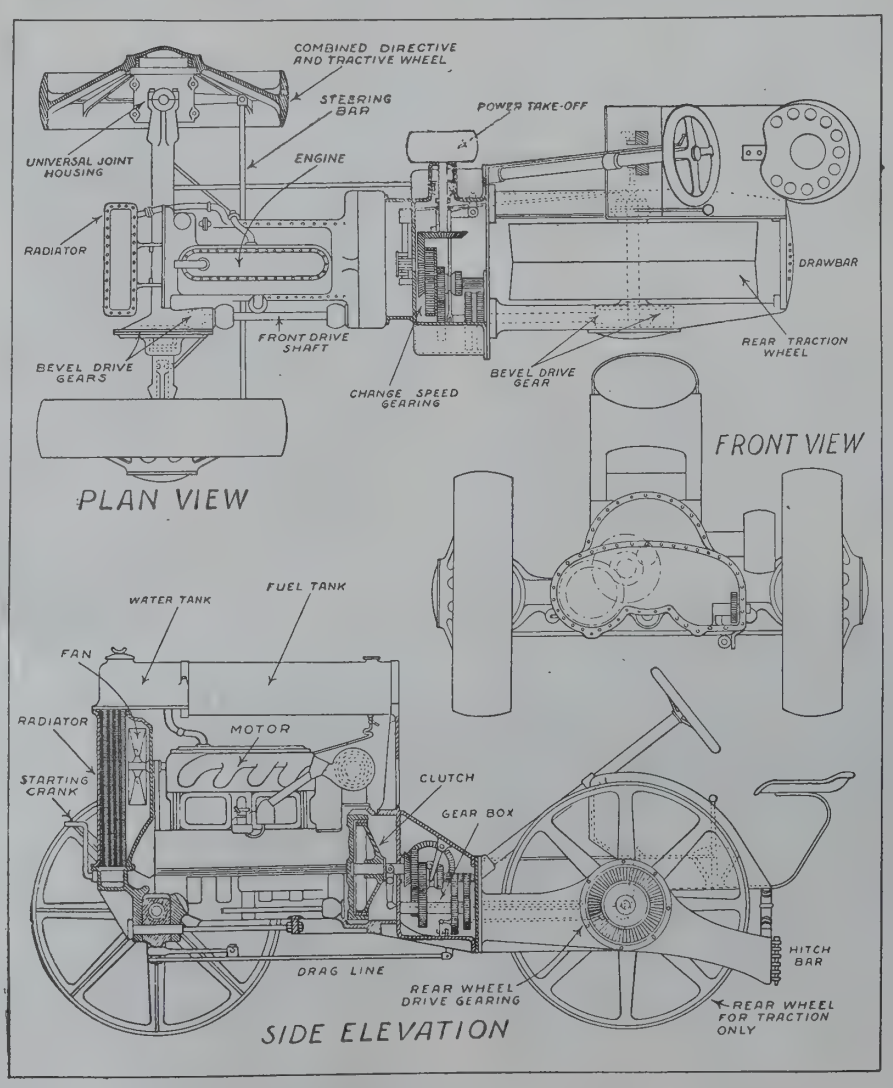


**This simple crane permits of swinging heavy loads on and off truck**

## New English Tractor

THE accompanying illustration shows a novel design of a three-wheel tractor for agricultural and road building use that has been devised by an English manufacturing company. In some respects the tractor follows late American practice inasmuch as it is the form that has no frame other than that provided by the engine base, gear box and extensions attached to the latter member to which the rear wheel is secured. Among the novel features of this tractor other than the adoption of the frameless system of design is the provision of power transmission mechanism to all three wheels. The two front wheels are combined directive and tractive members. The steering knuckles are exceptionally large and house in the universal joints by which the wheels are driven. The main drive from the change-speed gear case is by means of a double universally jointed shaft extending from the front end of the gear case to a differential housing on the front axle in which the main drive is by bevel gear reduction. The single rear wheel is operated by a shaft which carries a bevel pinion that engages the bevel gear on the wheel-supporting axle.

A power take-off is provided by which bevel gears transmit the power from the clutch shaft to a pulley at the side of the gear case to which a belt attachment can be made for driving any forms of machinery that would ordinarily be operated by belt power. The application of power to all three wheels of a light tractor is an attempt to secure maximum traction and the machine should have a greater effective draw-bar pull than any three-wheeled form of the same weight delivering the power only of one driving wheel, as is the usual construction when the three-wheel design is followed. The tractor illustrated shows clearly the influence of American practice; and the method of dispensing with the frame by using the engine base for that purpose, the incorporation of a clutch and change-speed gearing as a unit with the engine and also as part of the frame structure, and the support of the fuel tank and installation of the radiator, are all very evidently copied from a well-known American tractor design that was produced in large quantities during the war in both this country and in England. The tractor illustrated is distinctive in design, however, in the method of power transmission. The general features are so clearly brought out in the illustration that further description seems to be unnecessary.



**Details of a new three-wheeled tractor of English design**

## Motor-Truck Life

THE life of motor trucks has formed the subject of many articles. While most of the articles have been radiant with optimism, they were unfortified by fact for the very simple and sufficient reason that the fact was not available. Lately, the records of economy, efficiency and durability have been accumulating rapidly with the increasing care given to watching truck performance and it is now possible to substantiate many of the assertions of former years.

It is not an uncommon thing to read of the remarkable records of some quite old and certainly well worked machines. Those who used to argue for a scheme of depreciation based on an estimated useful life of 100,000 miles and who won little beyond scorn or good-natured toleration for their pains, now enjoy the satisfaction of seeing the proof presented in convincing form and volume One manufacturer has repeatedly drawn attention to the fact that numerous machines of his make have reached that mileage, while many others have exceeded it, some being still in service after more than 300,000 miles of economical travel. On an estimated average daily mileage of 50, which is very common in many lines of trade, this means, in the maximum case cited, a time-life of twenty 300-day years, or at least ten years, were the daily mileage as high as 100. Even a life of but 200,000 miles indicates a time-life of 13 years and 4 months at the rate of 50 miles a day. In such a case depreciation, considered as an annual rather than as a mileage charge, is no greater than 7.5 per centum instead of the 33 1/3, 25 and 20 per centum figures so frequently employed by operators.

## Mobile Shoe-Repair Shop

TWO special trucks built by a well-known Detroit manufacturer and especially equipped for the United States army as mobile shoe-repair shops, recently passed through New York on a test trip from Boston to Washington, D. C. The purpose was to show how easily such an outfit can be moved from place to place, what speed can be maintained and how it will stand up under a 500-mile road test. The first truck carries all the necessary machinery for remaking and repairing shoes, which is driven by a separate motor connected with the driving shaft of the standard stitching machine, the nailer, the scouring and finishing wheels. This motor also furnishes electric lights through a dynamo, and heating facilities are provided through registers connected with the exhaust.

The second truck is equipped as a supply depot, and carries all the materials for repairing soldier's shoes, such as sole leather, heel lifts, hob nails, tacks, welting and other necessary findings as well as extra machine parts for both the trucks and machinery. This supply truck can also be used to dispatch repaired shoes to various points along the lines where troops are located. Army officials estimate that approximately 800 pairs of shoes a day can be tapped when the mobile outfit is running with a day and night crew of seven men. There is also carried a complete set of apparatus to pull the trucks out of snow drifts or mud, consisting of ground anchor, winches, ropes, chains, picks, and shovels.

### Concrete and the Building Crisis

(*Continued from page 399*)

the concrete. From the ground level up, in the building we are describing, the same forms answer for each successive floor.

Generally, these forms are constructed of wood and have the surfaces contiguous to the concrete oiled so that they will strip readily and smoothly. The molds for the columns, however, are of sheet steel and composed of a number of segments held in place by suitable rings or straps. By omitting one or more of these segments it is practicable to use the same molds in casting the smaller columns for the upper floors. The actual progress being made in building this structure is a floor per week.

In some undertakings, buildings are reared by using sliding forms for the monolithic concrete walls, the forms moving upward as the material sets. This method of construction permits of continuous operation throughout twenty-four hours daily. Necessarily there is economy in form outlay. Reinforced concrete has been successfully employed in fashioning concrete roof girders having a span of fully 80 feet. Because a reinforced concrete building is fireproof, it is possible to obtain very low insurance rates, and this is an item not to be overlooked nowadays. Finally, it should be recalled that concreting in cold weather is entirely practicable, and work can be carried on satisfactorily the year through if certain precautions be taken to shelter the newly laid concrete from frost and to heat the sand, pebbles or broken stone, and water before mixing. And cement grows stronger with age—differing in this particular from a good many other structural materials.

### The Aerial Cruiser

(*Continued from page 400*)

control car and there is telegraph communication to all the other cars. The motive power consists of four engines, two in the machinery section of the forward car, and one in each wing car. Each engine develops a maximum of 230 brake horse-power at 1,400 revolutions per minute. The engines are six-in-line vertical, with overhead valves (two inlet and three exhaust per cylinder).

#### Supply Systems

The petrol is stored mainly in the keel corridor in 92-gallon vertical tanks. There are 34 tanks giving a total capacity of 3,128 gallons weighing about ten tons. Seventeen tanks may be readily slipped overboard to act as ballast.

#### Water Ballast

The water ballast is in two sections, one for emergency, the other for maneuvering. The emergency ballast bags discharge their whole contents when operated. The maneuvering bags may be liberated in any proportion at will. The weight of the emergency water is 2,000 pounds forward and 2,000 pounds aft. The four maneuvering bags have a capacity of 2,200 pounds each.

#### Armament

R-80 has been designed to carry the following armament:

- 8 230-pound bombs, stowed horizontally in the keel, and released electrically from the control car.
- 1 automatic quick-firing 2-pounder, and 1-cluster of two Lewis guns mounted on the top gun platform, forward.
- 2 Lewis guns in the tail gun position.
- 2 Lewis guns, one on each beam, in the forward control car, and
- 1 Lewis gun mounted in each wing car.

#### Accommodation

Separate quarters are provided in the keel for officers and men who are not on watch. The cabins have tables, chairs,

(*Continued on page 412*)

Wherever there's metal to be cut in the quickest possible time, and with the minimum waste of material, Starrett Hack Saws are on the job.

There's a Starrett Blade to suit any kind, size or shape of material. The Starrett Hack Saw Chart points out just which blade to use and how to use it. Choose the right blade, put it to work in the right way, and let it prove that Starrett Blades "cut quicker and last longer."

In these days of high production costs, every little leak shows up big in your running expenses. Let our new service book, "Hack Saws and Their Use," show you how to reduce your cutting costs to the minimum. Write for a free copy.

THE L. S. STARRETT COMPANY

*The World's Greatest Toolmakers*
*Manufacturers of Hack Saws Unexcelled*
ATHOL, MASS.

Use Starrett Hack Saws

### The Measure of Hack Saw Efficiency

Efficiency in the case of Hack Saws is measured both by the length of service and by the speed with which they cut. No purchaser, except one using an enormous number of blades, would ever dream of having his saws made to order, and so for practically all cases, the manufacturer determines what the saw shall be. He has the experience, the knowledge and the equipment which makes possible the manufacture of saws in the quality and quantity that are necessary to meet the many and diverse needs of industry. But his service to the purchaser is not complete unless he makes it possible for the latter to select instantly the particular saw best suited to the work in hand. Experience has proved that this may be most satisfactorily accomplished through the medium of a Hack Saw Chart based, not upon the characteristics of the saws, but upon the different materials which have to be cut in ordinary work, thus enabling the machinist to select always the proper blade by looking, not for the number of a blade, but for the name of the material he has to cut and employing the blade indicated under that heading on the chart.

As materials differ in texture of fibre, hardness and shape, so must the saws vary if we are to attain economy in the cutting-off department. When the right combination of saw and material has been made, the burden of responsibility rests upon the operator. It is his task to see that the greatest output is secured for the least cost for saws, labor, and overhead.

Economy is more than a mere reduction of first costs. As a matter of fact, consideration of first cost only usually results in inefficiency and an increased ultimate cost.—from *Hack Saws and Their Use*, published by The L. S. Starrett Co., Athol, Mass., for free distribution.

# Wire Rope—The Reclaimer

A watery, unhealthful, vermin infested swamp today, the richest farm land a year from today—the result of vision, enterprise, hard work, and the use of hundreds of feet of sturdy, dependable wire rope.

Miles upon miles of the most productive farm land owe their reclamation to wire rope. Operating on dredges and scrapers under most adverse conditions, wet, sandy, dirt incrusted, still they carry on, making it possible to produce valuable crops where disease and crocodiles bred before.

No task seems too great for wire rope—and none too unusual; for the scope of its usefulness broadens every day. But wire rope that is suitable for one purpose is not necessarily suitable for another. Each use makes certain demands upon a rope that must be met in a certain definite way.

The Broderick & Bascom Rope Co. makes wire ropes of different grades and characteristics suitable for all purposes. Each, in its proper place, will give the most service for the least money.

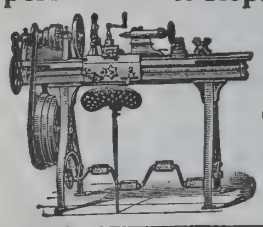
B. & B. Yellow Strand Wire Rope, with one strand of Yellow to distinguish it, has no peer in strength and wearing quality.

**BRODERICK & BASCOM ROPE CO., ST. LOUIS, MO.**

Factories: *St. Louis and Seattle* Branches: *New York and Seattle* Warehouses: *St. Louis, New York, Seattle*

Agents in every locality C437A

**For Gunsmiths, Tool Makers, Experimental & Repair Work, etc.**



From 9-in. to 18-in. swing. Arranged for Steam or Foot Power, Velocipede or Stand-up Treadle.

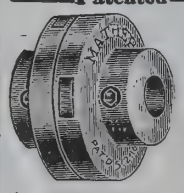
**MATHER FLEXIBLE COUPLING**

Patented



Designed and built to solve the specific needs in connection with small motors and light loads. Combines Flexibility, Strength, Lightness, Simplicity and Absence of Noise. It allows maximum freedom in either vertical or horizontal movement. Write for full details.

CHARLES BOND COMPANY
617 ARCH ST. PHILADELPHIA, PA.

**Weber Crank-Pin Re-Turning Tool**

**No Filing**
**No Offsetting**
**No Jigs**

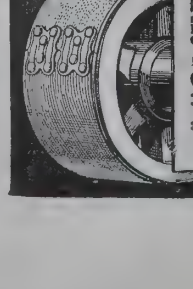
This Weber Tool turns all pins absolutely round from one setting of Crank Shaft, on centers. A micrometer dial enables the operator to gauge his cuts and turn all pins to uniform size. The average time required for trueing up one pin is from 5 to 10 minutes. The 4 pins can easily be finished in 30 minutes, and the entire shaft is completed with only one setting.

**The Weber Tool is guaranteed** to turn crank-pins within as close limits of accuracy as any other known method. It will soon save its cost in any Tractor or Automobile Repair Shop. An assortment of cutting tools are furnished. These will fit the pins of most of the popular automobiles, trucks and tractors. Write for Circular and Prices.

**SAWYER-WEBER TOOL MFG. CO.**
353 S. Alameda St. Los Angeles, Cal.

**CRESCENT BELT FASTENERS**

"Make Good Belts Give Better Service"



A BELT is no better than its joint. A weak, inefficient joint means a weak, inefficient belt. Use Crescent Belt Fasteners and give your belts an honest-to-goodness chance to "make good". No holes punched. No belting cut away. Full strength sustained. Crescent joints HOLD. Re-making of belt joints eliminated. Continuous production insured. Send for Booklet B on Increasing Belting Efficiency.

**Crescent Belt Fastener Co.**

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

## Electrical Devices

EMERGENCY LAMP.—W. J. KOENIG, deceased; address Ralph De Ross, 410 E. 29th St., Brooklyn, N. Y. In order to adapt this lamp for use about machine shops, engine rooms, automobiles or the like it is provided with an electromagnet serving to hold the lamp automatically in any desired position on or against any metallic support. The magnet circuit is a branch of the lighting circuit, and the magnet is energized while the lamp glows.

## Of General Interest

VEGETABLE PEELER.—J. H. HAMLIN, 430 11th Ave., New York, N. Y. Among the objects of the invention is to provide a vegetable cutting and peeling implement adapted to easily and quickly remove the peeling of a potato without waisting that part directly beneath the skin. Another object is to provide a hand-operated implement having a self-contained reservoir of water to flush the surface of the vegetable being peeled, and to provide an abrasive implement with sharp points for removing eyes or faulty portions of the vegetable.

EVER-SET CAGE TRAP.—H. ROHLFF, 332 W. 2nd St., Davenport, Iowa. The invention has reference more particularly to a self-operated ever-set wire cage trap which is especially adapted for trapping birds. The prime object is to provide means for trapping and confining birds without injury. A further object s to construct the trap so that there will be no chance for the birds escaping, yet the trap entrance is always set and capable of operating an unlimited number of times without attention.

RECEPTACLE COVER.—A. SWENSON, 141 Valley Brook Ave., Lyndhurst, N. J. This invention relates to receptacles for holding sugar, fruit or other articles of food. Among the objects is to so construct a cover for this type of receptacle that it may be readily removed from the body in order that all parts may be thoroughly cleaned, thus rendering the article sanitary.

WASHBOILER.—A. T. TIMOSCI, 668 Willis Ave., N. E., San Jose, Cal. The object of the invention is to provide means in connection with wash boilers of usual construction, for supporting the garments to be washed above the bottom of the boiler, the support being arranged in such manner that the garments will be held loosely on the support, and in such manner that the cleansing fluid may flow inward with respect to the support and garments.

WINDOW SEAT.—D. F. CROWE, 1554 Ligonier St., Latrobe, Pa. The invention has for its object to provide a device of the character specified, capable of being seated upon the sill of a window in such position that one seated in the seat may have access to the outer face of the window sashes of the window without danger of falling.

ASH RECEIVER AND SIFTER.—P. H. CHILDRESS, Box 317, Waynesboro, Va. The primary object of the invention is to provide an ash receiver and sifter which will sift the ashes as they are discharged from the grate bars thereby separating the cinders from the ashes, and retaining the cinders in one receptacle and the ashes in the other, to provide for convenient and ready handling.

ANTI-FRICTION BUFFER.—L. LARSEN, Apartado, 150 Tampico, Mexico. The invention relates more particularly to an anti-friction buffer for docks, wharves, ferry slips, ships and the like, which is adapted to absorb the shock of the impact when a ship is being docked, or when two or more ships are lashed together for towing, the object being to prevent damage to the ships from friction.

STORE COUNTER.—F. H. COLE, Yuma, Colo. The invention has for its object to provide a store counter especially adapted for use in grocery stores, for making up orders, wherein the counter has a series of compartments, each provided with a sliding cover arranged to be slid to one end and stood in vertical position, the covers bearing the names of the customers whose order are to be filled.

HOLDER FOR CARBON SHEETS.—W. S. FREEMAN, 55 Worth St., New York, N. Y. The object of this invention is to provide a device consisting of a cap so connected with the end of the sheet that sheets of paper may be arranged on the opposite sides of the carbon sheet with their ends in the cap, to permit the instrument to be written and the carbon copy made while the sheets are so held, a second cap being provided for enclosing the folded sheet and carbon for protecting the same.

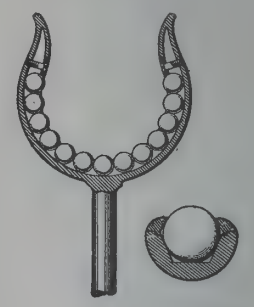
## Hardware and Tools

DOOR HANGER.—B. SPITZFADEN, c/o Elevator Efficiency Co., 51 Maiden Lane, New York, N. Y. The invention relates more particularly to ball bearing hangers for heavy doors. The general object is to meet the severe conditions by providing a construction of parts that will resist heavy strains and at the same time will maintain the door in proper alinement against all tendency to become loose.

STOVEPIPE LOCK.—G. W. HORMEL, 115 N. Wabash St., Wichita, Kan. The invention relates to locks for securing stovepipe lengths together. An object is to provide a simple and effective lock for positively uniting the meeting ends of adjoining stovepipe sections by means of a movable locking member which engages with a stationary member.

WINDOW LOCK.—D. SPIVAK, Room 406, Chamber of Commerce Bldg., New Haven, Conn. Among the principal objects of the invention are to provide a lock of the character mentioned which may be placed in service to provide for window ventilation and secured in such a manner as to prevent tampering with the lock, and to provide a lock the cost of production of which is small.

ROWING GEAR.—D. MCRAE, Central Islip, N. Y. The invention relates more particularly to rowing gear in the form of oar locks, which will reduce the friction incurred by the oar when making the stroke or feathering, the oar lock as constructed having a groove



A FRAGMENTARY VERTICAL SECTION AND DETAILED VIEW

formed in the inner face of the stirrup, and anti-friction members arranged therein, and means for retaining said members in the groove, the anti-friction members constituting a bearing surface for directly receiving an oar.

CLAMP BOLT.—E. J. RUQUET, JR., 1637 Richmond Road, Stapleton, S. I., N. Y. In ship and bridge building, it is often necessary to employ temporary means for holding plates together while the permanent rivets are being driven. The present invention provides a temporary bolt clamp for this purpose. The clamp is simple in its application and may be applied or removed very quickly.

DOOR SPRING.—J. A. CAMPBELL, Carbondale, Ill. This spring is of the type adapted to be concealed within the frame of the door and jamb. It automatically tends to keep the door in a normally closed position and limits to a predetermined degree its outward swing when pushed open. It aso locks the door in its extreme open position.

WELL DRILLING TOOL.—W. A. MCCAUSLAND, 4072 Jenkins Arcade Bldg., Pittsburgh, Pa. The present invention is an improvement in a construction disclosed by Mr. McCausland's previous patent No. 1,211,198. The improved feature of the invention lies in the construction of the stem or middle section of the drilling tool, which includes a tube having a filler with a member embedded therein, the ends of said member projecting beyond the ends of the tube to provide anchoring means whereby the stem is secured to the drill jar and bit respectively.

## Heating and Lighting

FLUE EXTRACTOR.—P. M. CANTY, 909 6th Ave., Altoona, Pa. An important object of the invention is to provide a flue extractor which will so effectively and powerfully engage the flue that the enormous pulling force

necessary to withdraw the flue may be applied. Another object is to provide gripping elements of strong and durable structure, with means for positively withdrawing the gripping elements from engagement with the flue when desired.

TUNNEL KILN.—F. J. LEISEN and E. S. DUNN, 1229 3rd Ave., Huntington, W. Va. The invention relates particularly to the type of kiln known as a tunnel kiln, wherein the articles to be burnt are mounted upon movable carriers, these carriers being intermittently advanced through the kiln and subjected to various degrees of heat so that each carrier with its load enters one end of the tunnel with dried material, and emerges from the opposite end with the burnt articles, which are then subjected to cooling drafts to permit of their rehandling.

SOLAR STEAM GENERATOR.—A. V. FOLSOM, 1121 E. 42nd St., Jacksonville, Fla. An object of the invention is to provide a solar steam generator the principal features of which consists of suitable means for containing water, disposed in such a way as to be heated by means of the rays from the sun through the instrumentality of a reflector for concentrating the rays thereon, means also being provided to turn the reflector in such a way as to always keep it facing the sun.

### Machines and Mechanical Devices

COIL WINDER.—L. F. STRATTON, 21 W. 5th St., Charlotte, N. C. The primary object of this invention is to provide a coil winder by which coils of various sizes and designs may be wound. The invention furnishes a comparatively cheap and simple device which is capable of various adjustments on which the wire may be coiled in a most convenient and practical manner.

CENTRIFUGAL ORE SEPARATOR.—J. A. RICE, Berkeley, Cal. This machine is especially adapted to separate such materials as mineral particles from mill dust, from flue dust, or bag house products, digerent minerals constituting concentrates, liquids differing in specific gravity, and gases such as furnace gases from smelters, where it may be desirable to extract finely divided dust particles, or to separate two gasses differing in specific gravity.

### Medical Devices

MEDICATED PESSARY. — MARTOCCI-PISCULLI, 235 2nd Ave., New York, N. Y. Among the objects of the invention is the construction of a pessary which shall be entirely self-contained, which may be made of any suitable material, and which will have incorporated in it means permitting an evaporable germicidal agent to be associated with it.

### Prime Movers and Their Accessories

AUTOMATIC GOVERNOR.—F. J. BRUMME, Cooksville, Ill.—An object of the invention is to provide an automatic governor designed to be attached to certain portions of an internal combustion engine and actuated by the operation thereof, whereby the flow of fuel through the carburetor is automatically controlled, and can be adjusted at will while the engine is in motion. The device is compact in form and takes up little space.

INTERNAL COMBUSTION ENGINE.—T. B. CASEY, 306 Sewell Apt., Vallejo, Cal. The invention has reference more particularly to means for introducing a scavanging medium in the combustion chamber to effect a complete exhaust of all spent gases incident to the firing of the explosive charge, and thus render the combustion chamber better adapted to receive and fire the explosive charge, whereupon the engine will be capable of operating with a higher degree of efficiency.

VAPORIZER FOR HEAVY OILS.—C. C. MANKER, Mayfair Apts., 40 St. James St., Los Angeles, Cal. This vaporizer for heavy oils such as kerosene and the like, is adapted to be attached to an automobile to furnish the motive power for the same. Means are provided for automatically regulating the quantity of the vaporized products. The oil vapor is mixed with steam which eliminates carbon deposits from the interior of the engine.

### Railways and Their Accessories

SWITCH ADJUSTMENT HOUSING.—R. R. BAKER, 7758 Lagoon Ave., Chicago, Ill. An object of the invention is to provide a housing for switch adjustment that is simple in construction and operation and not liable to easily get out of order. A further object is to provide a casing to prevent snow or sleet from clogging the adjustable connections and preventing adjustments being made until such snow or sleet is removed.

SWITCH LOCK.—P. H. MYERS, c/o Sanatorium, Hainburg, Pa. The invention aims to provide a device by means of which when the point of a switch has once been thrown it would be impossible for this point to shift subsequently unless directly operated by some outside agency. The switch lock is so constructed that it may be operated entirely by mechanical means.

### Pertaining to Recreation

GAME.—H. M. THOMPSON, R.F.D. No. 12, Brownsville, Me. The object of this invention is to provide a device having a game board in the form of a map of some specified country, provided with route lines and with stops indicated on the lines, together with markers for indicating progress along such route lines, the progress of the counters being determined by game pieces, as, for instance, dice.

ROCKING HORSE.—W. DICKINSON, 608 W. Sharpe Ave., Spokane, Wash. The invention has for an object to provide an article of furniture for the use of children. A detachable seat is provided which may be secured to the arm of a rocking chair, an upright formed to simulate the head of a hobby horse, and a clamp for securing the seat to the arm of the chair so that when not in use the device may be removed.

### Pertaining to Vehicles

SLEIGH RUNNER ATTACHMENT FOR BABY CARRIAGES AND OTHER VEHICLES.—H. FLECKL and W. J. BOYD. Address Hans Fleckl, Boyds, Wash. The invention provides a sleigh runner attachment particularly adapted to be attached to a baby carriage. The runners may very quickly be raised to permit the carriage to run on its own wheels or be moved down into engagement with the snow or ice, lifting the wheels from the frozen surface.

VEHICLE WHEEL.—C. E. P. JULIEN, 41 Boulevard Haussman, Paris, France. The invention provides an additional wheel rim applicable to all kinds of vehicles but intended more particularly for tractors, agricultural machines and any motor vehicles required to travel over hard roads and soft ground. The auxiliary rim is provided with V-shaped projections which will project into the ground when traveling over a soft surface but which will not contact with the ground when traveling over a hard surface.

TOOL FOR USE IN REMOVING AND REPLACING TIRES.—V. H. MANKEY, 1110 So. Kline St., Aberdeen, So. Dak. The prime object of the invention is to provide a tool whereby the rim can be quickly displaced or restored in a manner to minimize the possibility of injury to the rim. A further object is to provide a tool that may be quickly placed in position gripping the respective ends of the rim and then the clamps be relatively moved through the medium of an ordinary wrench so that the displacing of the rim or the restoring of the same can be effected in a few minutes.

AUTOMATIC CLUTCH DIFFERENTIAL ESPECIALLY FOR MOTOR CARS.—R. W. A. WARREN, Katanning, West Australia, Australia. The invention relates to an automatic friction clutch differential, which is designed to make use of the considerable centrifugal force or momentum of the car and passengers under which, when turning a corner, the car body and consequently the axle housing tends to continue in a straight course rather than to move with the wheels in the new direction.

PIPE LOCK.—E. BAKLEY, R.F.D., Chatham, N. J. The invention relates to a device for locking a pipe through which fluid is adapted to flow, so as to prevent the passage of any fluid. It is especially constructed for use in connection with an automobile to prevent the theft of the same by cutting off the connection between the gasoline tank and the carburetor but in such a manner that it may be instantly opened by the owner without the use of any special key.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

Design-time and Production costs 75% Metal costs 25%

**You pay 100% for service**
***. . . and but 25% for the metal that will measure its life***

YOU get the service paid for . . . uninterruptedly, or in installments—with repeated renewals or repairs as the metals used stand up to the work.

Economically then, metals used in parts manufacture assume greater value than just 25% of apparatus costs.

Monel Metal, used in power plant apparatus as valve trim, turbine blading, pump rods and liners, etc., where resistance to high heats, erosion and corrosion is vital to service delivery, has more than justified its cost both as raw material and finished product. For the manufacturer by employing Monel has purged his apparatus of weaknesses that compel expensive repairs, costly shutdowns, and repetitive purchases of new machines.

The very toughness of Monel that in some cases will slightly raise manufacturing costs is pledge of its ability to deliver service continuously.

The name Monel is given to a line of metal products produced by The International Nickel Company from a natural nickel alloy—67% nickel, 28% copper and 5% other metals. These products include Monel blocks, Monel rods, Monel castings, Monel wire, Monel strip stock, Monel sheets, etc. The name Monel identifies the natural nickel alloy as produced by The International Nickel Company.

Monel Metal is absolutely untouched by rust, is strong as steel, resists the eating action of most alkalies and acids. Monel retains its strength under high heats that break down the very structure of most metals and successfully withstands the eroding action of high pressure and superheated steam.

THE SHOE THAT HOLDS ITS SHAPE

$7.00 $8.00 $9.00 & $10.00 SHOES

FOR MEN AND WOMEN

YOU CAN SAVE MONEY BY WEARING W. L. DOUGLAS SHOES

The best known shoes in the world. They are sold in 107 W. L. Douglas stores, direct from the factory to you at only one profit, which guarantees to you the best shoes that can be produced, at the lowest possible cost. W. L. Douglas name and the retail price are stamped on the bottom of all shoes before they leave the factory, which is your protection against unreasonable profits.

W. L. Douglas $9.00 and $10.00 shoes are absolutely the best shoe values for the money in this country. They are made of the best and finest leathers that money can buy. They combine quality, style, workmanship and wearing qualities equal to other makes selling at higher prices. They are the leaders in the fashion centers of America. The stamped price is W. L. Douglas personal guarantee that the shoes are always worth the price paid for them. The prices are the same everywhere; they cost no more in San Francisco than they do in New York.

W. L. Douglas shoes are made by the highest paid, skilled shoemakers, under the direction and supervision of experienced men, all working with an honest determination to make the best shoes for the price that money can buy.

W. L. Douglas shoes are for sale by over 9000 shoe dealers besides our own stores. If your local dealer cannot supply you, take no other make. Order direct from factory. Send for booklet telling how to order shoes by mail, postage free.

CAUTION.—Insist upon having W.L.Douglas shoes. The name and price is plainly stamped on the sole. Be careful to see that it has not been changed or mutilated.

# RELATIVITY

## The Special and the General Theory

By Professor Albert Einstein, Ph.D. LL.D.

Translated by Professor Robert W. Lawson, M.Sc.

THE Einstein law has been accepted by astronomers and physicists as an epoch-making discovery. Up to the present Newton's law of gravitation has been universally accepted, but the new theory goes farther, and, apart from supplying the laws of Newtonian mechanics when certain approximations are made, it enables us to predict the exact course of all motions resulting from gravitation. In this book, which is a popular exposition written for the average reader, Professor Einstein explains his famous theory which has so excited the scientific world. This volume is intended primarily for those readers who, though interested in the trend of modern theory, are not conversant with the mathematical analysis used in theoretical physics. The author's aim has been to give an exact insight into the theory of relativity, and to present the main ideas in the clearest and simplest form. He has succeeded admirably, and those who desire an authoritative and understandable explanation of the Einstein theory will find it between the covers of this book.

## The Aerial Cruiser

(*Continued from page 409*)

etc., and the sleeping accommodation consists of hammock bunks. Meals are cooked in special cookers heated by the exhaust from the engines.

### Streamlining and Efficiency

The most careful attention has been given to the design of the cars with the result that a great increase in aerodynamical efficiency has been obtained over the cars of R-33 class airships. By making all the cars of the best known streamline shape, the head resistance as compared with R-33 class cars has been reduced by over 60 per cent, and the utilization of the fine nose of the control car as an observation station for the use of the navigating officer gives exceptional facilities for groundwork, which are not obtained in other designs.

The cars themselves are designed on a principle which enables the weight, as compared with similar cars of R-33 type to be cut down by over 50 per cent with greater strength and rigidity of structure. More roomy cars are therefore provided, the beam of the control car being eight feet as against a maximum of six feet on R-33 class.

### Mooring

Costly experience in the early days of the Zeppelin experiments showed that the greatest peril to the airship occurred when it came near the earth, and several years ago the SCIENTIFIC AMERICAN pointed out that some form of mooring post to which the dirigible could make fast was necessary if landing disasters were to be avoided. The problem has been very ably worked out in the Vickers mooring gear, and R-80 carries in her nose the necessary gear for sailing up to one of these posts and making fast. A covered gangway can be thrown across from the moored airship to the mooring post through which the passengers pass to elevators arranged within the post. Gas, oil and water pipes form a permanent part of the mooring-post equipment, and they are provided at their upper ends with suitable connections for supplying the airship.

## Preventing Rust at High Temperature

(*Continued from page 404*)

shapes, lengths and sizes. Straight pipe ⅛ inch to 18 inches diameter has been calorized in lengths up to 20 feet. There is no limit to the size of material which may be treated. Calorized steel is particularly adapted to pyrometer protection tubes because of the high temperature to which they are exposed. Not only is it cheaper than any of the chrome steel alloys which have at times been offered for this purpose, but it possesses other advantages.

Perhaps the largest and most easily developed field for calorizing lies in its application to the various pots, boxes, tubes, retorts, and special equipment employed in the many heat treating processes. A large quantity of the above mentioned articles have been successfully calorized, their average life being over eight times that of the uncalorized equipment, resulting in a great saving. A notable feature is that calorizing can be applied to any of this equipment without necessitating change in its design or construction.

Many furnaces, kilns, ovens and retorts employed in various manufacturing processes were originally made of iron or steel. This metal has a limited heat-resisting quality and was reduced to scrap in a short time. It was repeatedly replaced, its life being short because of the excessively high temperatures and the same performance continued indefinitely. As the price of the metals increased, the use of the other materials was considered by engineers in an effort to reduce costs. They built these furnaces from fire-brick and various refractory materials. In a great many instances these materials were used at a loss of

PYORRHOCIDE
POWDER
ANTISEPTIC
*for Pyorrhea prevention*

**Gums that bleed easily—**
that are soft and sensitive—warn you that pyorrhea is developing. Loss of teeth will surely follow unless pyorrhea is checked or prevented. Dental clinics, devoted exclusively to pyorrhea research and oral prophylaxis, have *proved* the specific value of Pyorrhocide Powder for restoring and maintaining gum health. It is prescribed by the dental profession for pyorrhea treatment and prevention. It keeps the gums healthy and the teeth clean.

Pyorrhocide Powder is economical because a dollar package contains six months' supply. Sold by leading druggists and dental supply houses.

**FREE SAMPLE**
*Write for free sample and our booklet on Prevention and Treatment of Pyorrhea.*

25 to 75 per cent efficiency, but were adopted because the repair costs on iron and steel were prohibitive. Calorizing can be applied to metal furnace lining, baffle plates, etc., the cost of these calorized plates per unit of service being in a great many cases much less than that of refractory materials. There is an unlimited field for calorizing as applied to equipment of this nature.

There are many possible applications of calorized metal which have not been considered, for the reason that only within the last six months has calorizing been available to the commercial world. It is impossible to enumerate or describe in detail the great number of applications. Every plant presents its individual problem and it is the object of the writer to illustrate several applications with the idea of suggesting to the engineer, metallurgist, and plant manager, possible applications to special equipment used in his particular process of manufacture.

## A Pocket Machine Gun

(*Continued from page 405*)

obliged in his work to sit behind various machine guns in erosion, function, and ballistic tests for a matter of six months or more, and he was not impressed at the end of this time with the reliability of function of any machine gun at present used by civilized armies, examples of which we tested. Used under the most favorable conditions, in the hands of skilled mechanics, they all were made to look simply childish in certainty of function and endurance when compared to that other gas engine—the motor of the small car. A stoppage, a broken part, a jam—one of the three would occur with the most reliable machine gun of them all, the Browning, about every 1,000 rounds fired.

One thousand impulses of any given cylinder in the auto motor will, in high gear, run the little car something like a mile, and a hundred-mile run means that each cylinder has fired a hundred times as many "shots" as the machine gun averages between bits of trouble. Not even the most pessimistic of car owners will deny that the motor will run the car a hundred miles without stop, jam, or break.

I cheerfully admit the difference in conditions, such as the far greater pressure of the machine gun and the higher speed of the parts; but still I believe that there is not enough difference in conditions to justify the wide difference in reliability between the two types of gas engines. Possibly, therefore, the decision of the latest entrants into the machine gun market to use lubrication is based on sound judgment. There is also the possibility that they are making a virtue out of a necessity.

The new gun is arranged to fire any pistol cartridge, the change necessary being merely in barrel, magazine and bolt-head. Special cartridges containing buckshot will also function the gun, and make for close-up work a tremendously effective weapon.

The writer, after firing the gun several hundred rounds, would class it as the equal of a score of average policemen firing as the average policeman fires, provided of course the gun were fired by a man accustomed to it. And of course it is far easier to train one man to become expert with the gun than it is to raise the shooting of twenty policemen to the expert stage with their pistols.

There would be no trouble whatever for one man firing the gun to sweep a street clear from curb to curb, but after all, its greatest strength lies in its moral effect. Killing many of the common American sort of mob is unfortunate unless the right ones can be selected for the slaughter. Mobs as a rule are composed of ten per cent vicious (the leaders), and ninety per cent fools. Wherefore the dispersing of the crowds without bloodshed is usually desirable. It would be a most vicious and determined

# Make This Test

## Watch how your teeth respond

This ten-day test has shown to millions the way to whiter, safer teeth. It is a free test—you should make it. No other method known can do what Pepsodent does for teeth.

### To end the film

The object is to fight the film, which dims the teeth and causes most tooth troubles. Dental science has worked years to do that.

Film is that viscous coat you feel. It clings to teeth, enters crevices and stays. The ordinary tooth paste does not combat it satisfactorily, so brushing leaves much of it intact.

It is the film-coat that discolors, not the teeth. Film is the basis of tartar. It holds food substance which ferments and forms acid. It holds the acid in contact with the teeth to cause decay.

Millions of germs breed in it. They, with tartar, are the chief cause of pyorrhea. Thus all these troubles have been constantly increasing, despite the tooth brush.

### Now we combat it

Dental science, after years of searching, has found ways to combat film. High authorities have proved them by clinical and laboratory tests.

The best dental opinion now approves these methods. Leading dentists everywhere are urging their adoption. Millions of people, as a result, now employ them daily.

The methods are combined in a dentifrice called Pepsodent. And a 10-Day Tube is offered free, so all who will may quickly know how much it means to them.

## Five Much Desired Effects

One ingredient of Pepsodent is pepsin. Another multiplies the starch digestant in the saliva to digest the starch deposits which cling and form acid.

It also multiplies the alkalinity of the saliva, to neutralize the acids which cause tooth decay. Two factors directly attack the film. One of them keeps teeth so highly polished that film cannot easily adhere.

Pepsodent combines the best that modern science knows to combat the great tooth destroyers. It has brought a new era in teeth cleaning.

### Watch it act

Send the coupon for a 10-Day Tube. Note how clean the teeth feel after using. Mark the absence of the viscous film. See how teeth whiten as the film-coat disappears.

You will see several new effects, and the book we send will tell you what they mean. This is too important to forget. Cut out the coupon now.

## CONDITIONS FOR THE $5,000 PRIZE EINSTEIN ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Essay Editor will cast the deciding vote.

aggregation that would stand up to the fire of one of these guns, after a couple of bursts had been fired over their heads or into the street in front of them. Moreover, one of the guns, mounted on a patrol wagon or automobile would riddle a car attempting to run by or to escape via the stern-chase route.

The cartridge selected for this gun is a most formidable one. Its bullet of 220 grains is 80 grains heavier than the bullet of our service rifles and machine guns, and its caliber, .45, as compared to .30 ensures that when it hits, it will strike a knock-down blow. The low initial velocity, less than a third that of the service rifle, and the stubby form of the bullet prevents it from having much range; which lack of carrying power is a most desirable thing in settled communities. The Ballistic Station found the extreme range of the cartridge to be 1,400 yards, with 500 yards as probably its effective range.

The locking bolt of the arm is worthy of notice as embodying a new principle in machine gun and self-loading arm mechanism. It consists of a wedge, sliding nearly vertical, and locking the barrel extension and receiver together. Its slots are cut at an angle of about 80° with the axis of the barrel and its extension. It was found years ago by Commander Blish of the United States Navy, the inventor of the device, that a wedge so arranged would hold while the breech pressure of the exploding cartridge remained high, but the instant or as soon as the bullet left the muzzle, the adhesion between wedge and its slots ceased, and the remaining backward pressure would compel the wedge to slide downward and unlock the breech mechanism. The principle applies to other forms of breech mechanisms, where the locking is done by cams without a final bearing at right angles to the line of backward thrust.

Thus, some years ago, a coast defense gun, firing blank cartridges, giving of course low pressure, insisted upon unlocking itself and coming open each shot.

This was very alarming because it was apparent that if the breech would cam itself open during the firing of low pressure blanks, then fireworks and trouble could surely be expected when firing high pressure service charges.

On trial, however, it didn't work out, the gun stayed locked beautifully with the service and high pressure charges. Here evidently the adhesion of the locking surface set up by the high pressure charge did not free in time to permit the subsequent falling pressure to unlook the gun and open it.

The writer found the same phenomenon when testing a well-known sporting rifle with greased cases. This rifle has a locking bolt which works in slots cut at nearly right angles to the horizontal bolt. The finger lever operating the mechanism normally has a catch to hold it closed, but here the catch was broken, the parts were worn and free and the case itself was greased.

The result was that the horizontal bolt would open during the firing, drawing the fired case with it. It did not "blow" open, that is it did not open during the height of the pressure and permit the escape of gas; it came open when the pressure had evidently fallen enough to free the locking surfaces of the vertical bolt, and permit the little remaining pressure to drive the breech bolt backward. The Ross sporting rifle was another weapon which would at times perform this trick if the rocker arm on the sear, which normally holds the sleeve closed, were removed, or was too short to reach up on the pulling of the trigger and hold the sleeve from backward movement. In this case, particularly with the cartridge case greased, the sleeve would slide open, taking the case with it. This was not a violent action, and there was no evidence of high pressure or gas. It was evident that when the gas pressure in the chamber fell, the bolt would cam open, just as did the interrupted-screw block of the coast defense gun referred to.

In the Submachine Gun, the joint invention of General John T. Thompson, retired, former Chief of the Small Arms Division during the war, and Commander Blish of the Navy, this same principle is used, the wedge locking bolt holding firmly while high pressure persists within the chamber, unlocking when the pressure falls, and permitting the bolt to slide back and the various parts of the mechanism to function.

It is question how much friction enters into this sort of locking arrangement, and therefore how much of the oiling system adopted is a matter of necessity.

The fact remains that the gun functions at extraordinary speed and with more than normal machine gun reliability. With its small size, its light weight, its tremendous rate of fire, and its ease of control, the recent New York acquisition is probably the most efficient man killer of any firearm yet produced. A well-known American factory is producing 15,000 of them—destination and purpose not announced.

## What Science Did for Cheese

(*Continued from page 406*)

record although much of this native product was of low grade. With the perfection of new commercial system of cheese manufacture, not only is dairying promoted in sections of the country far from city markets and adequate railroad transportation, but the standardization of Swiss-cheese-making also promises that we will produce our potential supplies at home and also may devote considerable of our surplus to export trade. At present one plant in California is manufacturing Swiss cheese on a large scale according to the new system of production. This factory will produce over $2,000,000 worth of Swiss cheeses this year while it has already exported two carloads of the product to Switzerland where the cheese was sold on the open market and was complimented as being better than the best of the domestic offerings.

Another notable accomplishment of the National Dairy Division has been the perfection of modern methods of Roquefort cheese production so that this delectable delicacy can be made from cow's milk and cured under artificial conditions, the finished product being as good as, if not better than, the expensive, imported Roquefort which comes from France and is made from sheep's milk. For twenty centuries, Roquefort has ranked as the king of all cheese. It has been made by the peasants of southern France who live near Roquefort and maintain approximately 500,000 sheep especially for the production of milk from which to make the cheese. During their six months' lactation period some of the ewes produce enough milk individually to make 50 pounds of cheese. The cheese, for the most part, is made on the farms and small factories of that neighborhood and subsequently sent to Roquefort where it is cured in the famous caves of that region—formed by the slipping of rock at the base of the Cambalou Mountains.

Currents of cool moist air circulate freely through the caverns and galleries and are aided in their natural refrigeration and curing of the cheese by the numerous streams of mountain water which wind hither and thither among the grottos. When the moist air currents strike the rocks, rapid evaporation occurs which is invaluable in lowering the temperature to about 40 degrees Fahrenheit. During recent years some of these natural subterranean ice-boxes have been enlarged and equipped with artificial means of refrigeration so that even lower temperatures than naturally obtain can be produced. The fact that cheese is produced at country points and concentrated at Roquefort

# Goblin *Does* Work Wonders!

**Goblin is a soap that really cleans; you can actually see the dirt disappear before your eyes.**

**It is made of the purest and most effective ingredients; that's why—it cleans thoroughly and quickly; lathers freely in the coldest or hardest water; does not injure the tenderest skin.**

**It's the heavy duty soap for the stained and badly soiled hands; —always keep a cake of Goblin on hand.**

# CHALFONTE

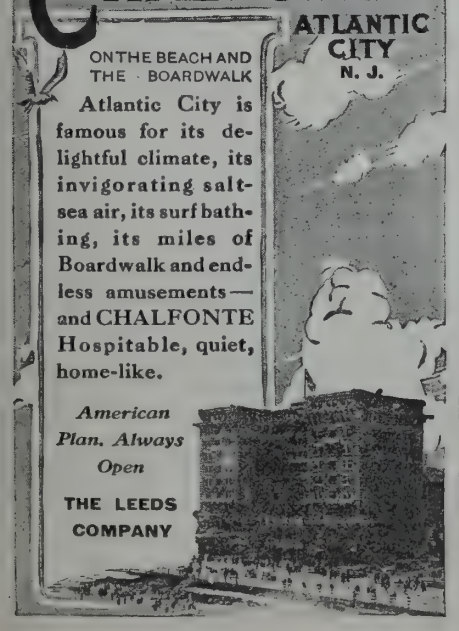
ATLANTIC CITY N. J.

ON THE BEACH AND THE BOARDWALK

Atlantic City is famous for its delightful climate, its invigorating salt-sea air, its surf bathing, its miles of Boardwalk and endless amusements—and CHALFONTE Hospitable, quiet, home-like.

*American Plan. Always Open*

THE LEEDS COMPANY



for curing suggests a possibility for the improvement of the manufacture of similar cheese in this country and the ultimate assembly of all the material at one central point for curing. Such an arrangement would minimize the expense and also would operate for the production of a superior quality product of uniform grade.

The Federal farming scientists in this country, for a number of years, have been experimenting with the potential purpose of perfecting the manufacture of a green mold cheese from cow's milk. For many years the attempts all resulted in failure and the experts ascertained that it was not sufficient merely to sprinkle green mold on the curd to produce Roquefort cheese. It was only with the greatest difficulty that the mold was made to develop properly; this process, at best, was very unreliable while available systems of refrigeration were not adequate, subsequently, for the proper curing of the dairy product. A low temperature was prerequisite, with plenty of ventilation and high humidity.

Finally, the Government dairying specialists devised a special air-conditioning apparatus which filled the bill to a T and which duplicated the natural conditions which obtained in the caves of Roquefort. As a result of this invention combined with the perfection of a process which permitted the substitution of cow's milk for goat's milk—as little of the latter material was available in this country—modern science has standardized Roquefort cheese manufacture and adapted it to our local conditions as efficiently as it solved the Swiss cheese riddle.

Before giving world-wide publicity to its new discoveries, the National Department of Agriculture produced both Swiss and Roquefort cheeses on a commercial scale for wholesale and retail trade at the Grove City, Pennsylvania, creamery, which is operated under the coöperative direction of Uncle Sam. During the last couple of years this cheese has been sold on the open market in active competition with the best grades of imported cheese with flattering results indicative of the superiority of the domestic product. In the case of the Roquefort cheese, some slight criticism has developed due to the fact that the color of the cheese made from cow's milk is yellower than that of the imported Roquefort made of goat's milk. This obtains from the fact that the fat of sheep milk naturally is whiter than that of cow's milk. However, it is anticipated that, as the domestic industry develops and more scientific attention is devoted to the study of cheese manufacture, additional perfection and improvements will result which will eliminate all existent sources of unfavorable comment.

## Safety for the Linemen

(*Continued from page 407*)

slightest pinhole or other defect that might admit of the passage of an electric discharge through the glove.

Each glove is filled with water to within about two inches of the top, being soused in the water for an equal distance from the top. Scientifically expressed, one terminal of a "step-up" transformer is then connected to the water inside the glove and the other to the water outside the glove. By the application of a regulating and measuring apparatus, not shown in the accompanying photograph, the voltage is raised to the specified value and maintained for five minutes, or until the glove "breaks down" or yields to the electric stress. The fact that occasionally several gloves in a single consignment cannot withstand the searching eye of the experiment emphasizes the value of periodic tests.

Rubber gloves purchased by Uncle Sam for use at the Panama Canal are tested by the Bureau of Standards before they can qualify for service. The stress is applied at 9,000 volts, a voltage higher than that required by active usage. Similarly, progressive electric power companies have

# Training For Service

What science and engineering have done to develop the mechanical efficiency of the telephone, specialized training has done in the development of workers.

Plant engineers, linemen, directory clerks, toll operators, equipment installers, electrolysis engineers, trouble hunters, line repairmen, test table operators, chief operators, contract agents, building engineers, line installers, exchange repairmen, plant inspectors, trouble operators, fundamental plan engineers, draftsmen, estimate clerks, exchange operators, cable testmen, equipment inspectors, wire chiefs, traffic engineers, galvanometer men, cable splicers, facilities engineers, surveyors, information operators, switchboard installers, accountants, testmen, supervisors, station repairmen, equipment engineers, directory operators, statisticians, appraisal engineers, routing operators and scores of other skilled employees are specially trained for the exacting work of providing telephone service.

Throughout all work of telephone construction and operation there is a ceaseless endeavor at mastery of service that makes for improvements beneficial to the public.

# Nine-Foot Saws Running 130 Miles an Hour

No one had ever built a saw nine feet in diameter. It took 80 years' experience and unlimited courage to do it. Men who were supposed to be saw experts said:

"You *can* make a saw as big as that, but the strain will be too great; no mandrel would hold, and 63 square feet of saw surface couldn't run straight and true at the tremendous speed demanded."

But two such saws were completed and installed in the Coats Shingle Mill at Hoquiam, Washington. Before a large gathering, many of them intensely skeptical, the saws made their initial run.

And they ran perfectly! The skeptics became enthusiasts as the gigantic saws—the biggest in the world—slashed through giant logs with a swift, clean cut.

It was the obvious thing for these saws to bear the Disston name, to be of Disston-Made Steel, and made by men whose lives and whose fathers' lives have been given to making Disston Saws.

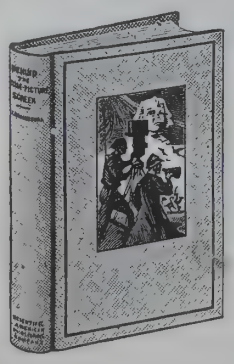
A New Book on a New Subject

## BEHIND THE MOTION-PICTURE SCREEN

*By* AUSTIN C. LESCARBOURA

HERE, at last, is the wonder book of the screen. It takes the reader into that marvelous land where films are made, and where the camera reigns supreme. Every step in the making of a photo-play is taken up in proper turn, from the planning and writing of the scenario to the projecting of the finished film on the screen in the picture.



Talking pictures, natural-color pictures, microscopic pictures and all phases of the motion picture are treated upon in due turn. This book is printed on the highest grade coated paper. It contains 428 pages and over 300 illustrations. Bound in an attractive cloth cover. Size 6¼ x 9¼. $3.50; postage—15c in the East, 20c to Chicago, 30c to the coast.

the rubber gloves used by their linemen tested when new and at specified intervals while subjected to service. Rubber deteriorates with age and use, and the life risk involved in outfits for workmen emphasizes periodic testing as an indispensable practice.

### Concerning Back Numbers

WE beg to advise our readers that all back numbers of the SCIENTIFIC AMERICAN within the current year, that is to say, 1920, can be furnished at a uniform price of 15 cents each, with the exception of our "Anniversary Number," which is 25 cents. All issues of the SCIENTIFIC AMERICAN back of 1920 can only be sent on receipt of 25 cents and only those numbers which are in print can be supplied. To avoid unnecessary bookkeeping, all orders should be accompanied by a remittance to cover the cost of the same. Back numbers of the SCIENTIFIC AMERICAN SUPPLEMENT for 1919 can still be supplied until January 1st, but earlier numbers as far as the supply goes can be purchased of the H. W. Wilson Company, University Avenue, New York City, to whom all inquiries regarding SUPPLEMENTS are referred. We are able to supply back numbers of the SCIENTIFIC AMERICAN MONTHLY, all issues for 1920 except August and September which were not published, for 50 cents each.

### Propping Fruit Trees with Staples and Wires

THE fruit tree with a fruit load much too heavy for its own trunk and limb structure isn't an unusual occurrence in either the small home orchard or the big commercial one. The common way of providing supports for such trees is to use wooden props, sawed out of scantlings. When wooden props first were used, lumber was cheap and easily obtained. This condition has radically changed, and the cost of props, used in any number, is a serious additional cost. Another drawback to props is that they require frequent attention. A storm comes, the wind blows hard—and props are down all through the orchard. When props are used, cultivation beneath the trees is interfered with.

Propping with staples and wires is a growing practice in California fruit districts. It is a method which requires some skill and judgment, but when properly done is economical and efficient. One wiring does for several years. The cost of the method is only a fraction of what propping with wood costs.

California expert orchardists find that the best time to prop is just before the fruit tree branches have become to bend under their load. In wiring, the endeavor is to attach wire to branches at the point where the center of the load will come. Two methods can be pursued. One is to have a central iron ring, within the tree, with wires running from it to the branches needing support. An advantage of this method is that if a wire breaks, only one branch is released.

For most trees, however, the more practical method is to run one wire around the branches requiring support, holding them in and together. Twelve or 13 gage wire is used. Fourteen gage is too light, while an objection to 12 gage is that, though very strong, it is hard to handle. So growers frequently compromise and use 11 gage. The wire is attached to the limb with a two-inch fence staple, except in the case of very small limbs, when a large picture screw-eye is used. Screw-eyes are used when a staple would split the wood.

In wiring, the endeavor should be to hold the tree in its natural position. If this is well done, the growing load of fruit will operate simply to strengthen the tree in its proper shape. If the [illegible] is not well wired, there is still [illegible]nger of damage from spreading when the full load begins to be felt.—By *J. T. Bartlett.*

## "All Right, Then—I'll Go To Hell!"

"It was awful thoughts and awful words, but they were said and I let them stay said."

It had felt good to be all washed clean of sin and to be able to pray—but Huck couldn't tell Old Jim no matter how sure it would make him of going to Heaven.

So he tore up the note and swore he would never reform again. He would steal Jim out of slavery, he would—and if he could think up anything worse, he'd do that too. As long as he was going to hell anyway, he might as well make it worth while. Who ever knew the heart of a boy as does

# MARK TWAIN

*12 Vols. At a Low Price*

## FREE—Rex Beach

*5 Volumes*

Rex Beach is the most popular writer of thrilling stories living today. He is the man who knows, as no other, the big outdoors, that is the Klondike.

Plenty of humor—plenty of scrapping—big, raw-boned men who can whip their weight in wildcats—the women these men fight for and die for—all these you will find in Rex Beach's vivid, human novels.

## Only a Few Sets FREE

Rex Beach now costs you $2.00 for each volume in the book store. But we have made a small special edition and so as long as this small special edition lasts you can have 5 volumes—about $10 worth of books—**absolutely free.**

Rex Beach has sacrificed much of his royalty so that we can do this on one edition.

If you are prompt you can get your set free. If you are too late we will return the coupon—but don't wait.

Send the coupon for both sets for examination. Send no money—just the coupon. Send it at once.

HARPER & BROTHERS
*Est. 1817* New York

**HARPER & BROTHERS, 21 Franklin Square, NEW YORK**

Send me, all charges prepaid a set of Mark Twain in 12 volumes, illustrated, bound in handsome green cloth, stamped in gold, and Rex Beach in 5 volumes, bound in red cloth, free. If not satisfied, I will return them at your expense, otherwise I will send you $1.50 within 5 days and $2.00 a month for 14 months.

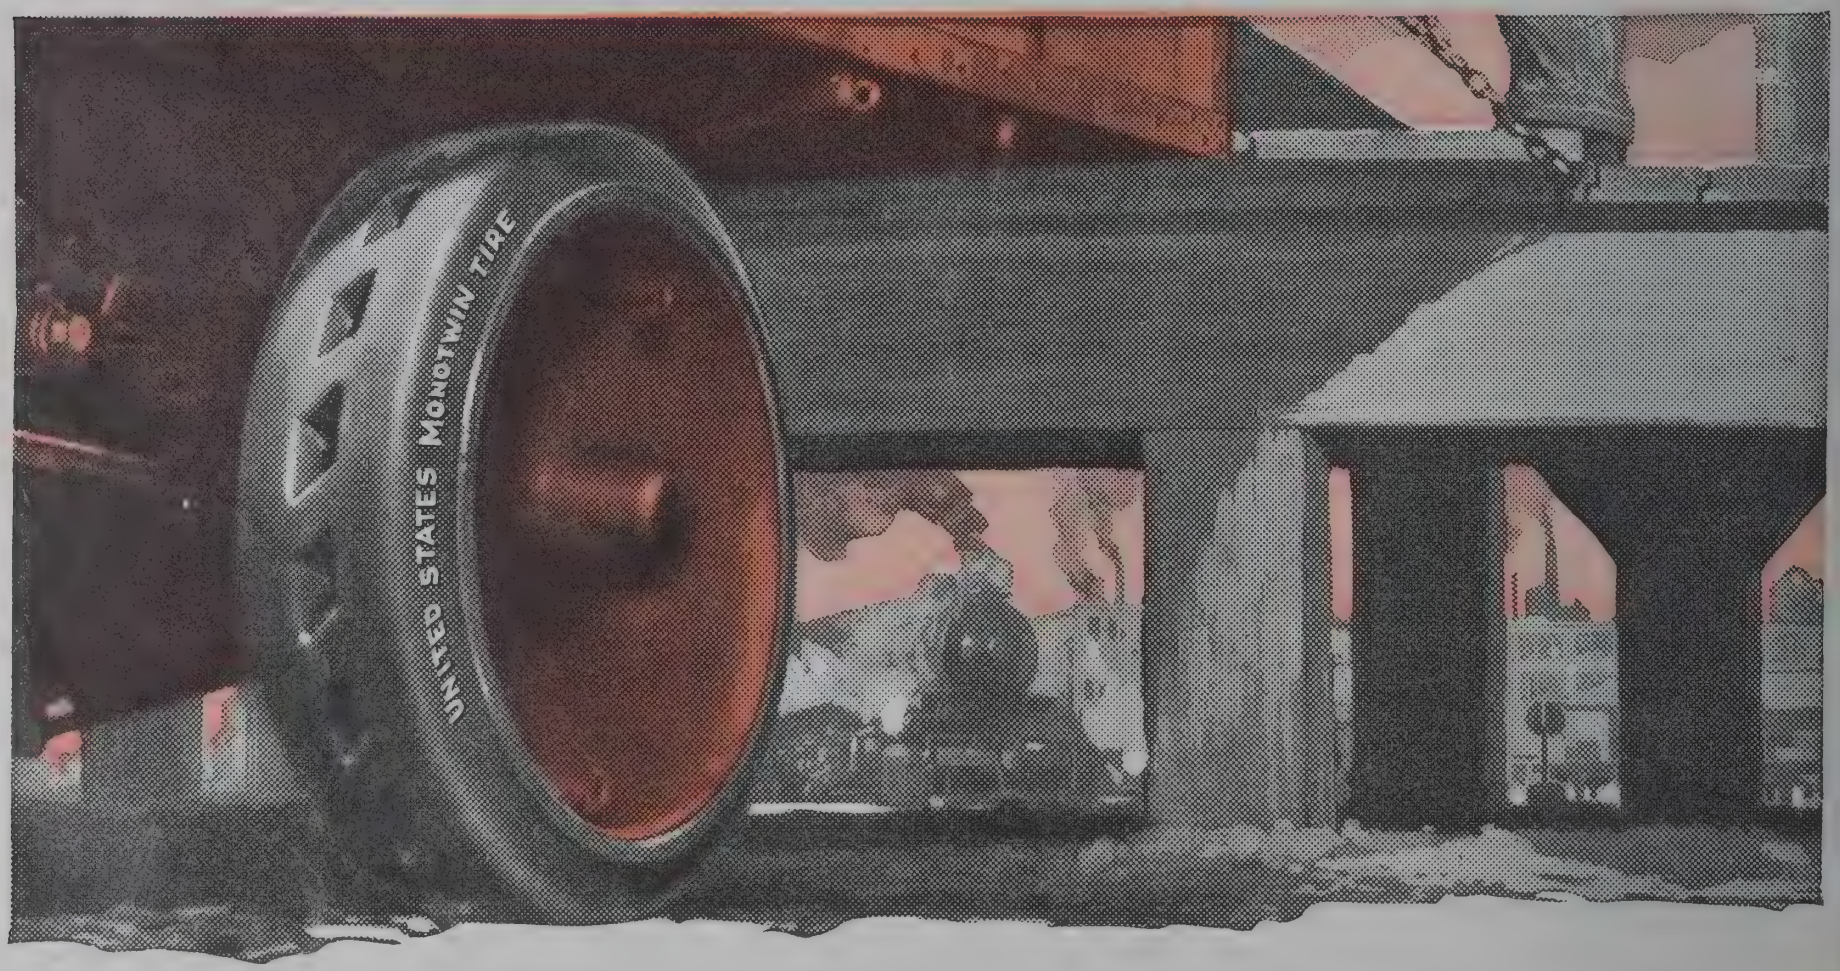
# The Fastest Selling Solid Truck Tire in America — the MONO-TWIN



TALK to the truck owners of this country about *economy*—even an economy that may not be immediately apparent—and you will always find them ready and willing to listen to you.

When the United States Rubber Company announced the creation of its new Mono-Twin Solid Truck Tire, two months ago, it expected that truck owners would be interested.

What it didn't foresee was how quickly and almost universally they would appreciate the *results* towards which this company had been working.

* * *

Two months is a short time in which to have the results of years of scientific endeavor meet with such general and enthusiastic acceptance.

But truck owners all over the country have learned their lesson. They have followed the unsound and the unscientific to their logical conclusions.

They know now which way economy lies. And they are more than ever out to find it.

* * *

For those who overlooked the first announcement regarding the Mono-Twin, we reprint these few facts bearing on its economy:

It is built of *grainless* rubber—an exclusive U. S. creation—*non-splitting.*

*Chemically* joined to its base—ending base separation.

Its combination of rubber cross-bars and depressions *increase traction*—*dissipate traction heat*—act as a *non-skid* tread—enable the tread to *wear down uniformly* with no necessity for regrooving.

It carries a *heavier load* than two single tires of half the section width—adding to its *cushioning qualities,* reducing the wear on truck and driver.

Any U. S. Solid Truck Tire representative will be glad to give you further information.

Talk to him. He is a truck *tire expert.*

*And specify the U. S. Mono-Twin when ordering your new truck.*

## YOUR GASOLINE BILLS

Gasoline is high. It may go higher.

The public demand is greater economy.

Economy, in a motor car, is measured by the extent to which *useless weight* is eliminated.

Whether little or big, a motor car is a *product of steel.*

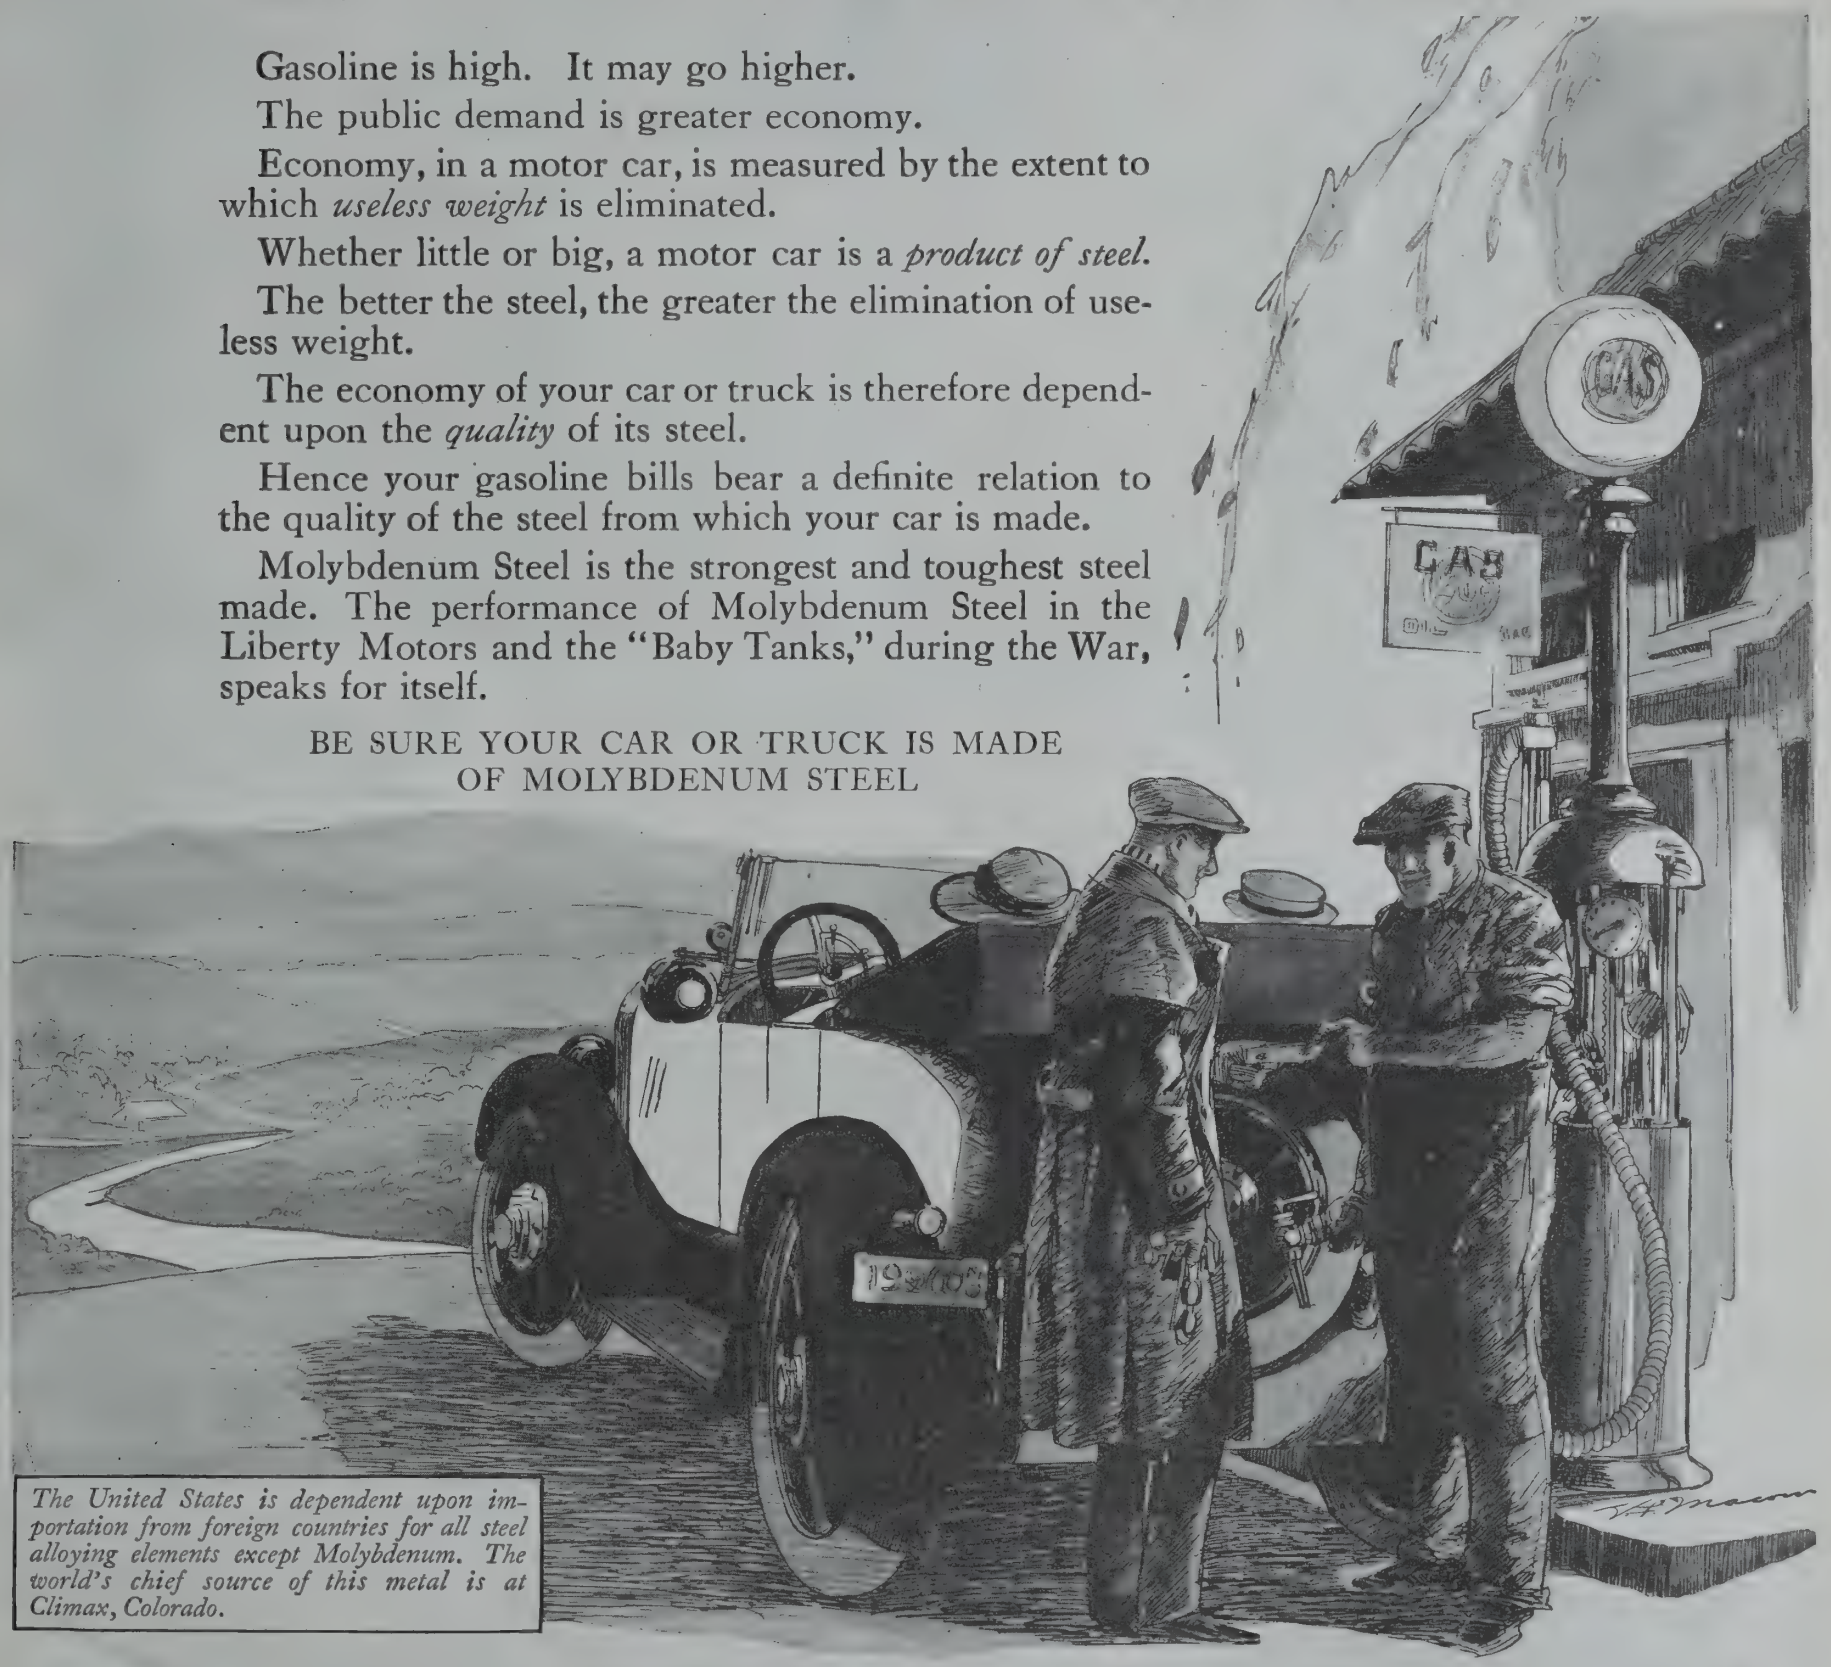
The better the steel, the greater the elimination of useless weight.

The economy of your car or truck is therefore dependent upon the *quality* of its steel.

Hence your gasoline bills bear a definite relation to the quality of the steel from which your car is made.

Molybdenum Steel is the strongest and toughest steel made. The performance of Molybdenum Steel in the Liberty Motors and the "Baby Tanks," during the War, speaks for itself.

BE SURE YOUR CAR OR TRUCK IS MADE OF MOLYBDENUM STEEL



*The United States is dependent upon importation from foreign countries for all steel alloying elements except Molybdenum. The world's chief source of this metal is at Climax, Colorado.*

**Climax Molybdenum Co.** *associated with* **The American Metal Co., Ltd.**

*61 Broadway —— New York*

*Climax Molybdenum Company is the largest producer of Molybdenum in the World.*

# For every requirement

"My Mack trucks, loaded to the top, frequently come up the Montgomery Street Hill – a grade of about 25 per cent. I am now figuring on a contract that will require ten more 7½-ton Macks, which will bring my total fleet up to twenty."—*From one letter of hundreds we should like you to read.*

THE Mack motor has sufficient reserve power for work far in excess of normal requirements. In the 3½ to 7½-ton models, the bore is 5" and the stroke is 6". While rated at 40 H. P., it has developed 74 H. P. on 100-hour continuous brake tests. It has a three-point suspension and is easily demounted.

Distinctive Mack engineering features, combined with 18 basic Mack patents, have developed the motor truck the world is talking about.

*Capacities 1½ to 7½ tons. Tractors to 15 tons*

Our latest catalogues, Nos. 13 and 39, contain a detailed description of the many exclusive features that have made Mack supremacy possible, together with the complete specifications of every model. Send for them today.

**The compact household which packs into a trunk or case yet which has all the comforts of the modern home**

## The Household That Packs into a Trunk

CONDENSED households seem to be the order of the day. A few years ago the world was accustomed to spacious homes in city and country alike. But with the housing shortage there has come a sharp retrenchment in household space, and ingenious architects are busily engaged in planning small and still smaller rooms in both new and old houses, while clever and enterprising inventors are developing convertible and nesting furniture which can be used to the best advantage in the small space now available.

The old scheme of one room for one purpose—the dining room, sitting room, bedroom, and so on—is fast going out of date. There is afoot a very definite tendency to make every room serve for several different purposes. Thus we find the living room replacing the parlor or sitting room, and this same living room not only serves throughout the day but is also provided with a davenport or other form of bed for use at night. At least one company engaged in manufacturing ready-cut houses is now featuring small houses in which every room, by means of closets and other devices, can be used for a variety of purposes. This is truly condensed housekeeping, is it not?

Now comes a young French inventor, M. Louvet, with an entire household which, when completely packed, measures 49 by 54 by 33 inches, thus permitting it to be packed in the large trunk or to pass through any door without difficulty of any kind. Yet the five pieces of furniture contained in the case cover a floor space of 78 by 103 inches when spread out. In these pieces are contained all the other combinations and accessories for the household.

An inventory of the Louvet compact households reveals the following items: A bed for two persons; metal bed spring, mattress and necessary sheets and other bedding; a child's cot, with springs and bedding; a table 49 by 30 inches; a side board with dishes for three persons; a pedal-operated sewing machine; a linen closet containing all the linens necessary for the household and a child; a chaise longe; two chairs for adults; a child's chair; a folding stool for adult and another one for a child; a children's bench; a piece of furniture serving as desk and dressing table; a revolving stool with a shaving glass attached; a lady's mirror; a lady's sewing table with all accessories; a carpenter's and metal worker's tool box; a stove for heating; a clothes-washing outfit with large tub that can hold as much as 130 quarts of water; and all accessories for a home such as lamp, pictures, clothes hangers, etc.

The table, which is shown in three of the accompanying illustrations, contains all the kitchen accessories. There is also a sewing machine which folds up on one side of the table, as shown. There are several drawers for odds and ends. Each object has its special place in a compact form, so that nothing rattles or falls out.

With two of the chairs a chaise longe is easily made. All the chairs contain compartments which hold all the necessaries for a bedroom. The double bed at the bottom has drawers and cupboards containing other accessories.

## Changes Rule of Road

THE automobile brought with it in British Columbia an agitation to change the rule of the road, and spasmodically in this Canadian province for a dozen years there have been organized efforts to bring about the change. Along with Prince Edward Island, British Columbia has always "turned to the left," after the English fashion, since the days of first settlement. The rest of Canada followed the American rule of the road, which is also the Continental.

The British Columbia government decided at the last session of the Legislature to adopt the American rule, and the change will soon be put into effect.

Chief opposition to the change was from the electric railways, who claimed that heavy expense in altering equipment would be unavoidable. There were also the usual arguments that the "natural" way to turn is the left. Turning either to the right or to the left, experience shows, is largely a matter of habit, quite easily acquired, and with the advent of the automobile the most cogent argument for turning to the left—namely, that it enables the driver, sitting on the right, to watch the wheels in passing—has lost great caste. This objection to the right-hand drive caused automobile manufacturers to change to the left-hand drive, and the objection no longer existed.

In any event, British Columbia decided that it would be fairly simple for its population to "learn over" a rule of the road, to break itself of the old habit and form a new one. Surrounded by peoples using the American system, and with the automobile and automobilists from outside always urging standardization, British Columbia decided the practical move was to change the rule.

Historians say that charioteers in Roman arenas turned to the left, and that the legions of Severus, marching through Britain, kept to the left.

## New Use for a Rare Element

NEW uses for rare metals or elements seem to be appearing constantly. The metal selenium is not a familiar one but is a by-product in the electrolytic refining of copper. Demand for it has been very light and its chief use has been in the glass industry, in photographic chemistry and in medicine. It has also been used to a limited extent in electrical work, because it possesses the peculiar property of varying conductivity according to the intensity of the light. Under the influence of light its conductivity may be 500 times greater than in the dark. As the result of research work carried out at the University of Wisconsin by Prof. Victor Lenher, a new property has been discovered which should open up a big field for the application of selenium and incidentally make it worth while for copper refiners to pay more attention to its recovery. In the form of selenium oxychloride it acts as a powerful solvent on certain organic substances. The unsaturated hydrocarbons, such as acetylene, benzene, and toluene, dissolve readily, while the paraffin hydrocarbons, such as gasoline, vaseline, and paraffin wax, are unaffected. Pure rubber, vulcanized rubber, asphalt, bitumen, and the casein glue used in airplane construction dissolve easily in selenium oxychloride, and it can be used in coal analysis to extract the bituminous material in soft coals.

## Freight Handling and the High Cost of Living

IN view of the number and diversity of the causes which are given for the present high cost of living, it may well be that the only fact of which the average citizen is absolutely sure is that the cost is high. As a matter of fact, present conditions result from a multiplicity of causes, some near at hand and readily recognized; others, so far as public observation goes, being more remote and liable to be entirely overlooked. Among these may be classed that part of the high cost of living which is chargeable to out-of-date and inefficient methods for the handling of freight at railroad and steamship terminals.

It is an amazing fact that in the land which is preëminent for the manufacture of labor-saving machinery, we should be making less use of such machinery in the matter of freight handling than some of the leading countries of Europe. How this condition has been brought about it would be interesting to discover, but probably we shall not be far from the truth if we say that it is traceable to that pronounced spirit of conservatism which in this matter of freight handling, as distinct from freight hauling, has dominated our transportation interests both on land and sea. This, however, is an explanation which does not explain; for in the hauling of freight, once they have got it on the cars, our railroads have shown a characteristic American ability to cut down costs by continually enlarging and improving their locomotives and cars; so much so that, today, we are hauling freight at a cost that is far below that of any country of the world.

Why is it that in the bringing of raw materials to our factories, in working these materials up into finished products and in hauling them from the factory to the consumer, we have developed handling machinery famous the world over, and yet have failed to make any commensurate use of such machinery in the handling of package freight at terminals and transfer points, both on our railways and at our great seaboard terminals?

How greatly the high cost of living is affected by failure to make full use of labor-saving appliances in the handling of mixed and package freight is shown by a comparison of the costs of hauling freight once it is upon the cars with the cost of handling it at the point of destination. Thus, we are told by Harwood Frost, writing in *Marine Engineering*, that the average expense of hauling a ton of freight 240 miles is 74 cents, while the average expense of handling the same ton of freight at the terminals is 75 cents, and he quotes as an example the case of the short haul between Philadelphia and New York, where the cost of handling at the terminals is $3.65, whereas the railroad cost for the 90-mile haul is only 27 cents. We are told that it costs less for the 1,300-mile marine haul from Havana to Boston than it does to transfer the same freight from one pier in Boston Harbor to another. Similarly, it costs more to transfer a barrel of flour from the car to the hold of a ship in New York than it does to carry it by that ship from New York to Liverpool.

The country is now engaged in one of the greatest commercial enterprises in its history, upon which it has already expended considerably over three billion dollars. We refer to the activities of the Shipping Board and the great fleet of over six million gross tons which the Board now has in its care. With this equipment we are endeavoring to win our proper share of the deep-sea-carrying trade of the world. In this effort we shall have to match our wits against the nations which, through long years of experience, have become thoroughly efficient in the building and routing of ships and who have established on a comprehensive scale all the complicated machinery which is necessary for the gathering and distribution of world-wide trade. We are handicapped by the fact that we have to build our commercial structure from the ground up, and we are under the severe handicap imposed by the obligations and restrictions of the Seamen's Bill.

Our crews are better paid, better housed, and by law we are obligated to carry a larger number of men than our competitors carry on a ship of the same tonnage. The only direction in which we can look to overcome the handicap against us is in the reduction of the turn-around by shortening the time which shipping must spend in our ports, and the most effective way and the only way in which this can be done is by utilizing to the utmost limit the various labor-saving devices such as electrical cranes, hoists, conveyors, tiering machinery and other handling devices that are used so extensively by our foreign competitors.

We understand that the Railroad Committee of the Chamber of Commerce of the United States has been making a study of this most vital question, and that constructive recommendations will shortly be made relating to the question of freight handling at terminals. Necessarily this will include both railroad and marine transportation. The report should be most widely distributed and a campaign of education undertaken with a view to getting the constituents both inland and on the seaboard to urge upon their Congressmen the need for taking hold of this vital question at once and with a liberal hand.

## Motor Trucks and Country Bridges

IN view of the rapid increase in motor truck service in rural districts it is high time that the authorities looked into the question of the strength of the smaller country bridges and their ability to stand up under the increasing stresses to which they are being subjected by the weight and speed of motor truck traffic.

The benefits which have been conferred upon outlying farming communities by the rapid spread of the new system of freight transportation are so apparent, that it is certain, not only that rural motor truck service has come to stay but that it will be enormously extended. Not only will the total freight carried grow rapidly, but there will be an inevitable increase in the size and speed of the individual trucks.

The art of road building has progressed to the point at which we can construct roadbeds that will stand up under the most exacting service; but we question whether the bridge builder has kept pace with the road builder. It is certain that a careful survey of country bridges, made by competent bridge engineers, would discover hundreds of structures that are being stressed beyond the limits of safe and conservative practice.

In this connection we wish to draw attention to a most important element in bridge design, which only of late years has begun to receive the attention which its importance demands. We refer to the question of impact. It is only now beginning to be realized that, even in steel bridges of the first magnitude, the difference between the stresses due to static as against dynamic effect may be enormous. A train moving very slowly across a bridge is one thing—the same train rushing across the structure at from forty to sixty miles an hour is quite another, and the increase of the stresses due to the hammer blow of the flying mass, may concievably be from fifty to one hundred per cent.

The difficulty of making an exact determination of the dynamical effects of impact on the members of bridge structures is due, in part, to the want of suitable appliances. Laboratory tests on small-scale structures would teach us something; but we doubt if the data thus secured would be accepted by engineers as a sufficiently reliable indication of the actual impact stresses in the full-size bridge. The successful results of the investigation by Mr. Fowler of the Niagara Bridge suggest that the impact problem may be solved along similar lines. There is considerable divergence of opinion among bridge engineers; but it is probable that impact stresses increase as the square of the velocity of the moving vehicle.

Undoubtedly the effects of impact are felt most severely by the floor system, and proof of this is seen in the fact that, in the cases where country bridges have given way, it has generally been the floor system (floor beams, stringers or planking) that has failed. Instances of the complete collapse of the trusses are comparatively rare.

A survey of the highway bridges of the country would show that, although the trusses are generally sufficient for their work, many of the floor systems should be rebuilt. And in connection with this matter of impact, we wish to emphasize the importance of maintaining a true surface on the planking. To replace a worn down plank with one of the original thickness results in a heavy impact on the bridge, when a five-ton truck, running at twenty miles an hour strikes the obstruction—for such it is. The new plank or planks, as the case may be, should be adzed down to match the general surface.

We commend this subject of impact on highway bridges to the attention of road commissioners as one which calls for immediate action. Fast freight motor traffic, we repeat, has come to stay; our highways are equal to the new conditions, but too many of our highway bridges are not. They can be made so by a partial rebuilding at a cost that would not be excessive.

## The Hudson Vehicular Tunnel

A RED letter day in the history of urban transportation was October 12th of this year, when Governor Edwards of New Jersey and Lieutenant Governor Walker of New York broke ground at the New York end, thereby inaugurating the construction of the vehicular tunnel beneath the Hudson River, the first great tunnel of its kind to be constructed in the new world. Tunnels of this character have been built before, notably the Rotherhithe Tunnel, London, and one beneath the Elbe at Hamburg. But these two, because of their shorter length, are not burdened with the great problem of artificial ventilation, which renders the construction of the Hudson River tunnel so formidable an undertaking.

The twin-tube structure will measure nearly one and one-third miles between end portals, and the outer diameter of each tube will be 29 feet. The Rotherhithe Tunnel has a span of 1,570 feet between the ventilating shafts, whereas there will be a stretch of 3,800 feet beneath the tide and between the off-shore ventilating shafts. Of these last-named there will be four, two near the pierhead lines and two inshore, near the tunnel entrances and exits. A cross section of the tubes shows that they will be divided horizontally by two partitions, the upper chamber being used for the outflow of the foul air, the lower chamber for the inflow of fresh air, and the middle chamber being devoted to traffic. The roadbed will be 20 feet wide, with a clearance of 13 feet 6 inches between the floor level and the under side of the ceiling.

To ventilate the tubes there will be provided 65 electrically-driven fans which will be sufficient to effect a complete change of the air 32 times every hour. The operation of the ventilating system at maximum capacity will call for the annual expenditure of $280,000. The traffic is estimated for the first year at 119,000 horse-drawn vehicles and 2,686 motor vehicles, and in the tenth year, the figures show a potential one-tube traffic of 68,000 horse-drawn as against 5,916,000 motor vehicles. Twenty years from the opening of the tunnel, it is estimated that the dual route should be handling a total of 15,800,000 motor vehicles in the twelvemonth.

The cost of the tunnel is now put down at $28,669,000, which will be equally divided between the two States. It is expected that, in eleven years, the operating revenue will have yielded sufficient income to amortize the cost of the tubes, and that at the end of twenty years each State will have to its credit a surplus of $33,635,000, or sufficient to build another double-tube tunnel. In three and a half years the tubes should be open, and the intolerable congestion and delay of the present ferry service will, mercifully, become a thing of the past.

## Electricity

**A Plug Bushing Which Grips the Cord.** — For taking the strain off the binding screws of plugs a new bushing has been developed by an electrical manufacturer. The hole in the bushing has a number of inwardly projecting bosses which serve securely to grip the outer surface of the wire around its entire circumference. Thus the strain on the wire is taken by the bushing and not by the binding screws. The threading is standard ⅜-inch iron pipe size. It is therefore possible to attach the cap to socket handles, etc.

**A Self-Cleaning Lighting Fixture.** — An electric fixture which cleans itself every time the light is switched on or off has been placed on the market. The fixture consists of a reflector, a pull switch, a cord, and a cleaning device comprising two wiping blades. Every time the cord is pulled to operate the switch it simultaneously brings the two wiping blades into action. Each blade makes a complete revolution, one against the reflecting surface of the reflector and the other against the lamp bulb. In this way the dirt is swept off both lamp and reflector.

**Combination Fan and Heater.**—There is nothing new in the idea of using an electric fan for the purpose of distributing heat about a room, but no one had attempted to combine the electric fan and the electric heater until the advent of the recent device. This device is a standard fan, to the guard of which is attached a nichrome heater. The fan and the heater have independent connections, attaching to any socket, and combined, in the domestic size, require 600 watts. The fan-heater is made in larger sizes for industrial purposes. In summer time the fan alone is operated, so as to serve for cooling purposes.

**Briquetted Plates for Storage Batteries.**—A new type of storage battery is described in a recent issue of *Science Abstracts*. This new battery, which is of Swedish origin, appears to be a modification of the nickel-iron alkaline cell as made by Junger, the chief characteristic being the method of making up the plates from briquettes of active material, which are automatically fed in between two perforated nickel-steel strips. These strips inclosing the active material are manufactured in lengths folded together and fitted into a steel frame. The complete electrode is then put through a rolling process to ensure perfect contact between the active material and the strips.

**Radio Telephone for Seaplanes.**—It is reported that the U. S. Navy is now making use of radio telephone sets for seaplanes with which a transmission radius of over 150 miles has been obtained. The transmitter radiates at two wave lengths, 1,600 and 600 meters. For the former wave length a trailing wire antenna of 0.0004 mfd. is employed, for the latter an emergency aerial of 0.00026 mfd. The transmitter is supplied with two three-electrode tubes of the pliotron type. One tube is employed as an oscillator for the production of radio-frequency currents and the other tube is employed as a modulator and as an amplifier of the voice currents that are communicated to it by the microphone.

**Coolidge's X-Ray Tube.**—A summary of a lecture delivered by Dr. W. D. Coolidge before the Röntgen Society in England appears in a recent issue of the London *Electrician*. It was said that progress in the development of the X-ray tube was possible only when the art of manufacturing and working tungsten had been mastered. Dr. Coolidge dwelt in considerable detail on the present method of purifying and reducing wolframite and the operations of sintering the powdered tungsten metal into blocks and plates from which disks could be prepared, when white hot, suitable for the targets of X-ray tubes. The essential requirements of a target in an X-ray tube were stated as follows: (1) A high melting point to permit sharp focusing of the cathode rays without fusing the target. (2) A high atomic number to secure a large yield of X-rays. (3) A high thermal conductivity to enable the heat to be got rid of. (4) A high heat capacity to withstand intense momentary discharges as in diagnostic work. (5) A low vapor pressure to prevent the metal being deposited on the walls of the bulb.

## Astronomy

**Masses of the Nebulæ.**—One interesting corollary of the epoch-making studies of nebulæ recently carried out at Lick Observatory, and reported in Vol. XIII of its publications, is that the rotational velocities of several bright-line nebulæ, as determined with the spectroscope, serve, with certain assumptions, to indicate the masses of these bodies. In three cases the masses indicated are 162, 3.7 and 18.8 times that of the sun. The planetary nebulæ in which rotational effects have been observed appear to be at least several times as massive as the sun, but the fainter and apparently smaller planetaries are probably less massive, in some cases, than the solar system.

**The Subterranean Clock Room** of the Argentine National Observatory is described by M. L. Zimmer in the *Astronomical Journal*. This room is interesting for the reason that it maintains a constant temperature without any auxiliary apparatus. A hole 10½ meters deep and 2 meters in diameter was sunk and the room was constructed of re-enforced concrete, treated with a water-proof mixture. The Riefler clock in the observing room is synchronized with one of the two standard clocks underground, so that there is never any necessity for descending into the lower room. Surface vibrations have little or no effect upon the room, but earthquake shocks would stop the clock, and there appears to be no remedy for this difficulty.

**Interchange of Wireless Time Signals.**—A large part of the May, 1920, number of the *Monthly Notices* of the Royal Astronomical Society (published in July) is devoted to articles on a subject now very prominent in astronomical circles; viz., the exchange of wireless time signals by the great observatories of the world. Some of the objects to be attained by concerted work in this line are thus set forth by Professor Sampson: (1) A more exact knowledge of longitudes, implying the final settlement of the most obstinate of geodetical problems. (2) Consistency in time determination throughout the world. (3) Elimination of small remaining errors in systematic right ascensions of stars. (4) Improvement in the knowledge of clocks as timekeepers and as chronographic instruments. (5) Some reaction to the benefit of radio research. Great progress has already been made in apparatus for obtaining autographic registration at the observatories of time signals from high-power radio stations in remote parts of the world. Thus Greenwich Observatory now regularly records the signals from Paris, Nauen, Lyons and Annapolis, and occasionally those from Darien. Efforts have been made, without success as yet, to detect at Greenwich the signals from San Diego, Cal., and Honolulu. An international program will probably be adopted at a meeting of the Commission de l'Heure in 1922.

**The Total Solar Eclipse of September 20, 1922.**— Plans are being made to utilize this forthcoming eclipse for a further test of the Einstein hypothesis, for which purpose it will be more suitable than the eclipse of 1923. The field of stars in which the sun will be located at the time of the eclipse has recently been photographed with an astrographic telescope stopped down to 7 inches aperture, using rapid plates, and a diagram of the field is published by the British astronomer royal in the *Monthly Notices* for May, 1920. Information concerning possible stations for observing the eclipse has been communicated to the Royal Astronomical Society by Mr. A. R. Hinks. There are three convenient locations: (1) Bandidu, in the Maldive Islands, is on the central line, with a duration of 4 minutes 10 seconds and an altitude of 34 deg., at which good photographs may be obtained. It has the advantage of occurring at 8:10 a. m., local time, before the temperature has risen; there will consequently be little or no fall in temperature during the eclipse. (2) Christmas Island, in the Indian Ocean, although some distance from the central line, has a duration of 3 minutes 42 seconds, with an altitude of 78 deg. The eclipse occurs here at noon. (3) The western coast of Australia is impossible, on account of lack of communications, but eastern Australia is favorable. Cunnamulla, in the interior, is accessible by railway. With a duration of 3 minutes 45 seconds and an altitude of 26 deg. good work might be done here.

## Automobile

**Fit Piston Rings to Cylinders.**—The practice in many repair shops is to fit the rings to the pistons, but not to the walls of the cylinders, with the result that space is left between the ring and the cylinder wall through which the compression leaks. The object of fitting rings in this manner is to save time and trust to luck that the rings through wear will eventually conform to the walls of the cylinder. A ring that is fitted correctly conforms to the cylinder wall as soon as it is put in. Such a ring should be lapped in with fine carborundum and oil, grinding it to a fit with the cylinder wall of the cylinder in which it is to be used.

**A New Type of Windshield Cleaner** recently put on the market is a chemically treated cloth which is wiped over the glass, after the latter has got wet. The result is to break up completely the tendency of the water to stand in drops on the glass or run over it in streams, and since it is this formation that impairs vision, the cloth is decidedly effective. The water, after application of the cloth, stands in a uniform thin and altogether transparent film over the surface of the glass—a film so thin that there is no appreciable refraction and vision through it is excellent. The manufacturer states that one application of the cloth is enough for 24 hours of wet weather, but this statement we have had no opportunity to check up.

**Clear Out Cooling System in the Spring.**—To give a thorough cleansing to the cooling system, disconnect the short section of hose between bottom of the radiator and pump, connect the garage hose to the water pump and a longer section of hose to the bottom pipe of the radiator and lead it outside of the truck. Plug the overflow tube with a cork or rubber stopper. Turn on the water after starting the engine and it should be pumped through the water jacket and radiation till it runs clear. If the radiator and water jacket of the engine are found to contain considerable scale or rust, it may be necessary to flush the system out with a solution of hot water and washing soda and it may even be desirable to allow the washing soda solution to remain in the water system over night to make sure the scale is loosened.

**Trucks Save Farms from Flood.**—The value of a motor truck in an emergency was never better illustrated than on April 26, when floods threatened to destroy the levee protecting the Spring Lake farming district. It was necessary to secure 25,000 cement sacks to be filled with sand and earth to protect the crumbling embankment. These sacks were located in various sections of Central Illinois and a fleet of motor trucks was utilized for the purpose of collecting them. One of these owned in, and starting from, Bloomington, made the run with 3,000 sacks, weighing 2 tons, from Bloomington to Manito, 60 miles in 3 hours and 10 minutes, moving over poor roads, rough in many places and interspersed with mud holes. This performance demonstrates that with decent highways and motor truck equipment the United States could be made immune from serious effect upon business due to railroad strikes and greatly increase its ability for defense in event of a foreign invasion.

**Small Fields Are Expensive.** — On a number of Missouri farms that have been keeping complete cost account records, in coöperation with the University of Missouri College of Agriculture, an average of the labor required for different size fields of corn shows that the 35-acre fields average 46.6 per cent more economical of man labor and 31.4 per cent more economical of horse labor than the smallest fields of three acres each. The average amount of labor required per acre for the different size fields was:

| Average size of fields | Yield in bushels | Man hours | Horse hours |
|---|---|---|---|
| 3 Acres | 32 | 31 | 51 |
| 8½ Acres | 30 | 25 | 45 |
| 12 Acres | 30 | 25 | 43 |
| 18 Acres | 33 | 23 | 39 |
| 23 Acres | 29 | 16 | 33 |
| 34 Acres | 26 | 17 | 35 |

These figures are for average size horse-drawn machinery. The tractor capable of drawing the larger horse-drawn machinery would emphasize still more the economy of the larger fields.

# Making the Hetch-Hetchy Dam Itself

## How California's Big Water Development Is Carried On with Its Own Water

By J. F. Springer

LARGE engineering works often involve subsidiary constructions of considerable size whose primary function is merely to promote the main operations. Thus, in the great Hetch-Hetchy enterprise, which is ultimately to supply San Francisco with 400,000,000 gallons of water per day or whatever part of this immense amount will be needed, it has become advisable not only to build motor truck roads but to construct a standard gage railroad 68 miles long. Another large subsidiary undertaking is the power station which is to supply electric energy for the operation of power-driven appliances which are to be engaged upon the construction of the great Hetch-Hetchy Dam, one of the main features of the whole enterprise, and of an 18-mile tunnel of the main aqueduct.

The power development is for construction purposes—at least primarily. The water for it comes from the beautiful Lake Eleanor whose outlet has been dammed by a multiple arch dam and whose area and impounding capacity have been thus increased. Lake Eleanor is at a considerably higher elevation than the power house and the difference in level is by no means all used in providing the hydrostatic head back of the pressure water entering the turbines. The bed of the Eleanor Creek at the site of the dam is 2,347 feet higher up in the mountains than is the power station. The water rushes down Eleanor Creek and into the Cherry River. At a point on this stream some 3½ miles from the power house, a dam has been constructed whose function it is to divert sufficient water from Cherry River to operate the turbines. This diversion dam diverts the water into a channel or conduit. From this the water flows into a steel penstock which runs down a steep incline. The capacity of the canal is 200 second-feet. This part of the construction is by no means uniform. One mile is of canal lined with concrete; one mile of the total is devoted to five tunnels; and 1½ miles in all to three flumes. While the canal is lined, the tunnels are not, except at portals and a few scattering locations. The construction of the tunnels has proven pretty hard work, as the rock formation is of granite. However, rock spoil derived from the tunnels was found useful as coarse aggregate for concrete work. The flumes were constructed of wood. The minimum section is 5 x 6½ feet. Ultimately, this temporary construction is to be replaced by rock tunnels. The concreted canal and Lake Eleanor Dam are to be retained as permanent parts of the general work.

The power house is 12 miles distant from the site of Hetch-Hetchy Dam. Naturally, this dam is the means of impounding the water of Hetch-Hetchy Reservoir. This dam and reservoir are also, like Eleanor Dam and Lake, farther up in the mountains than the power development under consideration. The great dam is, however, at an elevation considerably lower than the smaller one. Hetch-Hetchy Reservoir will discharge its waste into the Tuolumne River. The water for San Francisco will, however, be delivered to a tunnel which will, for a considerable distance, carry the supply down along a line roughly parallel to the Tuolumne River on one side and the Hetch-Hetchy Railroad on the other. This tunnel will be 12 miles in length and will deliver its water to a great power house. After passing through this station, the water will enter a long stretch of tunnel. Whenever the water from Lake Eleanor is to be sent on to San Francisco, it will naturally be passed into this long tunnel as well as that from Hetch-Hetchy Reservoir. This tunnel will be 18 miles long and will extend from Early Intake, near both the power houses already mentioned, to Priest Regulating Reservoir. The Cherry River power station supplies current for construction purposes on this great tunnel. There are two large pieces of work which this power house is to care for, one being the tunnel and the other the great dam. Its location is well adapted to serve both. The most distant point of the tunnel will be at its lower end some 18 miles away in the direction of San Francisco. The big dam is 12 miles distant in the opposite direction.

The tunnel to Priest may be divided into two sections. The one nearer Early Intake is perhaps 6 miles long and has a great mass of rock overhead. The other section is some 12 miles long and is farther down the line. It is also covered with a great mass of rock. The point of junction, however, where the one terminates and the other begins is in the bottom of a big ravine where the south fork of the Tuolumne River cuts across the line of the aqueduct. The entire 18 miles of tunnel may be viewed as a single section of downgrade of unvarying inclination. The tunnel diameter is 10¼ feet and the difference in level between terminal portals is 150 feet. The capacity of this tunnel is necessarily, at least equal in amount to the contemplated delivery at San Francisco. There are in all four portals, two being intermediate. The Hetch-Hetchy Railroad touches practically all of them. This is important in the matter of prosecuting construction.

The portal at Early Intake is far below the level of the railroad; so that all the material delivered here has to be lowered. This is accomplished by means of an inclined tramway 3,800 feet long. An electric hoist is located at the upper terminus and supplies the power for operation. The steepness of parts of the incline may be judged by the fact that the grades run up to 78°. There is also another tramway at the portal 18 miles farther down the line at Priest. This is a counterbalanced affair and is used to lower supplies from the railroad. Construction plants have been set up at the termini, at the crossing of South Fork and at two shafts in intermediate locations. Standard mining equipment has been given the preference when providing these plants, one object being to reduce the cost of repairs and the amount of spare parts that would need to be carried in stock. Among the appliances in use are motor-driven air compressors, rotary blowers, storage battery locomotives, side-dump tunnel cars provided with roller bearings, rock drills, etc. A mucking machine has been in satisfactory use in the tunnel heading from the Priest portal. This machine secures the spoil from the blasting operations at the heading, elevates it and delivers to tunnel cars. The use of a machine for this work in a considerable tunnel in hard rock is understood to be rated as more or less experimental. It is thought, however, to have been advantageous here in view of the shortage of labor.

At the two shafts, there are naturally two headings per shaft. Duplicate equipment was supplied in order to permit rapid work on both. One of the shafts is known as Big Creek shaft. Before 1919 had closed, this shaft had been carried down to its full depth of 646 feet and chambers at and below tunnel grade had been excavated at its foot. These chambers were starting points for the headings. A rather unusual method of handling the water was employed on this shaft. When the excavation had got down nearly half way, a considerable flow of water entered the shaft; but lower down the flow moderated. A method usual in shaft sinking proceeds by arranging a sump in the bottom of the excavation and pumping the water up from this level. Here, this would have meant, when the shaft had reached its full depth, the hoisting of a large part of the water from twice the depth at which it entered the excavation. At the depth of 330 feet a pumping station with sump was constructed and all water from upper levels intercepted and pumped out.

## Piloting the Ship with the Ears

**By George Gaulois**

THE day is not far distant when sailors will no longer fear fog and the darkness of the night. It will no longer be necessary to lose much valuable time at the entrance to a harbor, waiting for favorable conditions as is the case with our present method of piloting ships. The radio cable, developed during the world war for guiding friendly ships through thick mine fields and through narrow waterways at night, has been found to mean more in peace time than it could ever mean in military operations. This device, which is now being introduced in several leading countries, is almost certain to reduce the dangers of fog and darkness to a minimum.

Briefly, the principle of the radio cable, as it is called, is to employ a cable through which flows a 500-cycle alternating current. Ships intending to use the cable while passing in and out of waterways are provided with a pair of coils which intercept the electromagnetic waves emanating from the cable. By noting the relative strength of the waves reaching each coil, it is possible for the ship's navigator to determine when he is approaching the cable, on which side it is, and, with the sound in the head 'phones equal for both coils, when he is riding astride the cable. Once astride, it is relatively easy to follow it along and thus steer a correct course. In certain installations two cables are laid, each either carrying a current of different frequency so as to cause a difference in the tone of the signals, of the same frequency but with certain interruptions of a fixed kind so as to represent readily identified signals. In either event the navigator can determine which is the outgoing and which is the incoming cable, and in that manner select the proper one and thus avoid the danger of collision with a vessel coming in the opposite direction.

On October 6th last the United States Navy conducted an interesting public test of the sixteen-mile radio cable laid from near the Ambrose Channel Lightship to Fort Lafayette in the Narrows, or in the main waterway approaching the port of New York. With his pilot windows covered with heavy canvas, as shown in one of the accompanying illustrations, Commander Norton of the destroyer "Semmes" piloted his vessel along without a mishap or a single hesitation. He picked up the cable and guided the "Semmes" by "listening in" and steering to port or starboard as the volume of sound indicated his position.

It was the good fortune of the SCIENTIFIC AMERICAN to obtain details of the radio cable installation in New York Harbor some time before the present test. Indeed, complete details of this novel installation are to be found on page 195 of the August 28, 1920, issue. Readers who missed that number are referred to it for a complete drawing of the cable and the technical details.

In the case of the "Semmes" the installation consisted of two large receiving coils mounted above the water line on either side of the steel hull. These coils, it will be noted from another one of the accompanying illustrations, resemble nothing so much as large but empty black frames. These coils are each connected with a two-stage vacuum-tube amplifier, which amplifies the weak currents induced in the coils by the electromagnetic waves emanating from the radio cable, some four hundred times. The current, being of an audible frequency, is led directly to a pair of head 'phones. In the case of this test the cable current was interrupted so as to spell "N A V Y" in the usual telegraph code, and these signals registered in the head 'phones in the form of soft but positive clicks. A simple switch makes it possible for the navigator to listen in on either coil and so determine the relative force of the electromagnetic waves reaching each coil.

It is interesting to note that the radio cable has been developed by Earl C. Hanson, a young Californian, whose radio work dates back to the early days of amateur wireless on the Pacific coast.

## Rust Preventives

WHENEVER machinery is shipped or stored the prevention of rust upon polished surfaces is a problem. It has been an attractive problem to chemists and the market now affords several compounds designed to protect the metal surface, to cling tenaciously to it and yet be easily removed under certain conditions. One of the compounds not only prevents the formation of new oxide or rust, but makes preliminary cleaning unnecessary, takes care of any moisture that may be present upon the surface, and is even said to remove any traces of preliminary rust which may be present when the compound is applied.

## A Magnetic-Proof House for the Workers

**By Harry A. Mount**

A BUILDING of unique construction, in which not an ounce of steel or iron is used, has recently been completed in Washington for use as an experimental laboratory for the Department of Research in Terrestrial Magnetism, Carnegie Institution.

The outer walls are of double concrete construction, with 2½ inches of dead air space between. The reinforcement is brass rods, tied together with brass tie wires.

The building requirements for the research work contemplated were (*a*) unusual rigidity and strength, (*b*) non-magnetic construction, and (*c*) insulation against sudden external temperature changes.

After careful consideration the double-wall monolithic construction was adopted. The walls were built up with a Van Guilder machine. This consists of four steel plates held parallel with proper braces. The walls are built up tier by tier, a rather dry mixture of concrete being tamped in the mold, and the machine being moved on along the wall without waiting for the concrete to dry. A stucco finish is placed directly on the outside wall when completed and plaster is placed directly on the inside wall. The sill courses about the building and under the windows and the columns at the entrance of the building are of artificial stone with a fine granite and mica surface, and were all cast in place with the walls.

Further insulation against sudden temperature changes is provided by double windows and double doors and by a double ceiling of plaster-board, enclosing a dead air space of 10 inches between.

Because of the unusual requirements and specifications, particularly those for non-magnetic construction, it was not possible to secure a contract for the work, which had, therefore, to be undertaken by the Department. It was impossible, even, to secure bids for the special mill-work required, all of which had to be done in their own shop. The cost of construction, despite the increased expense necessary, was about 30 cents per cubic foot of volume enclosed, comparing very favorably with prevailing rates for ordinary lumber construction.

The equipment of the building, other than the special

# The Romance of Invention—XVIII

## William Leroy Emmet—Inventor, Engineer and Builder of Power Plants

By C. H. Claudy

AMONG the eclipsed luminaries of invention, the men so much less well known to the general public than to the technical world and particularly the engineering world, is William Leroy Emmet, of the blood of Robert Emmet, and of the staff of the General Electric Company, for whom he is a consulting engineer. In the shops of that organization Mr. Emmet has done much important work, notably in the development of the mighty turbine-manufacturing industry (the tale of that Curtiss turbine has been told in this series) and the electric drive for ships, primarily battleships, but lately for merchant ships.

Of these accomplishments more in a moment. But perhaps the greatest of all is one still in process of testing, but which its deviser and builder believes will work an enormous change, not to say a revolution in steam plants throughout all industry. This is the mercury-vapor boiler and engine. Let it be said at the outset that Mr. Emmet is extremely particular that he neither claim nor be given more credit for the development of this apparatus than he deserves. He is careful to state that others besides himself have worked upon binary vapor power plants, and that the fundamental idea of this one came to him from Bradley, himself a famous inventor. He also wants it made plain that no one in the great Schenectady plants carries a conception through to execution unaided. He has competent assistants, materials, opportunities, and so must give to the organization, as well as to the help of individuals, the credit which is due.

steam runs a steam turbine. In this condition (without the mercury turbine) the whole outfit would operate much as does an ordinary boiler and turbine, with such slight losses of heat as might be occasioned by the use of a mercury boiler and condenser instead of the ordinary steam boiler for the production of steam.

Putting the mercury-vapor turbine into the system decreases the efficiency of the whole, considered as a steam-making plant, very little, and extracts from the mercury vapor, before it is used, power to heat water to make steam from which more power is extracted. The net result is that, used in connected with such a furnace as normally is required to produce two thousand horse-power from a steam plant, the combination should produce 3,200. The mercury turbine gives 1,560 horse-power, of which 1,200 is clear gain.

The problems solved in the development of this apparatus are much too numerous and difficult even to be catalogued. Perhaps the first and most vital was the question of leakage. Mercury is both heavy and expensive and its vapor is poisonous. It is essential that throughout the system no vapor of mercury leak out, if the air about it is to be kept non-toxic. It is also essential that as little loss as possible be permitted, because with mercury at a dollar a pound and a pound being less than two cubic inches in extent, any considerable leakage would be disastrously expensive.

The cure for leakage is twofold. First, the whole system is so designed that every joint, from boiler to pipe, from pipe to turbine, from turbine to condenser

room at the power plant at Schenectady for some time, and while in many ways an experimental structure, it has demonstrated that the problems in connection with its construction and operation have been solved. Exteriorly it appears much as any steam boiler outfit with some odd looking pipes, boxes and excrescences above. Interiorly it would present a difficult problem even to an experienced steam engineer; Mr. Emmet stated that he doubted much whether even a competent power man could take it to pieces and explain the reason for its construction if he had not the key in the words "mercury vapor."

A great power company in a New England city has examined the Schenectady machine and ordered one for its own use. This is now in process of manufacture, and should be in place and operation within a year. It is obvious that if one power company gets hold of a power-developing unit which will show a thermal efficiency equal to that of the Deisel engine, while still using coal, it will not be long before others follow suit.

Mr. Emmet, who has a strong dislike for the word "prophecy" as far as he and his work is concerned, believes that there is a future for this idea not only in huge sizes but in small plants. "I see no reason why it cannot be operated efficiently for automobile trucks and even pleasure cars," he said. "I think the day will arrive when steam locomotives are equipped in this way. Any system which will save nearly half the coal used is of tremendous importance not only in saving money, but in saving the transportation of

*THERE are certain scientists, inventors, discoverers, pioneers, the very nature of whose work makes them well and widely known—the Edisons, the Wrights, the Marconis. There are others, doing just as important work, the nature of which is such that the general public hears of them but little, their renown being confined to narrower circles of engineering, philosophical or scientific societies and associations. The man in the street who could name the inventor of the "grasshopper" cut-off gear used on all modern locomotives, or recall the name of the discoverer of the moon of Mars, or explain the genesis of the long series of experiments and discoveries which made the modern electric light out of that feeble glowing bulb which first startled the world so many years ago, would be well informed indeed. It is the story of one of these great inventors of little general repute that Mr. Claudy tells us in this account of Mr. Emmett, who would doubtless prefer to be known as inventor of the mercury-vapor turbine.*—THE EDITOR.

**William L. Emmett, inventor of the mercury-vapor power plant, and the first Curtiss vertical turbine, in the development of which he played a prominent part**

But with this out of the way, it is nevertheless true that the mercury-vapor turbine, as applied to power production in connection with steam plants, is Mr. Emmet's personal contribution to applied engineering which may well rank high above either the electric drive or the development of the Curtiss turbine, the latter a contribution to the family of prime movers which practically put the reciprocating engine for electric generation out of business. Put in as brief and simple a form as possible, the mercury vapor plant is one which increases the possible efficiency of the whole from the maximum of twenty per cent, representing the best we can do in extracting energy from coal and delivering it in the form of mechanical power, to thirty-five per cent and possibly more.

In its elemental form the working of this idea may be thus described. Heat is taken from coal and made to vaporize mercury. The mercury vapor is made to rotate a turbine, in which process it makes some, but not all the heat-energy available as mechanical power. The mercury vapor is then condensed into mercury and used over and over again. In the process of condensation from mercury vapor, at a temperature of eight hundred degrees, to mercury in the liquid form, the heat is extracted from the vapor and made to produce steam in the water in the condensing system. This steam is used to turn the turbine of an ordinary steam plant.

If the mercury-vapor turbine were eliminated from the system what would be left would be a source of heat, a mercury boiler, a condenser extracting the heat from the mercury vapor and producing steam, which

and back again, is a welded joint—a "jointless" joint in other words—through which neither vapor from within nor air from without can leak because there is no place for it to leak through. Second is the provision of piped containers fitted over all places where leakage *might* occur, such as the end of the turbine shaft, and the keeping of a vacuum suction always in this container, drawing off and returning to the system any vapor of mercury which might get out.

There are engineering advantages in a system of this kind quite outside of the power-gain from a given number of pounds of coal. There is no scale to worry the steam producer, in a mercury boiler, since the mercury does not oxydize under the conditions in which it is used. The mercury vapor has no effect upon the boiler so that element of the outfit is practically indestructible. A relatively small quantity of mercury is made to serve for a large one by the rapidity of the cycle. In a design now proposed about 30,000 pounds of mercury will be used and about 230,000 pounds vaporized per hour at full load. Later designs may need a much smaller quantity of mercury in the boiler. The mercury runs in a complete cycle of liquid, vapor, turbine, condenser, liquid, almost seven times in an hour. The plant may be used for the generation of steam alone by the operation of a by-pass, cutting off the mercury vapor from its turbine and making of it merely a means of conveying heat from fire to water.

This engine, mercury-vapor boiler and steam system, be it understood, is not a theory but a fact. A complete installation has been running in the huge boiler

fuel. It may be possible to produce by this method airplane engines with weights of less than three pounds per horse-power developed, and of very high economy."

The electric drive for battleships, which is so rapidly displacing other forms of machinery designed to deliver power to the propeller has been developed at Schenectady under the personal supervision of Mr. Emmet. Lately the question has arisen as to its availability for hulls other than fighting ones, and its designer now believes that electric drive for merchant ships will be increasingly demanded and used. For a time the success which attended the operation of geared turbines interrupted the current of thought which tended to develop the electric drive for large commercial vessels, but recent improvements in electrical designs and operation of such power plants, with a very high degree of superheat, have again turned attention to this form of propulsion as perhaps the most economical method, particularly for large hulls and long runs.

The advantages are many, as stated by Mr. Emmet, and include a saving in space, which is of tremendous importance in the operation of vessels which must carry fuel not only for the outward but the return run. In such case fuel is being carried for half the distance traveled at cargo rates. Under such circumstances, the fact becomes of acute importance that the more space is occupied by propelling machinery, the less is the earning power of the vessel. There is no room for argument regarding the saving of space in an electric drive over the geared turbine. In a typical example Mr. Em-

# Painted Coffee

## A Trick of the Trade That Is Little Known Outside Brazil

By Robert C. Brown

WHAT has the paint or chemical manufacturer got to do with the coffee industry? Nothing at all; ninety-nine people out of a hundred will speak right up, and some will shout out of their turn in order to be heard, to inform you that it is preposterous to associate manufacturers of paints and chemicals with the raisers of coffee who have invested hundreds of thousands of dollars in their plantations. Some may go on and give you facts and figures about coffee, which is rapidly becoming the universal morning and after-dinner beverage. They will even tell you that coffee grows only in certain countries and that the best coffee comes from here or there and that Brazil is the greatest producing country in the world of this delicious little bean.

While the manufacturers mentioned above really hold nothing in common with the plantation raiser, they are friends, though indirectly, with Brazilian shippers of coffee. And when you mention such a fact to your friends they will immediately laugh and advise you to see a doctor for an examination of the little gray matter you have, commonly known as brains. But stick to your point, and ask if they have ever seen or drunk coffee that has been painted, then the laughter will be renewed and in all probability it will be louder and longer than before. Wait until the hilarity has subsided before launching your big guns broadside and watch your listeners sit up and take notice.

Yes, there is such a thing as painted coffee. And the painting is done right in Rio de Janeiro, the only city in the world where coffee is painted before being shipped to certain ports in this present topsy-turvy revolving globe. And not only is coffee painted, but it is also washed. Coffee is painted black, blue, green and yellow and is also bleached in some cases to give the desired hue required by the buyer. Then there is also such a thing as polished coffee.

Painted, polished or bleached coffee is not shipped to all parts of the globe for the simple reason the health authorities of some countries have had laws passed to prevent its entrance. Today the majority of this kind of coffee is shipped either to the northern ports of Brazil or to South Africa. Chile still buys some coffee after it has been treated. It is not so many years ago when painted and polished coffee was shipped to the ports in the United States as well as to Europe.

When some of the local shippers of coffee receive orders for painted coffee, the polishing or painting plants are immediately made ready for the operation. Whether the coffee was grown in the State of Rio de Janeiro, Sao Paulo, or Espirito Santo, the work is done here. The coffee in its natural state is given to one of the six firms in this city which does such work, with special machinery. To paint or polish coffee it is necessary to dump it into cylinders which are equipped with batting paddles. Each cylinder holds 702 pounds of coffee. The man in charge of the cylinders drops in the coloring or polishing material needed to give the desired finish. In painting or polishing, the material is applied a tablespoonful at a time until proper results are obtained. The batting paddles which revolve at a high rate of speed do the rest of the work.

Some coffee sold to South Africa after it has been treated has a bluish green luster to make it look like Central American or Porto Rico coffee. Some buyers in South Africa prefer their coffee to imitate Java coffee, which is yellow, and their wishes are gratified with the aid of coloring and machinery. In making black coffee for the northern ports of Brazil, graphite is used to help solve the problem. Others prefer what is known as white, but after treatment it shows up more as a cream color.

Painting or polishing cylinders hold six bags and it generally takes about twenty minutes for each operation, so working at top speed each machine can turn out approximately eighteen bags of coffee in an hour's time. After the coffee has been treated a trap door on the side of the cylinder is opened and the coffee is run into bags. After sixty kilos have been deposited in each bag, it is sewed up and final preparations are made for shipment.

The ingredients used in painting or polishing coffee are powdered aluminum, graphite, powdered paints blue and green, carnauba wax, talcum powder and ochre—the latter produces a vegetable paint.

It is only the natural coffee that is treated. On arrival at its destination and before it is sold for domestic consumption the coffee is roasted. In the latter operation the beans lose the effect of their treatment in Rio. The material used in no way affects the coffee and the majority of people could not tell by the taste that the beans had been treated.

Painted or polished coffee is a business in itself. If any one firm or individual handled this kind of coffee alone a nice profit would be made on a year's business. About 300,000 bags of this style are shipped annually to South Africa. Coffee is also washed before shipping and the process of washing is held by some as a trade secret.

Two American firms ship coffee of this type and have their own machinery for the work. In addition to this equipment one company has several separating machines to separate the different sizes and types of coffee as well as two blowers attached to the same machine to take out any sticks, dust and broken beans. In its plant there are also two mixing machines with a capacity of 11,000 bags to make one lot of the same quality of coffee, as well as two automatic weighing machines, which insure the buyer that each bag held sixty kilos when originally shipped.

When or in what city the coffee painting and polishing process came into use is not exactly known, but it is said the Germans were the first to employ such methods. It is said the coffee buyers from German houses bought coffee in the various coffee growing countries and it was then shipped to Germany for treatment. After being treated and made to look like Java, Central American or Porto Rico coffee it was re-exported to different countries where such coffee was required.

When the war broke out this industry, like many others, was lost to the Germans. There was still a demand for painted coffee and the buyers turned to the coffee shippers of this city. Here their demands were met and today Rio de Janeiro has the distinction of being the only coffee-planting city in the world, and the second greatest coffee-shipping port in the universe, bowing only to Santos.

### An Appeal

To the Editor of the SCIENTIFIC AMERICAN:

The American Meteorological Society has learned that the staff of the Zentralanstalt für Meteorologie, the national weather service of Austria, numbering with their families 67 persons, are in urgent need of food and other bare necessities of life. This establishment has always taken a conspicuous part in the development of meteorology and geophysics, under the successive directorship of such eminent scientists as Kreil, Jelinek, Hann, Pernter, Trabert and Exner, and the tragic situation of the Austrian meteorologists appeals strongly to the sympathy of their colleagues in this country. Those who desire to render aid in this emergency can send food drafts direct to Dr. Moritz Topolansky, secretary of the Zentralanstalt für Meteorologie und Geodynamik, Hohe Warte 38, Vienna XIX, or through the secretary of the American Meteorological Society, Dr. C. F. Brooks, Weather Bureau, Washington, D. C.

Washington, D. C. C. FITZHUGH TALMAN.

### Again the Tractor vs. the Horse

To the Editor of the SCIENTIFIC AMERICAN:

In your department "The Motor-Driven Commercial Vehicle," I note in an article under the date of September 18th, entitled "Horses Displaced by Tractors," the following statement: "The number of horses displaced by tractors in the corn belt is largely determined by the number it is necessary to keep for corn cultivation and other work current at the same time which the tractor cannot do."

If this is the condition of power farming in the corn belt I am greatly surprised that they are so far behind the younger agricultural district of the Southwest.

The writer is farming about 250 acres of which 25 acres is in alfalfa and the balance Puna long staple cotton. Previous to motorizing the ranch it was necessary to use fifteen head of horses and mules; at present we would not need to keep a single horse were it not for the fact that it is not advisable to use tractors on the very bad road from the ranch to the gin and even this problem would be better handled by a sturdy truck and two or three trailers than by horses.

We have one four-plow tractor of the caterpillar or crawler type and two six-cylinder, two-row motor cultivators. With the big engine we do all plowing and disking and such heavy work as moving the hay derrick, etc. The motor cultivators which can be equipped with draw bar and converted into light handy tractors in about an hour's work, or equipped with pulley for light belt work, will cut the cotton stalks, pull the harrow or drag, plant, cultivate more efficiently than horse-drawn machinery and handle mower, side delivery rake, loader and even the stacker fork, and do any odd jobs of hauling, grading, etc.

In planting the big engine will go ahead with ten-foot tandem disk and spike harrow, followed by one cultivator with drag and the other with two-row planter. In this way three men can easily plant from twenty to thirty acres a day. As to cultivators it is hard to estimate their superiority over a horse cultivator as each machine will cover about twenty acres daily; they break down far less of the plants in turning; never tire in tearing out grass and what is the greatest advantage in this hot country, will put in a full day's work in temperatures over 100 degrees where stock can hardly accomplish more than four or five hours. Also by reason of high arch construction they can keep on cultivating about two weeks after the horse-driven tools have been stopped and the crop laid by.

We employed two ordinary negro farm hands of no tractor experience to handle the machines, the writer making all adjustments and repairs. As to economy, two men did more and better work than could be accomplished with five men and ten head of stock. The fuel consumption is about 1¼ gallons of gasoline per hour and a quart of oil daily. The power plant gave practically perfect service, the only repairs being in the driving and cultivator parts. The cost is about the price of four good mules harnessed and two single-row-horse-drawn cultivators.

In conclusion, I would state that if I were obliged to give up either part of my equipment I would prefer to use horses in the spring for plowing and disking and tractors during the hot summer for cultivating and hay harvesting, exactly the opposite from what seems, as described in your article, to be the custom in the corn belt. The day of the "Motorized Farm" is not coming, it is already here.

Winterhaven, Cal. T. B. GOODWIN.

[*We are convinced that Mr. Goodwin's experience, while doubtless characteristic to some extent of his part of the country, is not representative of the country at large, and necessitates no recession from the opinion which we expressed on this subject in our issue of May 29th. Nevertheless, we are glad to print it as an indication of the extent to which the replacement of horses may go under the most favorable conditions.* —THE EDITOR.]

### The New Science

To the Editor of the SCIENTIFIC AMERICAN:

Although psychology is now regularly being taught in our colleges, there appears to be considerable mystery about what this science really is, and how it can be applied to advantage. It has been said that the several writers in this field have discussed systems of their own, thus presupposing a lack of harmony, or agreement, as to fundamental law.

There is a saying that "In Nature the obvious is seldom true." The one who got up this phrase, undoubtedly was a master of psychology, and to all intents it is half of its definition. The other half would then merely be some expedient for disclosing the real truths. If this is so, a psychologist would indeed witness a world burdened by a myriad of fallacies.

There may be a question whether the true psychologist is born or made, even as a poet or an artist is predestined, but in the meantime, if in this confused era we could obtain from psychology its truest message, its best logic, it would quite properly be in a psychological moment. A discussion of this subject would doubtless be a very live one, and would help to bring a comparatively neglected science to the front.

New York. A. F. SHORE.

# A Mechanical Age for the Farm

## What Nebraska, Through Its State University, Is Doing to Bring It About

By R. P. Crawford

PROBABLY no better proof of the fact that the farmer today has a large part in the engineering development of this country has been afforded in recent years than the dedication last April of the agricultural engineering building of the University of Nebraska. This structure, just completed at a cost of a quarter of a million dollars, is probably the finest building of its kind in the country. Let it be said that when the architects set out to draw the plans for this structure they had no precedent to go on, because a building of this kind had not as yet found a place on an American university campus. They had been teaching civil engineering, mechanical engineering, electrical engineering, and just about everything but the branches of engineering that deal especially with agriculture. It is true some colleges gave a few shop courses, but they were usually dubbed shop work or farm mechanics and were simply offshoots of the other departments.

But today agricultural engineering represents a line of work all its own. For instance, the University of Nebraska is now engaged in a series of tractor tests, the like of which has never before been attempted in America. For it is now a state law that no tractor can be sold in the State of Nebraska until all of its advertised ratings have been actually proved in a series of tests carried on at the university and a permit issued by the State Railway Commission. Heretofore tractor manufacturers have been content to make their own tests. It is true that there have been competitive tests carried on every summer but at best these were only a few field tests. But now practically every claim of the manufacturer will be tested and his advertising must live up to the actual tests.

It is undoubtedly true that the farmers of this country are entering upon one of the greatest mechanical ages that they have ever witnessed. The growing shortage of the ordinary farm hand is doing much to make the farmer turn to mechanical appliances, and, as I write, my desk is piled with letters telling what tractors have done in the Middle West, and how they have saved the extra hired hand. It is true that not in every case have they been a success, but the last few years have witnessed a great change in sentiment among the farmers of the country. This has been due largely to the perfecting of the machines. For every really successful invention that can be offered to the farmers of the country, there will be thousands ready to give it the glad hand.

The farmer is becoming better and better educated and today farm homes throughout the Middle West have conveniences that a few years ago would have been only for the cities. A few years ago a detailed survey was made of the 142 homes in Orange township, Blackhawk County, Iowa, before the present wave of prosperity had struck the country. Fifty-six of these homes were tenant homes. The accompanying table tells what the survey showed regarding modern conveniences.

Does not this record seem surprising when one recalls that more than a third of the homes were tenant homes? Undoubtedly if this survey were to be made today, the record would be still better. Of course all of these were country homes.

Just what kind of courses, do you suppose, are taught in the agricultural engineering department of the University of Nebraska? First, of course, comes the gasoline engine with the tractor and automobile leading the way. There are courses for the junior and senior in the university who expect to make agricultural engineering a life work, there are courses for the student in the agricultural high school run in connection with the college of agriculture, and finally there are tractor and automobile courses for the farmer who can take only a few weeks off in the middle of winter to study farm mechanics. These latter courses are practically the same as those offered at dozens of automobile and tractor schools throughout our country, which charge a good fee for a few weeks' instruction. The main difference in the case of the university work is that it costs the student practically nothing.

There are courses in woodwork, where the students learn to do any woodwork around the farm, and courses in forge work. And then comes rural architecture. Do you remember some of those funny old farm houses and some of the one-room schools, every one just alike? Every student here must make some practical designs of modern farm buildings. Then there is work in designing the farmstead. I wonder if the factory efficiency men who spend so much time telling just how every machine should be placed know that the farmer has to solve just such problems himself. The other day a professor of agricultural engineering figured out that if a farmer travels fifty times a day between his house and barn and the distance is 400 feet, in the course of a year he does about the same thing as walking from Omaha to New York. By having the barn 200 feet from the house he would be able to save about thirty-five days' time that in the other case would be spent walking. In fact today in all of our better agricultural colleges, the planning of the farmstead buildings is studied with as much care as the efficiency expert plans the factory.

Every type of machinery that the farm boy comes in contact with on the home farm is studied, with practical tests in the field. In the basement of the building is a large earth plat, about 12 feet wide and 156 feet long, which provides a practical testing ground for tillage implements the year round. An electrically-driven test car operates on rails at the side of the track. The implement to be tested is hitched to this car and horsepower calculations are made with a dynamometer. This has nothing to do with the tractor testing which is carried on as a separate branch of the work.

Of course every farm is equipped with pumps so that subject must also enter into agricultural engineering. In one laboratory there are five wells, one of them being of a large size and permitting of the use of an irrigating pump. There is a weir box for measuring the flow of water. Irrigation and drainage is another branch of the work. In fact, all through the Corn Belt today one will find tile drainage systems being installed and land once thought worthless reclaimed and producing bumper crops. Irrigation engineering, the application of water to the land, and irrigation laws are taken up.

For the student who aspires to become an agricultural engineer there are courses in agricultural physics and five rooms in the new building are given over to that subject. There is also a laboratory devoted especially to handling farm grains.

The main part of the building has a frontage of 180 feet and is 76 feet deep. There is a rear wing, 84 by 140 feet, which takes care of the forge shop, the motors and automobile laboratories, ignition and carburetor laboratory, grain handling lab-

## A Machine That Cleans Sewers

IN order to keep the sewers of Salt Lake City in good working condition, a special sewer-cleaning machine has been devised that is bringing good results. It is built of structural shapes and has wheels that keep the scoop from coming in contact with the bottom of the sewer. Ropes are attached to both ends of the machine to be used if any serious obstacle is encountered in the sewer, but as a usual thing the sewage is sufficient to carry the machine through safely from one manhole to the next without the use of the rope at all. Three of these scrapers are in use, being designed for sewers ranging from 42 to 64 inches in diameter. It has been found that they bring the best results when the disk has a diameter 1¼ inches less than that of the sewer. This dimension restricts the flow past the machine to an annular space of ⅝ of an inch.

**Salt Lake City makes use of several of these machines for cleaning its sewers**

## Fuel Oil Versus Coal on French Railways

THE great scarcity of coal has caused the French railways to turn to fuel oil for operating their steam locomotives. Already the Paris, Lyon and Mediterrannée Railway Company has transformed some of its motive power from coal to fuel-oil consumption, which is about to be followed by the Chemin de Fer de l'Etat, or State-owned railway, and engines at its shops at Saintes, in La Rochelle section, are now underging changes for experimental purposes.

Much attention is being directed to the announcement that the first-named railway company is planning to equip 200 locomotives for fuel oil and install numerous storage reservoirs of from 40 to 100 tons capacity at various points on its lines.

The accompanying illustrations show a test with a Pacific type French locomotive arranged for fuel-oil firing. This locomotive made a flawless run between Paris and Tours, during which the passengers were surprised by the smoothness of operation and the absence of smoke. Among the many advantages claimed for fuel-oil operation over coal on French railways are: Less work for the fireman; ease of controlling the fire, which makes it possible to economize fuel when the locomotive is not operating at full power; simple storage of fuel; greater heating capacity for the same weight; automatic shutting off of fire in case of accident, thus eliminating the danger of conflagration in a wreck.

The first shipment of 7,000 tons of fuel-oil ordered by the General Commissioner of Petroleum has been received for distribution and the Minister of Marine has announced that he will place a large amount of oil now in stock at the disposal of the commissioner.

The general interest shown in industral circles in connection with fuel-oil replacing coal should open a large field for the American product and oil-burning appliances and devices of various kinds in France. During the war large amounts of petroleum products entered the port of La Rochelle, where an English subsidiary of an Amreican concern maintains a depot of large capacity.

## Does Cold Kill Plants?

SOME very interesting experiments have recently been carried out to discover the effect of frost on vegetation. As is well known many plants are killed to the ground in the winter although the rootstocks which are protected by the soil live and are ready to shoot again with the coming of warmer weather. If it were simply the action of the cold that killed the plant the roots would certainly be destroyed for the ground in which they are situated is frozen solid. There is the best of reason for believing that it is not so much the cold as the excessive loss of moisture that really destroys the vegetable tissue. The upper part of the plant is subjected to a continuous evaporation and the loss of moisture cannot be made good seeing that the roots are in solidly frozen ground.

This evaporation during dry frosty weather is much greater than is commonly supposed. A chunk of ice weighing nineteen and a half pounds was hung among the branches of a small oak on February the 2nd. When the ice was taken down on the 14th of the month it was found to weigh eighteen pounds. All the time there had not been the smallest relaxation in the frost and, almost every day, the thermometer touched the zero point. Yet during this time a compact mass of ice lost nearly 8 per cent of its total weight in evaporation.

Later, on February 27th, another piece of ice was suspended from the tree, only this time it was placed in a pan so that no water should be lost in the event of mild conditions setting in. The ice and pan and the supporting wire weighed twenty-four pounds. On March the 24th, when only water was left, the entire arrangement weighed eighteen pounds. Thus, in a little less than a month, more than twenty-five per cent of the moisture had vanished through evaporation.

When these points are considered it will be realized that the moisture which the unprotected plant is called upon to give us is very considerable indeed. In the face of such a showing it seems altogether reasonable that the observed damage to standing vegetation in winter is a matter of evaporation. By covering the plants with soil, straw, or anything that will check evaporation, much may be done to carry the plants through the winter and this although it is not possible to keep the cold at bay.—By *S. Leonard Bastin.*

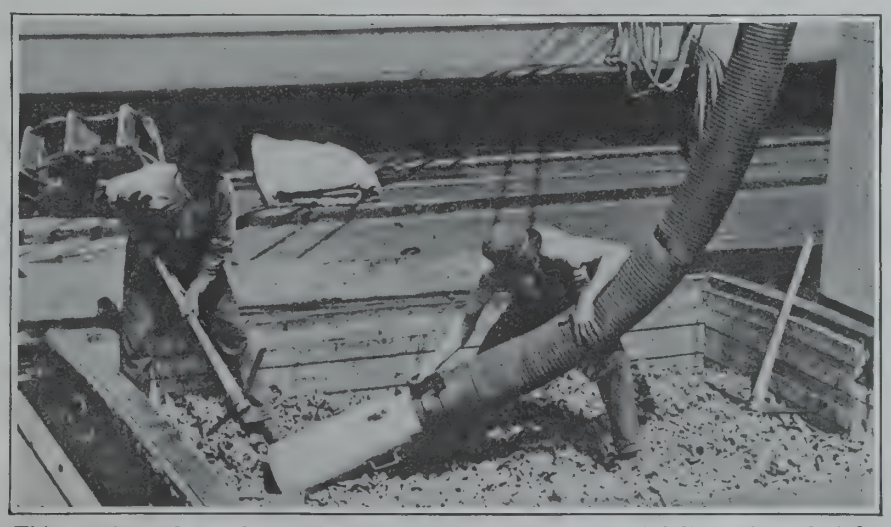
## Carbonic Acid as a Fire Preventer

IN spite of all precautions fires frequently occur in places where large quantities of coal are stored. Under present conditions such coal fires are a source of particular danger, where so many war stores are still lying around. The German *Steam Boiler and Engine Driving Journal* now states that at a large coal dump in Dortmund the coal is now being stacked up in conjunction with the use of carbonic acid, the acid being used in the same way as is commonly employed when coaling ships. Carbonic acid is, of course, much heavier than air and thus always fills thoroughly even the lowest parts of the coal bunkers. The process is especially suitable when storing coal in high receptacles.—By *Arthur J. Keane.*



**This suction tube sucks up the copra in the ship's hold and delivers it to freight cars some distance away**

## Suction as an Unloader of Ships

THE same force which enables the housewife to suck the dust out of carpets and draperies and dusty corners is now being applied in more ways than one to simplify the work of the industrial world. One of the latest applications is to unload ships carrying copra and other similar cargoes.

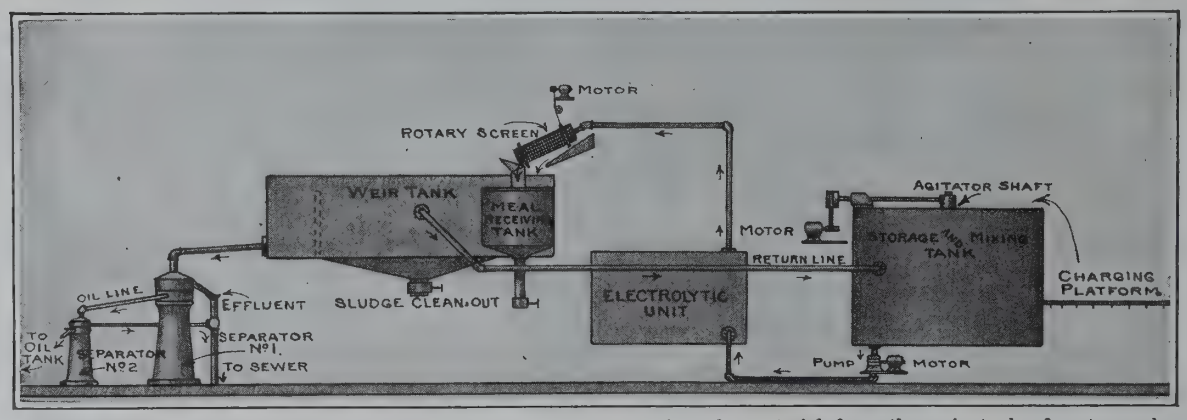
Our illustration shows the end of a suction tube at work in the hold of a steamer loaded with copra. The suction tube sucks the copra and deposits it in freight cars standing on tracks some distance away. This system has just been installed at the Parr terminals in Oakland, Cal., and is reported to be operating successfully with a very appreciable saving in both time and labor.

# Extracting Oil by Electrolytic Action

## A Recently Developed Process Which Bids Fair To Be of Economic Moment

By Robert G. Skerrett

ONCE again we have an example of laboratory research put to commercial service, and science shows us how we can greatly reduce our present wasteful practices and amplify to a notable extent the measure of marketable output obtainable from a given quantity of raw materials. This step forward is the direct result of a discovery made by George D. Rogers, a young chemist, graduated from the Massachusetts Institute of Technology. His professional work brought him in touch with the fish-oil industry, and it was not long before it dawned upon him that the prevailing methods had decided shortcomings.



Separator No. 1 is really a skimming apparatus which does not quite free the material from the weir tank of water and a percentage of the suspended solid matter. Separator No. 2, however, serves the purpose of a clarifier and discharges only clear oil. Should the material in the receiving section of the weir tank give evidences of incompletely treated matter, the charge can be returned to the mixing tank for a second run through the electrolytic unit. Ordinarily the breaking down in the unit would be sufficiently effected in one passage

**Operative cycle of the electrolytic process for the extraction of oils**

Mr. Rogers set himself the task of finding means by which more oil could be extracted from the primary stock; and he seems to have succeeded far beyond his expectations by evolving a process capable of much wider adaptation than at first imagined. The work-sized demonstrating plant now in operation at Gloucester, Massachusetts, is proving extremely efficient, and today is handling a variety of fatty or oleaginous substances in a fashion that reveals the usefulness of electricity in a new field. It is competing with the try-pot, the water bath, and the steam-jacketed kettle, and the results are somewhat revolutionary and of much economic significance.

We learn from the latest figures supplied by the U. S. Bureau of Fisheries that our annual yield of "aquatic oils" of all kinds has averaged for a number of years about 5,400,000 gallons. The importance of these oils has increased by reason of their widening applications, especially since methods of preparation have been developed, such as sulfonation, oxidizing, heat treatment, and hydrogenation, which have made them fit or better suited to employment. We can probably best illustrate what this latest process promises if we explain the usual procedures in the extraction of oil from cod livers, for instance.

It is officially said that "sun-tried" oil represents anywhere from 20 to 40 per cent of the total quantity of oil produced. It is superior to that rendered by cooking. It is obtained by putrefaction of the livers and, as may be imagined, the natural process takes a somewhat protracted period. Very little of this cod-liver oil is used for medicinal purposes. The quicker procedure consists in cooking the livers, and in this two general methods are followed: First, by a water bath, a wood or coal fire supplying the needful heat, and, second, by steam, in either case, the rendering takes from 2 to 3½ hours; and the temperature at no time should exceed 200 degrees Fahrenheit. It seems that it is absolutely necessary to abridge as far as possible the time the livers are subjected to heat in order to secure a really choice grade of oil.

According to the U. S. Bureau of Fisheries: "For the production of the clearest and lightest medicinal oil, the livers should not be exposed to a greater heat than 160 degrees Fahrenheit, and that only for about 45 minutes. This, however, is not feasible because the quantity of oil produced in that case would be too small to make the business profitable. The time must, therefore, be extended as far as practicable without detracting too much from the quality." So much for the state of the art. Now let us see what the laboratory work of Mr. Rogers and the mechanical equipment designed by Robert P. Bennett represent in the way of an advance.

From the time the raw cod livers are placed in the mixing tank and the oil issues from the final separator the procedure does not take at the outside more than three minutes! The actual release of the oil from the fat cells is accomplished in an electrolytic unit, and from that point on the process is devoted to the separation of the oil from the water, sludge, solid matter, etc. The extraction of the oil amounts to almost 100 per cent of the oil content in the raw livers; and the passage through the electrolytic unit takes less than a minute.

*ELECTROLYSIS bids fair to affect profoundly that diversified industry which is now engaged in the extraction of oils, oleo, and tallow from fatty sources. These products play a prime part in our daily life in numerous directions. As foods, as medicaments, as the foundation of soaps, as dressings or fillings for leather, as lubricants, as ingredients in paints, and so on, we use each twelvemonth many millions of dollars' worth of these commodities, and the demand is steadily growing. And that is why we have asked Mr. Skerrett to tell us about a new and remarkable process for the extraction of oil by electrolytic action.*—THE EDITOR.

The electrolytic unit of the apparatus consists broadly of a rectangular box of steel containing a number of straight sections of 2-inch pipe joined to one another by rubber hose. Each of these pipes, known as "coils," carries a concentric rod of carbon one inch in diameter, reaching from end to end of the metal tubes. This leaves an annular channel half an inch wide around the carbon rods, and through this the macerated liver and salt water are driven by a gear pump. The mixture goes successively through all of the "coils" before issuing from the electrolytic unit. The purpose of the hose connections is to insulate from one another the various pipes or cells.

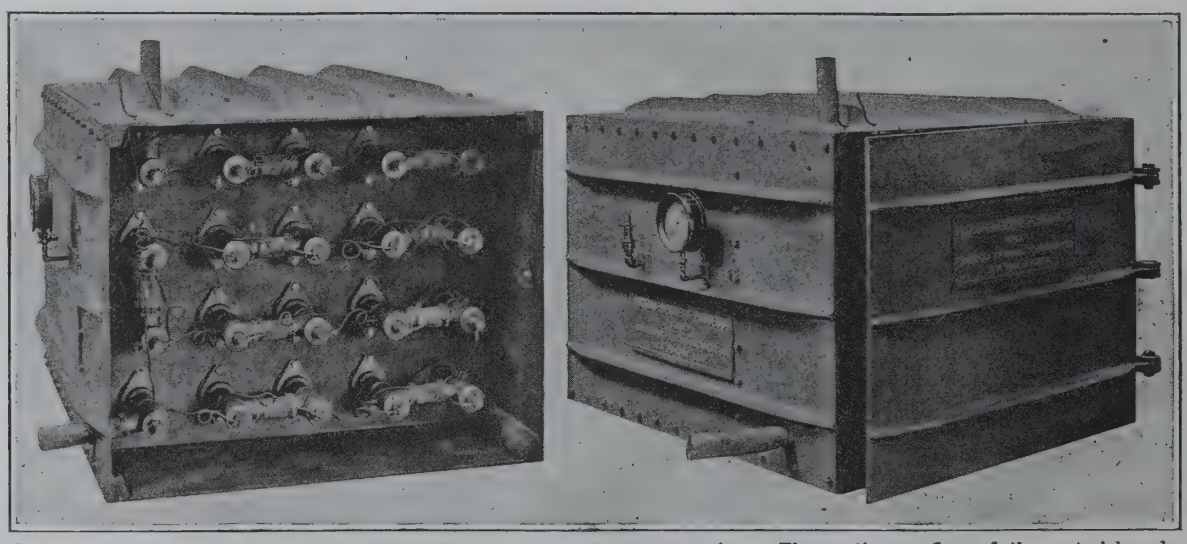
Each carbon rod is insulated from the enveloping metal tube, and the electrical connections for each pipe and each rod are independent, the carbon rods forming negative electrodes and the pipes positive electrodes. When current is flowing, the circuit is completed through the material carried by the electrolyte. The electrolytic action thus induced effects the extraction of the oil, by causing the fat cells to discharge their contents. The explanation of the phenomenon is that the passage of current between the electrodes destroys the balance between the electrolyte and the matter held by it in suspension, and in consequence an osmotic force is set up which brings about the bursting or breaking down of the protein envelope of the fat cells. There is thus recovered about 99.75 per cent of the oil present in the livers.

To appreciate the significance of the electrolytic method, it is said that the "sun-tried" livers yield only from 15 to 35 per cent of their oil content, and fully two-thirds of this is made up of the poorer oils. Where the cod-liver oil is extracted for medicinal purposes by steam-jacketed kettles or the water bath, it takes quite three gallons of livers to produce a single gallon of oil, and even so all of the oil is not fit for medication. By the Rogers-Bennett process, the oil recovered at any time is of a uniform standard—the grade varying only with the age of the livers. Age in this case means the time elapsing between the catching of the fish and the delivery of the livers for rendering. In common practice, the livers must be taken in hand within twenty-four hours after the fish have come from the water. On the other hand, a fine grade of oil, meeting in every way the requirements of the United States Pharmacopœia, has been produced by the Rogers-Bennett system from cod livers six days old, and excellent oils have also been obtained from livers four to six weeks old.

The only heat used in the cycle of the Rogers-Bennett process is employed to stimulate the easy flow of the macerated material through the electrolytic cells. To this end, exhaust steam fills the space around the "coils," and the maximum temperature is about 155 degrees Fahrenheit.

The discharge from the electrolytic unit has the character of an emulsion, and is carried to a rotary screen which diverts most of the solid material into a receiving tank while the oil and finer solid matter enter a weir tank where the sludge settles and the oil and water go on to the sepa-

(*Continued on page 440*)



*Left:* An interior frontal view of the electrolytic unit with the door swung clear. The continuous flow of the material under treatment, from coil to coil, is made possible by rubber couplings. The rubber hose is used for the purpose of thus electrically isolating contiguous coils from one another. The apparatus can be taken apart whenever necessary to facilitate cleaning and replacements. *Right:* A 20-coil electrolytic oil-extraction unit showing intake pipe at top of case and discharge conduit at the lower left side. The front is hinged to permit ready access to the electrical connections of the various coils.

## Melting Gold Coin at New York Assay Office

AS we pass down Pine Street and see the low classical building which houses the Sub-Treasury, we see an inclined wooden path leading to a forbidding looking building whose iron bars suggest a modern jail, but once inside this building we are in Aladdin's cave and hundreds upon hundreds of billions of dollars are in evidence. This unpretentious entrance would in the normal course of events have been closed and sealed up and the new and beautiful façade and entrance on Wall Street would have been open if it had not been for the bomb outrage which is still so recent in the minds of all. The explosion took place directly in front of the Wall Street entrance of the Assay Office and there is little question that as an objective the Assay Office had equal honors with the Morgan bank across the street. The destructive bomb or series of bombs tore pieces out of the stone, destroyed all the windows and warped and deformed the iron grills and other ornamental work in the beautiful office which was to have been devoted to the use of the public. Fortunately, owing to delays of various kinds, there were practically no employes in the new section of the Assay Office, or the death toll, already large, would have been increased by fifty or sixty. It will take many months and a considerable sum of money, which, unfortunately, Congress must appropriate, before the signs of havoc can be eradicated. The old building is not an old building at all; in fact, it is only about ten years old, but is called the old building in contradistinction to the new building which, it is hoped, will be opened by July if Congress appropriates the necessary funds to repair the damage. The older building will be used exclusively for melting and refining, while the new building will be devoted to the assay laboratories, the public reception rooms for those who bring their gold to be assayed, executive offices and several floors of vaults which are so urgently needed. Our cover presents a most interesting phase of the work of the Assay Office—the melting of coins into gold bars.

During the war period hundreds of millions of dollars of foreign gold coin, principally British sovereigns, Japanese yen and French francs found their way to the melting pots of the United States Assay Office at New York. A difficult problem presented itself in the prompt melting and storing of this vast treasure.

Regulations governing the handling of these deposits were so modified as to work no injustice to the depositor. Payment of 99 per cent of the value of the deposit was made, ascertained by their being weighed immediately after receipt when presented in sums of $1,000,000 or over. Of course such deposits come only from banking houses of recognized standing and when advantage is taken of this regulation the depositor is required to give guaranty in writing of the integrity of the coin. With the old regulation of a 90 per cent advance after weighing, the interest loss to the depositor would be considerable in a transaction involving several millions of dollars. Another important change authorized, was the reporting by the assayer on deposits of not less than $5,000 to one-tenth of one-thousandth instead of one-quarter of one-thousandth.

The physical operations involved in the handling of these deposits are as follows: The coin, after removal from the sealed boxes in which it is shipped, is weighed to .01 ounce in drafts of approximately 2,300 troy ounces. The advance payment is made to the depositor after this weighing and is based on the fineness of the coin deposited.

Drafts are delivered to the melting room and are shoveled into graphite crucibles with long-handled scoops. Three drafts or approximately 7,000 troy ounces (480 pounds avoirdupois) constitutes a melt.

Melting is done under cover of charcoal (powdered) to prevent oxidation and the molten charge is dipped from the crucible and cast into bars weighing approximately 340 ounces each. Each bar is given the melt number and returned to the receiving room and weighed to determine the after-melting weight, upon which the final payment to the depositor is based. On new coin the average melting loss is .25 ounce per 1,000 pounds melted. After each third of the melt is poured a dip sample is taken for assay and this is checked by a chip taken from the first and last bar of the cast. The pictures on this page, as well as our cover drawing, represent stages in the assaying process.

The bars, known as certificate bars, are properly marked with weight, fineness and value and stored away in the vaults and gold certificates issued against them. We are indebted to the Hon. Verne M. Borie, Superintendent of the Assay Office, and Mr. E. J. Wager, the melter and refiner, for courtesies in connection with the present article.

## Can Snakes be Charmed with Music?

THERE is no foundation in fact for the common belief that a snake can be "charmed" with music, according to Allen S. Williams, director of the Reptile Study Society of America. Mr. Williams bases his opinion on a series of experiments extending over a period of nearly twenty-five years.

"I have tried every sort of music," says Mr. Williams, "from a tin whistle with note holes in it to a symphony orchestra, and have used as subjects nearly every variety of snake, but have yet to note any response on the part of the reptile.

"Once with a very beautiful panther snake, which because of his red robe we called Richelieu, I thought I saw signs of response, so I laid him on top of the piano while I played. He looked at me steadily for a moment and then slipped off the piano and started for a mouse hole which had once yielded him prey."

In another experiment, Mr. Williams surrounded a violinist with more than 200 snakes. He noted no response to the music from any of them. The belief that snakes are responsive to music probably originated, Mr. Williams believes, from the East Indian fakirs.

These men play on a peculiar reed whistle, swaying their bodies as they play. A snake, usually a hooded cobra, erects its head from a basket before the player and sways with the rhythm of the music. The explanation, Mr. Williams says, is not in the music but in the swaying of the musician's body.

"The vision of all snakes," he says, "is very defective. It has been said that the boa constrictor cannot see as far as his own length. I believe that is an exaggeration, but my own experiments have shown me that the snake sees very little of form or color. The thing which most attracts him is motion. I have seen snakes violently startled by the flapping of a window curtain.

"In the case of the Hindu fakir, the snake follows the motion of the man's body trying to see what is before it, either because it fears the thing might harm it or may prove to be something good to eat.

"I have obtained about the same result with other snakes, with and without music, but the hooded cobra makes an especially good subject for this trick because it has the habit of "sitting up" about one-third of its length.

"In fact the snake, if it had any emotions, would find them hard to express. A dog can wag his tail and actually laugh when he feels like it, but a snake cannot wink an eye for it has no eyelids. More intelligence is usually attributed to a snake, too, than it actually possesses. I believe it to have the least intelligence of the reptiles, both lizards and turtles being above it."

Another fallacy which Mr. Williams believes he has exploded is the belief even among some scientific men that human beings have a hereditary fear of snakes.

"I have never found a little child which was afraid of snakes," he says. "On the other hand children seem to like them. I have found, too, that women are less afraid of snakes than men."

Pouring molten gold into iron molds

Weighing 2400 ounces of gold

## A Non-Inflammable Timber

A PROCESS has been made public in England by which timber is made fire-proof. It consists in submitting the wood in a closed cylinder to a steaming and vacuum treatment, which removes the air and moisture in the pores of the wood and vaporizes the sap water. The wood is then impregnated under hydraulic pressure with a solution of fire-resisting chemicals, which replace the elements driven out by the preliminary treatment. Finally the water of the solution is dried off, and the chemicals in minute crystal form remain embedded in the fibers. The effect of this treatment is explained as being that on the application of heat the crystals expand and form a glossy coating, which excludes the oxygen of the air and prevents its combination with the wood, thus rendering flame an impossibility. The higher the temperature, the more the crystals expand, and though in time the chemical action of each crystal becomes exhausted and the wood becomes charred fresh crystals come into play, and though the wood may eventually be charred completely through, no flame will be generated. Wood treated in this way does not differ in appearance from wood that has not been treated, and it is claimed that it does not corrode nails or screws.

# The Service of the Chemist

*A Department Devoted to Progress in the Field of Applied Chemistry*

Conducted by H. E. HOWE, Chemical Engineer

## The Electric Furnace in Metallurgy

ATTENTION is called to a reading list comprising some 87 pages of references on the Electric Furnace as Applied to Metallurgy. This is a contribution by C. J. West and has been reprinted from the transactions of the American Electro-Chemical Society, the paper having been presented before the April meeting of that society. The author has attempted to include all the important references since 1900, the date at which electric furnaces were becoming established in the wire and steel industry, and, beginning with 1907, references to Chemical Abstracts are given in addition to enable the reader to eliminate many of the references which might not fit his particular needs. Compilations of this character, involving as they do patient search and tedious examinations, are always valuable contributions and the information that such a list is available will be welcome.

## Synthetic Ammonia

WHILE an attempt is being made to have legislation enacted to help establish a fixed nitrogen industry in America, primarily through the operation of Government plants, remarkable progress is being made abroad. According to the report of the American Chamber of Commerce in Berlin it appears that synthetic nitrates have been developed to the point where Germany is now entirely independent of Chile. By the Haber and cyanamide processes she will not only be able to supply her own requirements but expects to export fixed nitrogen in the near future.

In France the recent researches of Claude have caused quite a commotion, he having succeeded in producing pressures of more than 1,000 atmospheres by methods applicable to industrial uses. He has shown that it is not only possible but indeed easy to attain such pressures and has now applied them to the production of synthetic ammonia. Under the conditions which he obtains, hydrogen and nitrogen combine with such facility that a large output is possible with a comparatively small installation. In the Haber process approximately one-third of a gram of ammonia is produced per gram of catalyst, whereas Claude obtains a yield of ten grams.

## De-tanning Chrome Leather

A BRITISH patent has recently been issued covering a process whereby scrap leather may be de-tanned and the resulting material used for the manufacture of glue and gelatine. The chrome leather is first immersed in a solution of an organic acid, such as phthallic, lactic, tartaric, oxalic, or other organic acids containing two or more hydroxyl groups. The chromium may be recovered from the resulting solution and the de-tanned material treated in the usual manner for making glue or other similar products.

## The Fruit Fly

IN a recent number of the *Chemical Bulletin* David Klein comments upon a popular article in the *Scientific Monthly* for December, 1919, in which Dr. Loeb discusses the results of his experiments with the fruit fly, hatched and bred aseptically. One interesting finding is the duration of life appears to be a function of the temperature to which the fly is subjected. Thus at 30°C. its average life is 21.15 days; at 20°C., 54.3 days; while at 10°C. it is more than 177.5 days. As Dr. Klein observes, if temperature were a factor of equal importance in human life, one would be able to live a prolonged existence at the North Pole and but a brief period at the equator, thus giving him the choice between a long, monotonous existence and a short, merry one. We may find some time that life may be written as a chemical equation and that the sum total of the chemical energy of a life-time is a constant and the length of life dependent upon the rate of its utilization.

## Industrial Alcohol

ATTENTION is called to an article in the March 17th issue of *Chemical and Metallurgical Engineering* on this subject by Burnell R. Tunison. This article treats of industrial alcohol under the new law and regulations, and in addition to defining the various types of alcohol, includes an interesting table of authorized formulas for specially denatured alcohol, and another table giving the products and industries authorized to use specially denatured alcohol. The extent to which industries now depend upon alcohol is indicated by the list of more than a hundred products of very diverse character. The alcohol situation is complicated by scarcity of raw materials, unusual demands and difficulties of transportation and marketing brought about by the difficulties attending the enforcement of prohibition legislation.

## Paper Fibers

TWO promising new fibers for strong paper are reported—one consists of the macerated bark of the cuazuma tree, which occurs in Mexico, and the second the leaves of the doum tree, which grows along the coast of Morocco. The bark in question is sometime 20 to 30 centimeters in thickness and the fiber from it can be produced at a low cost. The doum is a dwarf palm that matures rapidly and the estimate is that 100,000 tons may be available annually. The pulp produces 75 per cent of fiber, which has a satisfactory felting power, great tenacity and suppleness.

## Glue and Gelatine

AN Australian patent has recently been granted on a process to produce glue and gelatine from horns and bones, which are subjected to a solution of hydrochloric acid for a period of five days, the step being repeated until the material has been treated five times. After a thorough washing in cold water, the material undergoes two twenty-four-hour applications of a lime solution, after which it is washed again, dried, and boiled from twelve to eighteen hours. The thin liquid may then be skimmed off and dried and comprises pure gelatine, while the thick liquid contains the glue.

## Pyroxylin

AN American patent has been granted on a process devised to decrease the inflammability of pyroxylin. Commercial pyroxylin is dissolved in methyl alcohol containing five per cent of acetol. The solution is then diluted with carbon tetrachloride and chlorinated in the presence of a carrier such as zinc or tin chloride, until five to eight per cent by weight of chlorine has been absorbed by the pyroxylin. The solvents may then be evaporated off and the chlorinated pyroxylin washed, neutralized and dried in the usual manner.

## Aluminum from Labradorite

A PROCESS has recently been developed in Norway for the extraction of alumina from labradorite. The mineral is dissolved in dilute nitric acid made locally by the fixation of atmospheric nitrogen, and the impurities remain in the residue. Evaporation and heating to a point at which the aluminum nitrate left is decomposed, is carried on and the calcium and sodium nitrates are dissolved in water, leaving a pure aluminum oxide. Pure labradorite contains about 30 per cent alumina, which is equivalent to 16 per cent aluminum. It must be that this mineral as found in Norway differs from that occurring in America, as the labradorite usually found here is not sufficiently soluble in nitric acid to give promise of working the process on a commercial basis.

## A New Abrasive

THERE has been need for some time for an abrasive having extreme sharpness, long life, uniformity and fast, cool-cutting ability. In addition it should be possible to form a wheel from this material that would be what is known as "open" and brittle in its structure. Research has at last provided such an abrasive, composed of large alumina crystals and the impurities present probably do not exceed 1.5 per cent, which is very much less than in the case of the ordinary type of aluminous abrasive. When a rupture occurs in such a large abrasive grain it means that a crystal of alumina has been actually fractured, the principal result being the provision of new sharp-cutting points and edges.

## Cottonizing Vegetable Fibers

A PROCESS for cottonizing such fibers as jute, hemp, flax, and any vegetable fiber which has a woolly or hair-like feel, has been reported. The waste fibers are passed through a device which tears them apart; they are then crimped, but the process does not reduce the larger fibers to the point where other than coarse yarns can be spun. These fibers thus treated by a mechanical process are not so smooth as those produced by chemical treatment, but they produce greater strength largely on this account. The chemical process employs both sodium hydroxide and chlorine, as well as oil soaps and peroxides, which develop nascent oxygen. The dry fiber is washed in a way to force the fluid through the material and in order to make this treated fiber more suitable for spinning a strong, cold caustic soda solution is recommended, after which it is washed in hot water.

## Chlorine and Influenza

DR. CHARLES BASKERVILLE, in speaking on this subject, points out that while the data thus far obtained do not warrant drawing conclusions, such facts as have been established would indicate to the medical man the advisability of trying experimentally dilute chlorinated air as a prophylactic in such epidemics as so-called influenza. Dr. Baskerville determined to what extent workers in plants where small amounts of chlorine were to be found in the atmosphere were affected seriously by influenza and many of those from whom information was requested expressed the opinion that chlorine workers are noticeably free from colds and other pneumatic diseases. One plant in which fifteen per cent of the employes were infected reported no cases in the chemical building, where chlorine was produced, nor did any occur among the employes in its bleaching room.

## Light Alloys

IT is interesting to note that the majority of the light alloys in the United States are aluminum-copper, whereas abroad aluminum-zinc is more often found. This is said to be due to our lack of information regarding the aluminum-zinc series, and to supply the missing information, extensive research work has been undertaken on this class of materials by one of the large zinc-producing companies. The production of aluminum is rapidly increasing in the United States, and it is predicted that by 1930 the total production will equal, if indeed it does not exceed, that of copper. Aluminum as an element in die-casting has caused a number of difficulties, which are, however, being gradually overcome, and at present 150,000 castings can be made from a single die. There is no question but that aluminum has come to stay as an engineering material, the possibilities of which have by no means been exhausted.

## Heating Wood Before Gluing

IN its Technical Notes the Forest Products Laboratory points out that in joints of small area, where the gluing is done in warm rooms in the absence of a draft and the wood itself is at room temperature, little is to be gained by pre-heating the wood. In fact, under such conditions, heating may be detrimental, since the glue will be kept thin and squeezes out when pressure is applied. However, when joints several inches each way are glued, pre-heating has a distinct advantage and unless heated, the joints develop their full strength only in spots. It has been found that joints of large size can be produced of uniform high strength if the wood is heated for from ten to fifteen minutes at from 120° to 130°F. just before gluing. The heat prevents the glue from chilling and keeps it liquid until pressure is applied. The rate of set is retarded, full joint strength being developed in ten hours in mahogany and more than twelve hours in red oak and maple, whereas cold-glued joints reach their full strength in less than eight hours.

## Chemistry and Brazilian Imports

A LAW has been passed in Brazil providing for the establishment at once of laboratories at ten of the ports where all kinds of fabrics, chemical products, drugs, pharmaceutical preparations, canned meats, and fish and all products used as foods or in the preparation of foods and drink are to be tested. Later other laboratories are to be established in custom houses at other ports, and a fee of 2 per cent of the total import duties will be levied to cover the costs of making the analyses. The object is to prevent the introduction into Brazil of articles injurious to the public realth.

## San Francisco's Traffic Convention and Street Safety Show

By C. W. Geiger

FOR the first time in the history of the United States a foreign government has "sat in" for the purpose of creating a common police law, for the United States and Canada. Both nations will be allied in framing this great and beneficial law that will enable the motorist to travel from the Atlantic to the Pacific Coast, either through the United States or through Canada, and meet with only one general condition everywhere, thereby relieving the motorist from the embarrassment and annoyances that he must now endure in extensive travel.

The primary purpose of the Third Annual Convention and Safety-First Exposition of the International Traffic Officers' Association at San Francisco is to obtain an international viewpoint on traffic conditions and crystallize this viewpoint into a uniform Motor Vehicle Act to be presented to the various legislatures at their next sessions. The need for uniform traffic regulation is great, and universally known, so it is hoped that out of this conference and meeting of those who are thoroughly conversant with all traffic conditions, such uniform legislation will come. It must be so broad in scope that it will take care of the pedestrian as well as the motorist, and in such shape that it can and will be enforced to the benefit of the people, making our streets and highways safe for all users.

**A test of braking power, in which the car going 20 miles per hour was brought to a standstill in six feet**

The street in front of the Exposition Auditorium was turned into an outdoor laboratory for every sort of traffic test. The pavement was even hosed down by the fire department for the proper slipperiness for a skidding demonstration. One test arranged was to show the proper distance in which a car should stop in an emergency, the demonstrating cars turning a corner and pulling up short at various speeds. At a speed of 15 to 20 miles an hour a car was brought to a dead stop in six feet. For these tests the street was marked off with white paint, indicating to the driver where to start his stop.

A hundred or more automobile offenders got a novel warning when the traffic policemen in the down-town region of the city gave them formal printed admonitions to go take a look at the safety-first stunts, where there was displayed what is probably the largest and most complete exhibit of safety-first devices for automobile traffic ever shown in this country. Arm wig-wagging, judging from the exhibits, is already a thing of the past, superseded by the little arrow signals which are attached to the windshield, or by rear colored lights, or by work signals flashed to the accomplishment of a bell. The blinding glare of approaching headlights is dimmed by an adjustable violet glare-shield attached to the steering wheel; by violet-ray lenses; or by lenses supplied with a fin or shelf or specially treated glass which acts as a shield between the light and the eye of the approaching motorists. Prominent among the safety devices is a safety bumper which automatically stops the car and sounds a horn when it strikes another auto. This bumper promises to make safe the lives of little children caught unawares as it stops within a few feet when going at twenty miles an hour, and is too low to the ground to admit of anyone being dragged beneath it. Everything is done mechanically so as to leave the driver as free as possible to guide his car, and yet make it simple to meet the requirements of the motorists laws.

Other notable features of the exhibit are the safety devices to guard the car against theft. These include locks for the steering wheel, which defy picking, and chain tire-locks.

In keeping with the traffic convention a splendid traffic regulator, on the order of the railway signal systems, was exhibited for use on city streets. It consists of a semaphore placed on posts at the intersection of streets, and provided with lights, bells and

(*Continued on page 440*)

**The auditorium in which the safety-first exhibition was held, showing a group of the exhibits**

## Something New in Gasoline-Driven Plowing Machines

By James H. Rodgers

WE are told that there is nothing new under the sun. In a broad sense this is probably true, but variation in the application of certain well recognized principles frequently creates machines that may, without exaggeration, be properly classed as extremely original. Such is undoubtedly true of the plowing machine herewith described and illustrated. What, at a distance, appears to be some queer development of a flying machine, with its wings outstretched, resolves itself, at closer range, into an interesting but distinctive type of plowing machine.

To the person unfamiliar with mechanics, the initial sight of such a machine is somewhat astounding, but keener observation, particularly when the plow is in motion, impresses one with the vast possibilities of such a unique machine.

During the war, and since, the factor of man-power for agricultural purposes has been rather a serious problem. As a partial solution to this question the adoption of machinery capable of performing more work with less labor appeared to be the best means to the end sought.

The illustrations show several views of this new plowing machine, the design of which is out of the ordinary, and demonstrates a radical departure from the usual present day practice of tilling the soil. The designer of this machine, Mr. L. A. Desy, civil and mechanical engineer of Montreal, Quebec, has made several successful preliminary trials on a farm close to Montreal, and the initial performance has more than met the fullest expectations of the builder.

**Two views of the machine that puts plowing on a quantity basis by means of an endless belt of plowshares**

Unlike the ordinary plow, where the furrows are made parallel to the travel of the machine, the method of operation in this plow causes the plow shares to move at right angles to the forward movement of the tractor, resulting in a furrow that converges toward the center at an angle of about 20 degrees, leaving the plowed land with a herringbone appearance.

In operation, the plows travel toward the center of the machine, seven of the plows on each side being in the ground at one time. The width of the land covered at one passage of the machine is approximately 40 feet.

When turning at the end of a field the two plow arms can be raised so that the plow shears and the disks are clear of the ground, and the machine can be turned in its own length by means of the steering wheel and the caterpillar tractors. When desired, a start can be made from the very end of a field, as the tractor can be backed right up to a fence, if necessary. The machine, however, is intended for Western plowing, where large tracts of land are under cultivation.

The machine shown has an approximate weight of eight tons, and under tests on land that had not been plowed in several years, it covered about 30 acres in a day of ten hours.

# Inventions New and Interesting

*A Department Devoted to Pioneer Work in the Arts*

**This simple tool twists a wire about a bag to tie it**

## Making a Twist of the Wrist Tie a Bag

WIRE for tying bags is being used to a large extent. So interest attaches to a special wire-tying tool that has lately been devised and that makes possible the tying of large numbers of bags during a working day. Wires are cut of sufficient length for a perfect tie and no material is wasted. A workman once taught the trick of the twist necessary to bend the wire, can fasten securely many more bags than when using twine.

## Briquets from Coal

PUBLISHED reports say that the Lignite Utilization Board, which has been for months experimenting with the problem of cheaper fuel for domestic use from the low-grade coal found in southeastern Manitoba and Saskatchewan, has arrived at a satisfactory manufacture of briquets.

The chairman of the board has expressed the opinion that the engineers have succeeded in finding a system for the manufacture of briquets that will probably produce fuel equal to the best grade of the United States anthracite coal, and which will be even more satisfactory for domestic use.

The board has decided to erect an experimental plant with a capacity of 30,000 tons a year. The plant will doubtless be located near the mines operating in Saskatchewan, close to the Manitoba boundary.

The chairman of the board further says that a careful analysis of the costs leads to the belief that briquets can be manufactured and loaded on cars at the plant at about $7.50 a ton.

It appears that the Canadian Utilization Board entered upon its work over a year ago and was organized as a result of an agreement between the Dominion Government and provincial governments of Saskatchewan and Manitoba. The Dominion Government appropriated $200,000 and the provincial governments each $100,000 to meet the expenses of carrying on this work.

**A transformer in the base of this night lamp reduces 110 volts to 6 volts**

## Use of Potato Flour in the Netherlands

AS a result of the continued high price of wheat flour it is announced that the Government of the Netherlands is arranging for the mixture of potato flour, manufactured in the Netherlands, with wheat flour from the United States to augment and cheapen the supply of breadstuffs in the country. It is announced that the Government has recently purchased from local manufacturers a stock of 20,000 metric tons of the potato product which it proposes to mix with the imported product. The potato flour bought by the Government costs 6.4 cents per pound as compared with practically the same price for wheat flour at the present time, but a somewhat higher price on an average for some time past. It is expected that by mixing the potato product with that of wheat any further rise in the cost of bread can be prevented, though it is understood that the fixing of a maximum price for bread will again be undertaken if that becomes necessary to prevent any serious rise in the cost of this staple food to the Netherlands people.

Both potato flour and potato starch have been used as constituents for bread during the war. There is considerable indisposition on the part of the Netherlands public to use flour containing the potato starch which, particularly during the war, was usually not of good quality, but it is anticipated that there will be no complaint as to the use of the potato flour which, when properly mixed with the wheat product, is said to make very good bread not much different from that in ordinary use in the land of dikes and canals.

## A New Light That Costs Next to Nothing

BY the ingenious combination of a small step-down transformer and an automobile incandescent bulb, an inventor has recently introduced a night light which costs practically nothing to operate. Indeed, this light, operating on the standard alternating current supply lines, hardly affects the usual meter, hence the cost is negligible.

The principle of this new light, which is shown in the accompanying illustration, is merely the stepping down of the 110-volt alternating current to 6 volts in order to supply the necessary current to a 6-volt 2-candle-power bulb. The transformer is placed in the base of the porcelain body of the lamp. A bayonet type socket holds the lamp, which can be flashed on or off by the switch shown in our illustration. The hood of this attractive little lamp is so designed as to direct the light rays where they will not trouble the person making use of the lamp.

## A New Use for Rubber Tubing

OF the many methods employed to keep the milk bottle clean and sanitary, the milk bottle top with rubber tubing run around the inside is one that should appeal to those of us who prefer their milk sanitary. It makes the bottle absolutely tight, and avoids the accumulation of dirt in inaccessible corners, since it can be removed for perfect sterilization.

**No longer is the scrubber obliged to get down on the knees or wring the mop with the bare hands when using this improved mop**

## Taking the Scrubber Off Her Knees

EVIDENTLY the inventor of the new mop depicted in the accompanying illustration became tired of having scrubbing done on the knees, and wringing the mop out by hand wringing. For with this mop the worker, through the use of an arrangement of gears and suitable handle, can wring the mop by turning a crank handle and scrub and dry the floor while standing in an upright position. The knitted mop head used is all in one piece and is easily removable when a new drying medium is needed. Once the mopping surface is placed against the floor, it lies perfectly flat and does not require a stooping position of the worker in order to secure this result.

## New Cleaning Tool for Housekeepers

BEFORE this recently-patented cleaning device for brushes was available, either the hand was used to remove lint and hair from the revolving brushes in carpet sweepers and vacuum cleaners, or a metal comb. The work was highly disagreeable, to say the least. The present cleaner is like a cat's claw. It is strongly made and will remove the strongest accumulation of strings, hairs, etc. It is said to do its work without pulling out the bristles in the brushes.

**The rubber tubing in this cap renders it sanitary**

## Recent Patent Decisions

**Defense on Intimidation.**—This is an action for damages to plaintiff in his business of selling a varnish by reason of defendant's unfair competition. The plaintiff had manufactured and sold a varnish called "Varnish No. 25." It was manufactured by a secret process, was a varnish in its nature, composed of ingredients in such a way that it was free-flowing and reasonably quick-drying. It was commonly used to inject into tires of a bicycle to fill pores or small punctures in the rubber bicycle tires, and was manufactured by the plaintiff for that purpose.

The defendant by assignment became the owner of a combination patent issued to Chas. E. Duryea. This patent covered the use of a free-flowing gummy fluid within a pneumatic tire for sealing punctures. At the time of the purchase of the patent by the defendant, there were several compounds similar to that of the plaintiff being manufactured and sold in different parts of the country, and the defendant immediately began an active campaign to force the discontinuance of the manufacture and sale of them, claiming that its patent granted to it the exclusive right to use any liquid or powder inside a hollow pneumatic tire for the purpose of sealing punctures.

The failure of defendant, manufacturer of a fluid to seal punctures in pneumatic tires, to sue plaintiff, manufacturer of a like fluid, for infringement of patent, and defendant's publication of letters, circulars, and envelopes, which he used to threaten plaintiff's customers with suit if they continued to use plaintiff's fluid or varnish, held to be consistent with the good faith of defendant in the exercise of an intent to protect its business, thereby not warranting a jury in finding any malevolent motive to harm plaintiff in the destruction of his business rather than in legitimate endeavor to protect patent.—*Edwards v. Buff. Spec. Co. Supreme Judicial Court of Mass.*

**This claw-like device enables one to clean the vacuum cleaner brush with ease**

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farm Implements, Etc.*

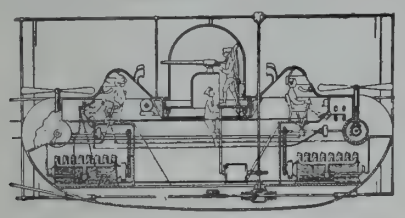
## Pertaining to Apparel

NECKTIE.—A. M. BAKERMAN, 413 E. 138th St., New York, N. Y. The object of this invention is to provide a self-tied neck tie of the four-in-hand model, manufactured to resemble a tie as usually worn and tied on and around collars. A feature is to provide a tie in which all the parts are so arranged that the tie may be quickly adjusted into place and securely held in service position.

SWEATBAND FOR HATS.—J. C. PETERSON, 34 N. Gifford St., Elgin, Ill. The invention has for its object to provide a sweatband which can be adjusted to fit any ordinary hat, which will allow of circulation of air around the head, and which can be removed and replaced as desired. A feature is to provide a band of conical form conforming with the shape of the head and not with the shape of the hat as is customary.

## Pertaining to Aviation

FLYING CRUISER.—N. G. Cox, Livengood, Territory of Alaska. The invention relates more particularly to such flying machines as are suitable for use at times as vessels capable of floating in water, and adapted for service in warfare. Among the objects is to provide



A VERTICAL SECTION SHOWING THE VARIOUS MECHANISMS

extensible wings so arranged that they may be increased or diminished, or folded, and thus rendered inactive, and to provide afcilities rendering the vessel self-supporting, and to provide propellers so arranged that the axes thereof may be shifted to different angles relative to the hull of the vessel.

## Electrical Devices

INDICATOR.—J. W. CARTER, JR., 5th and Pine Sts., Abilene, Texas. The object of the invention is to provide a device especially adapted for use on storage batteries, to indicate the date of the last watering, and that of the next, both in winter and in summer, and to indicate the date of charging, and whether full or partly charged, and so arranged that it may be locked to prevent accidental displacement or tampering.

ELECTROPLATING APPARATUS. — W. DIETZEL, Merrick, N. Y. The object of the invention is to provide a plating barrel whereby the operation is reduced to a minimum. Another object is to provide a barrel which may be charged from a number of different points without the adjustment of any parts and may be discharged by merely a reverse rotation. A further object is to provide a device so constructed as to hasten the plating operation.

## Of Interest to Farmers

MARKER FOR PLANTERS.—O. H. KOHLHAAS, Calumet, Mich. The invention aims to provide a device particularly adapted to be used in connection with a planter, such as a corn planter, the marker being adapted to be operated substantially simultaneously with the seed dropping mechanism so as to subsequently indicate the location of the various hills. A further object is to provide an extremely simple mechanism which might be applied to any type of planter.

## Of General Interest

FOUNTAIN PEN CLEANER.—C. W. GARVER c/o Western Union Telegraph Co., Ashland, Ohio. The invention has for its object the provision of a simple, inexpensive and efficient device of the character specified, in the form of a tubular casing of suitable material, adapted to receive in one end the pen supporting portion of a fountain pen, and to engage within the other the outlet of a water faucet.

DEVICE FOR TEACHING PENMANSHIP.—J. D. W. WILLIAMS, Tabor, N. C. The purpose of the invention is the provision of a simple and efficient device of the character specified which will exercise and train the muscles of the hand and arm in the formation of ovals. It is well known that the oval constitutes the fundamental figure in penmanship, with the pupil's muscles trained to accurately form such a figure a great stride has been made to writing legibly and rapidly.

LAWN EDGE TRIMMING GAGE.—J. LEES, 1705 W. Broad St., Bethlehem, Pa. The object of the invention is to provide a gage bar of metal construction, which can be pinned along the edge of a walk so that a cutting implement can be used in connection therewith in trimming off the turf in a smooth and even manner. A further object is to provide a gage which is adjustable so that at the edges of various widths can be trimmed and a cutting implement to be used in connection therewith.

WEATHER STRIP.—O. S. BRANHAM, 323 No. Virginia Ave., Roswell, N. M. The invention has for its object to provide a strip of the character specified, mounted to move laterally and longitudinally of a door and controlled by the opening and closing of the door for movement in such lateral and longitudinal directions, to tightly seal the space between the bottom of the door, and the sill when the door is closed.

LAMP BRACKET.—R. F. FERGUSON, 550 Waterloo St., Detroit, Mich. The invention has for its object to provide a simple and inexpensive bracket of the character specified, wherein a maximum of adjustment is permitted. In operation the lamp is arranged on an angle plate, the angle of which may be adjusted to vary the beam of light and after the parts are adjusted they may be securely locked.

FLOWER HOLDER.—MARY G. TILNEY, 935 Government St., Mobile, Ala. The invention provides a trough or water container with a wire mesh cover adapted to be sunk into the ground over a grave. Cut flowers are placed on the grave with their stems projecting through the mesh into the water in the container and are thereby kept from wilting.

CARD APPLIANCE.—H. MAIER, 1148 Hancock St., Brooklyn, N. Y. In order to assist cripples in the playing of card games the inventor has provided a device with which a one-armed man may shuffle and deal cards with the same facility as that of a normal man. The device is of very simple and inexpensive construction.

CLOTHESLINE HOOK.—H. C. LAFFERTY, 9528 116th St., Richmond Hill, N. Y. An object of this invention is to provide a clothesline hook which has a main supporting forked arm adapted to secure a clothesline thereto without the tying of knots. The device is provided with one or more auxiliary hooks to which several runs of clothesline may be attached.

FASTENING DEVICE FOR EAR ORNAMENTS.—H. T. MOLER, 1720 8th Ave. No. Birmingham, Ala. The invention is an improvement in fasteners for ear ornaments, and has for its object to provide a simple and efficient device for securing an ornament firmly in place on the ear in such a manner that it will cause no inconvenience. The device will follow the natural curve of the ear and may be easily detached when desired.

ADVERTISING DEVICE.—L. D. WHEATLEY, 564 E. Oak St., Portland, Ore. The device will simulate perpetual motion. A wheel is mounted between a pair of set screws carried by hollow standards. The point of one of the set screws is revolved by flexible shaft connection with a motor in the base of the mechanism. The other set screw is connected with the motor in such a way that when it is screwed back to remove the wheel the motor is stopped.

LIFTING DEVICE OF GRAPPLE.—M. CLOGSTON, 915 Harrison Ave., Terre Haute, Ind. The present invention provides a grappling means for effectively engaging with boxes, crates, cases and the like, which will be readily releasable when pressure is released so as to avoid the necessity of special tools for knocking the grapple free. The engaging elements may be readily detached for sharpening or substitution.

PROCESS OF PREVENTING THE INNER WALLS OF RUBBER HOSE FROM STICKING DURING MANUFACTURE.—F. C. MORSE, Canton, Ohio. A process is herein provided by which the uncured core or tube after being formed and before being braded may be economically treated so that it may be left for any length of time without any danger of the inner walls of the tube sticking together, should the tube become compressed for any reason.

FEED BOX.—R. R. STICKLER, R.F.D. No. 1, Wausau, Wisc. The invention provides an improved feed box for feeding cattle, which is attached to the stanchion by a system of levers which permit of swinging the feed box out of reach of the cow when not in use and of swinging it into position in front of the cow when the cow is to be fed.

GEOMETRIC FIGURE.—E. T. MILLER, San Antonio, Tex. A new geometric figure is provided for plotting and delineating a pattern for a covering for balls. The coverings are so formed as to require a minumum length of closure, thus lessening the amount of sewing necessary for the complete closure of the covering over the ball.

TOOTHPICK DISPENSING DEVICE.—C. H. BENNETT, 107 Chapel St., Mount Morris, N. Y. An object of the invention is to provide a sanitary device which will prevent the handling of the toothpicks and present one at each operation. A further object is to provide means for operating a cylindrical toothpick receptacle having a gripper thereon which is movable into the receptacle to grip a toothpick and convey the same to a position outside of the receptacle at each operation of the device.

ARTIFICIAL LIMB LOCK.—L. E. HULLINGER, 255 Bergen St., Brooklyn, N. Y. An object of the invention is to provide a lock for an artificial arm, by means of which the lower arm may be locked in any number of positions with respect to the upper arm. The invention aims to provide such a device by means of which the wearer may be capable of performing certain functions in a far more simple manner than has been the practice heretofore.

COAT HANGER.—J. L. WEBER, 407 S. Clinton St., Chicago, Ill. Among the objects of the invention is to provide a coat hanger which can be readily adjusted to be suitable for coats of different sizes, which can be folded to permit of its being carried in a pocket and which is simple and durable in construction, light in weight and can be manufactured cheaply.

FLEXIBLE CONNECTION.—R. STAR, 253 Bergen St., Brooklyn, N. Y. The invention relates to hose pipe connections. Among the principal objects are to avoid breaking extensible members forming flexible connections between relatively rigid devices, to provide a tabular member freely extensible without danger of rupture or damage to the structure, and to simplify and reduce the cost of manufacture of the connection.

CONDIMENT HOLDER.—P. P. DEAGUIAR, 156 Water St., New York, N. Y. The invention relates more particularly to salt shakers, an object being the protection of the salt from moisture so that it will not become lumpy or moist and can be readily shaken from the holder. A further object is to provide a holder which will be entirely sanitary, comparatively cheap to manufacture, and neat and attractive in appearance.

FOLDING CAMP BERTH.—W. F. MOODY, 6 Boston Bldg., Denver, Colo. The object of this inveition is to provide a knock-down structure which can be packed in relatively small space and which can be quickly assembled to form a portable double-deck berth providing four cots or beds in a single unit, and which is capable of assemblage of units in any desired number.

CARRIER FOR EXPLOSIVES.—C. A. COTTLE, 25 Church St., Edwardsville, Pa. The object of the invention is to provide a carrier adapted to receive a number of sticks of explosive. The device comprises a cylindrical casing including a body closed at one end and open at the other, a cover telescopically engaging over the open end, staples carried by the body to receive a strap handle, and a hasp engaging one of the staples to provide for a padlock or fastening at the opening end.

TORPEDO TRAP.—V. H. MASTERS and M. G. SHOOP, 315 N. French Ave., Sioux Falls, So. Dak. The invention has for its object to provide a trap wherein upper and lower sections, the free end of the lower section being buoyed to cause it to rise to the surface when unrestrained and being normally held below the surface by a counterweight, the sections supporting between them a net for engagement by the torpedo, the net being connected to mechanism for releasing the counterweight when the net is struck to cause the trap to lift the propeller of the torpedo out of the water.

AUTOMATICALLY OPERATED SUPPORT.—S. E. SUDBURY, 703 E. 6th St., S., Salt Lake City, Utah. The invention relates more particularly to an automatically operated support for use in connection with furniture and cabinet work. An object is to provide a pivoted support having a slot for the passage of a pin, the pivoted and slotted support including a switch head having an automatically operating switch for controlling the movement of the pin in closing a lid or similar device.

ADVERTISING ATTACHMENT FOR SCALES.—A. N. FUNJ, c/o Auto Advt. Weighing Machine Co., Houston, Texas. The invention has for its object to provide an attachment of the character specified, wherein a series of display members are provided, mounted to be moved into different positions, to bring different matter into display position and controlled to movement by the stepping onto the weighing platform of the person to be weighed.

HAIR FRINGE.—M. MULLER, address Wm. Kaufman, 1482 Broadway, New York, N. Y. The object of this invention is to provide a hair fringe adapted to be worn over the user's hair at the back of the head to provide a bobtail effect without requiring bobbing of the natural hair. Among the objects is to permit of quickly and securely fastening the hair fringe in position on the head or removing it when desired.

ORNAMENTAL ROPE.—C. A. REED, Williamsport, Pa. The invention relates to fringed ropes or strings adapted to be used for ornamental purposes, the object being to provide a rope of this character of simple and efficient construction. The several strips comprising the rope may be of variegated colors so that an ornamental effect is produced.

PENCIL.—W. K. HOLMES, 409 Pearl St., Brooklyn, N. Y. This invention relates to a pencil in which the lead is projected from a barrel by relative rotation of the pencil parts. A feature of the invention is that while the lead is projected by the relative rotation, it is not retracted thereby, but is provided with a yielding holder and upon the withdrawal of the projecting parts the lead must be pushed in against the pressure of the yielding lead holding means.

SILL CONSTRUCTION.—F. N. MARVICK, 608 W. 5th Ave., Pine Bluff, Ark. The invention has for its object to provide a construction of the character specified wherein the heavy wooden sill generally used is replaced by a plurality of pieces of relatively small cross sections, thus permitting heart pieces to be used, and a perfect insulation against dampness provided.

COMBINATION CLOSET SEAT AND BIDET.—DE FOREST L. RATHBONE, Box 1020, Jacksonville, Fla. The object of the invention is to provide a device capable of use in the ordinary manner as a seat and having a bidet or douch fixture in connection therewith, connected with the water supply and normally in inoperative position, and concealed by the seat but capable of being brought into operative position when desired.

SHOE HEEL.—E. S. HELWITZ, 1443 E. 9th St., Brooklyn, N. Y. The object of the invention is to construct an elastic pad for "French" heels in a very durable and economical form, and to make it attachable to the leather heel without the use of screws, tacks or other devices, and so constructed that the pad may be removed or attached readily and will not become a necessarily unseparable part of the shoe.

CHART HOLDER.—C. W. BABCOCK, 221 Harvard St., Brookline, Mass. The invention relates to means for supporting charts and map holders to be used aboard ships. The object is to provide a holder which will be easily adjusted to fit various lengths of charts or maps, and to support and hold them in taut condition, a chart holder frame being provided to expose the charts to view during navigation.

SCREENING OR FILTERING APPARATUS.—H. D. WELLS, 35½ Grant Ave., Glens Falls, N. Y. The object is to provide a screening or filtering apparatus designed for use as a pulp thickener or as a pulp washer or as a water filter. Another object is to

## RECENTLY PATENTED INVENTIONS

provide an apparatus which has a large capacity, requires little or no labor attendants, avoids loss of pulp and reduces cost of wear and labor to a minimum.

COMBINATION HEEL.—F. J. McEwan, 531 N. Lawler Ave., Chicago, Ill. Among the objects of the invention is to provide a combination heel which has greater resiliency and durability than a solid rubber heel, which may be adapted to shoes of various sizes, and which will not slip on a wet surface, or be noiseless in a manner objectionable to many persons.

HYDRAULIC JOINT CARTRIDGE.—E. Rimailho, 98 Rue de la Victoire, Paris, France. The present invention has for its object an arrangement of removable joints, the organization of which is designed in view of insuring the easy replacing of the same whatever may be its apparent complexity. For this purpose all the organs of the removable joint are assembled upon a same mounting which is previously located into a mounting tube in which the joint is definitely adjusted for the use to which it is intended.

ROAD TRAIN.—E. Rimailho, 98 Rue de la Victoire, Paris, France. This invention relates to a road train formed by an automobile set comprising a transporting vehicle, the load transported by which produces the energy necessary for the transporting vehicle The set may be applied to the transport of all burdens, especially of vehicles, and in particular of ammunition and ordnance vehicles in the form of caterpillars.

PRINTING MACHINE HAVING AN OSCILLATING IMPRESSION CYLINDER. — C. Winkler, Berne, Switzerland. The invention relates to a system of tapes for holding the sheets during both the printing operation and the subsequent delivery of the sheets to the leading out device. By this invention the back edge of the sheet during the backward oscillation of the impression cylinder is prevented from leaving the cylinder before the proper time, thus, a good delivery of the sheet is assured.

COLLAPSIBLE BOX.—L. S. Lundy, Niagara Falls, Ontario, Canada. The invention relates to boxes made of cardboard, corrugated paper board, or suitable material. The object is to produce a collapsible box so constructed that it may be opened to remove its contents without destroying its usefulness, as a sealed container, and whereby it may be used a plurality of times, thus effecting a considerable saving.

REFLEX FOCAL PLANE CAMERA.—M. B. Boyce, 2 5th Ave., Haverhill, Mass. This invention relates to cameras of the automatic reflex focal plane type. A specific object is the provision of a camera having a moving picture lens and an adjusted moving picture shutter in combination with means for releasing the shutter, which latter is motor driven by a spring, the tension of which can be adjusted as desired. The camera is designed for moving picture films which will permit of enlargements with highly satisfactory results.

CANNING FOOD PRODUCTS.—J. F. Tronconi, Calle Maipu 671, Buenos Aires, Argentina. The invention relates to the method of canning food products, including meat as a main ingredient. The process consists in providing a can or container with a lining of gut in its interior, in such a way that after introducing the product, the latter will be entirely wrapped in the lining of gut, thereby preventing a direct contact with the can and providing at the same time a means for extracting the contents as an entirely wrapped block.

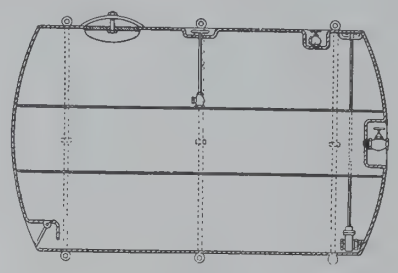
SHOE FASTENER.—P. Ferris, address E. A. Ferris, Westwood, Cal. This invention has for its object to provide a shoe with a series of independently operated fastening devices which can be conveniently attached or replaced when worn or broken and which will permit the shoe to be secured around the ankle and foot to conform to the shape thereof by reason of the fact that the individual fastenings can be adjusted so that they may be of varying lengths at different points on the shoe.

POST AND SIDE BAR OF BEDS, FURNITURE AND THE LIKE.—B. S. Gamble, West Perth, West Australia, Australia. The purpose of the invention is to form a joint or connection between the upright or leg and the side bar of a bedstead or other article of furniture or fitting in connection with like purposes. The invention is in the form of a steel bracket and plates and may be applied to articles of various material although especially applicable to wooden bedsteads and other wooden furniture.

DRIER.—G. L. Spencer, Riverbank Court, Cambridge, Mass. The invention aims to provide a device by which an operator shall be enabled rapidly to determine the amount of moisture in laboratory tests of various substances, particularly raw sugar. A further object is the provision of an oven which will enable the analyst to make rapid control tests in factory work, and in laboratories generally.

CANDY WRAPPER.—W. S. Stoner, 90 West St., New York, N. Y. The object of the invention is to provide a wrapper which will not only act as a protection for the candy but at the same time so construct the same as to offer unusual inducements to the purchaser in that aside from purchasing the candy they are in reality purchasing, a paper doll which may be used as a source of amusement after the candy has been removed the wrapper still retaining its doll characteristics.

SALVAGING APPARATUS.—C. Sanger Bay St. Louis, Miss. The invention relates to the salvaging of sunken vessels and the like. The prime object is to provide a tank capable of being submerged by filling the same with



A LONGITUDINAL SECTIONAL VIEW OF THE TANK

water which is subsequently discharged from the tank to render it buoyant. A further object is to so construct the tank that it contains suitable means for discharging the water and means for controlling the discharge.

THREAD CUTTER.—Helen. S. Carson, Hyde Park Hotel, Chicago, Ill. An object of this invention is to provide a thread cutter attachable to a sewing thimble, which is so small that it will in no way interfere with the functions of the thimble, and still have the cutting edges so effectively arranged that the thread can be readily caught and cut by a stroke to the right or left.

SYRINGE.—O. O. R. Schwidetzky, Hasbrouck Heights, N. J. Among the objects of the invention is to provide a syringe consisting of a glass barrel and a rubber bulb, arranged to permit of securely fastening the bulb to the barrel and to prevent the liquid drawn into the barrel from flowing into the bulb on inclining the syringe with the nozzle upward, the wall of the barrel having a minute air passage preventing the passage of the liquid.

ANIMAL TRAP.—E. E. Rodgers, A. W. Wenger and C. M. Rodgers, c/o A. W. Wenger, Bitem Bate Co., Warsaw, Ind. Among the objects of the invention are to provide a simple form of animal trap having one or more openings, which may be easily set without the danger of accidental release and the catching of the fingers, yet may be readily sprung, thereby insuring the successful operation of the device. The bait is so placed that it is independent of the trigger or releaser.

VENDING DEVICE.—A. B. Simon, 3636 Douglas Blvd., Chicago, Ill. An object of the invention is to provide a vending device in which packages or containers of different sizes may be used and in which an economy of space is effected so that the capacity of a vending machine of good dimensions is materially increased over the ordinary vending device. To prevent tampering the device may be locked by a concealed lock.

THREAD CUTTER.—L. G. Fritz and A. A. Herzberger, 385 E. Perry St., Tiffin, Ohio. This invention has for its object to provide a device preferably mounted upon a finger ring and having means for cutting thread, cord or the like, so held that there is no possibility of injury to the wearer, and having means for guiding the thread into the cutter.

FOUNTAIN PEN FILLING DEVICE.—A. T. Cross, Box 352, Wickford, R. I. The invention relates generally to fluid dispensing apparatus and more particularly to a simple form of hand-controlled dispensing arrangement to be applied to bottles. While the invention is capable of more or less general application, it is especially designed for the filling of fountain pens; it permits of manipulation with but one hand, while the other hand holds the fountain pen or other device to be filled.

STEMLESS SELF-CLOSING VALVE FOR HIGH PRESSURE TANKS.—E. E. Garland, 7 Anderson Ave., Port Richmond, S. I., N. Y. The particular object of the invention is to provide a stemless automatically self-closing valve for use in connection with high pressure gas tanks. Another object is to provide a valve which is of simple and rugged construction having few parts, and these conveniently arranged to permit of the removal or replacement of the safety means without interfering with the adjustment or setting of the other valve parts.

CRATE.—W. D. Woodruff, Belton, Texas. An object of the invention is to provide a crate especially adapted for carrying fruit, as for instance, peaches, tomatoes, berries and the like and for retaining said fruit in perfect condition without bruising or mashing, and may be stacked one upon the other without danger of collapsing.

METHOD AND APPARATUS FOR MOLDING OR CASTING ARTICLES OR INGOTS FROM MOLTEN METAL.—E. C. Wills, Box 163, Rahway, N. J. The invention has for its object to provide a method and apparatus for subjecting the cast articles while in a plastic state and in the mold to heavy pressure, for thoroughly compressing the molten metal in the mold to eliminate defects due to unequal expansion or contraction or from any other cause.

STILT.—R. J. Lynch, 84 Hunter St., Tamaqua, Pa. The invention relates to adjustable stilts and has particular reference to a step or foot support stamped or cut from a piece of sheet metal and adapted to be associated with a standard in such manner as to permit the ready vertical adjustment thereon and its positive securement in its adjusted position.

METHOD AND APPARATUS FOR SINKING PILING.—E. F. Estes, 1315 E. St., Lincoln, Neb. The invention contemplates a movable device for use in the hydraulic sinking of piling, and in the course of which operation the ries to be overcome a side pressure of the surrounding earth against the sides of the piling, that may be likened in part to that occurring in the excavation of a well when a cave-in is threatened.

PROCESS OF MAKING MONOLITHIC PAVEMENTS. — A. J. Parrish, Paris, Ill. The purpose of the invention is to provide a monolithic construction in which a base of concrete is provided, the bricks being set in the plastic concrete and pressed and then the spaces between the bricks filled with cement filler so that when the cement and concrete harden the whole forms a rigid structure not liable to disintegrate as in the case of a construction with sand cushions.

POLISHING WHEEL.—R. W. Putnam, c/o Cooley Wright Mfg. Co., Waterbury, Vt. The invention relates to wheels commonly known as ironing wheels, an object being to provide an arrangement of scroll on the under surface of the wheel which prevents the accumulation of abrasive or other material used for grinding or polishing the surface of stone, always tending to move such abrasive material toward the center of the wheel.

FIREARM.—O. F. Mossberg, 273 State St., New Haven, Conn. The general object of the invention is to provide a small firearm or pistol, and more porticularly a firearm in which the barrel with plural bores is stationary in the firing operation while the firing pin is revolved and its firing member, which is off the center of the pin, is caused to contact with the successive cartridges.

MOVING PICTURE THEATER.—E. W. Van Fleet, 622 Con. Realty Bldg., Los Angeles, Cal. An object of the invention is to eliminate the seats in proximity to the screen, which are undesirable on account of distortion and disorder induced in the optic nerve. The arrangement does not diminish the seating capacity of the house; the chairs are separated by a low partition placed transversely between two screens, one at each end of the theater, the patrons being seated facing the screen farthest from them, and therefore not less than half-way back in the house from the screen which they face.

COTTON GIN.—O. C. McBride, 215 E. Pierce St., Mangum, Okla. An important object of the invention is to provie a lint flue with means adapted to automatically operate to discharge the cotton from the lint flue when the pressure therein becomes excessive by reason of the cotton clogging in the lint flue due to the improper action of the condenser or to other causes. The device will not necessitate any special construction of gin or condenser.

COMBINATION TALKING AND MOVING PICTURE MCHINE.—P. T. L. Champeix, Menton, France. The invention relates to apparatus for presenting animated pictures formed by sections of an illustrated band or bands. An object is to provide a simple, efficient and inexpensive apparatus which can be easily synchronized with a phonograph through the medium of mechanical means which control the movement of the sections of the band forming the picture.

EXCAVATOR.—J. J. Warren, Genl. Delivery, Seattle, Wash. The object of the invention is to provide a simple and efficient excavating machine by means of which tunnels, trenches, ditches and the like may be rapidly dug with small expense of power, and the minimum of operators or workmen. A further object is to provide an excavator which can be easily handled, which is self-driven, and in which a single prime mover is used both for the operation of the excavator and its travel and maneuvering.

RECORD FILING CABINET.—R. McCart, Jr., 221 Mills Bldg., El Paso, Texas. This invention aims to provide a filing cabinet which at all times will present all of the records contained therein in plain view and in such manner that the title, which may be pasted or otherwise applied to the individual record container, may be read without stooping. A further object is to provide a filing device which will accommodate records of different sizes.

LABEL.—R. A. Van Clief, 190 Summer St., Buffalo, N. Y. A particular aim of the invention is to provide a poison label for bottles or other containers, the object being to provide a label constructed with luminous letters which can be readily distinguished at night, and by this means obviate accidents, such as are caused by persons in the dark. The label can be attached to any bottle, and is so constructed that the luminous paint is entirely protected from the air and will retain its luminous qualities.

ADJUSTABLE COMPASS DIAL.—H. T. Zeiner-Henriksen, Framnaesveien 12, Christiania, Norway. The invention has for its object an adjustable compass dial comprising two transparent disks rotably connected with each other, one of the disks being provided with a complete set of points, while the other disk is provided with a rectangular cross adapted to indicate the four main directions of the compass.

GUN CARRIAGE.—E. Rimailho, 12 Rue de la Rochefoucauld, Paris, France. The inventor has been granted two patents of a similar nature, the inventions having special reference to a gun carriage forming a complete artillery unit so constructed as to permit of traveling over all sorts of ground owing to its large bearing surface on the soil. It is particularly valuable on light or wet soil. The gun carriage consists essentialy of a chassis, having supports for the trunnions of the cradle of the gun and provided with rollers which roll over the chains actuated by driving wheels moved by an electric motor located on the carriage itself and fed by electric current furnished by a dynamo driven by a motor also located on the carriage.

READING GLASS HOLDER.—J. T. Spradling, White Plains, N. Y. The primary object of the invention is to provide a reading glass holder for use in connection with typesetting machines for the purpose of more clearly bringing out the manuscript of the copy from which the operator is working. A further object is to construct the device in such a manner that the glass is movable with respect to the manuscript copy, and is automatically returned to its starting point.

AGITATING DEVICE.—P. G. Campbell, Monolith, Cal. The primary object of the invention is to provide an agitating device to be used as a kicthen utensil for sifting flour and the like, by which better results may be realized in preparing flour for bread-making, particularly when the device is employed for mixing baking powder with the flour.

### Hardware and Tools

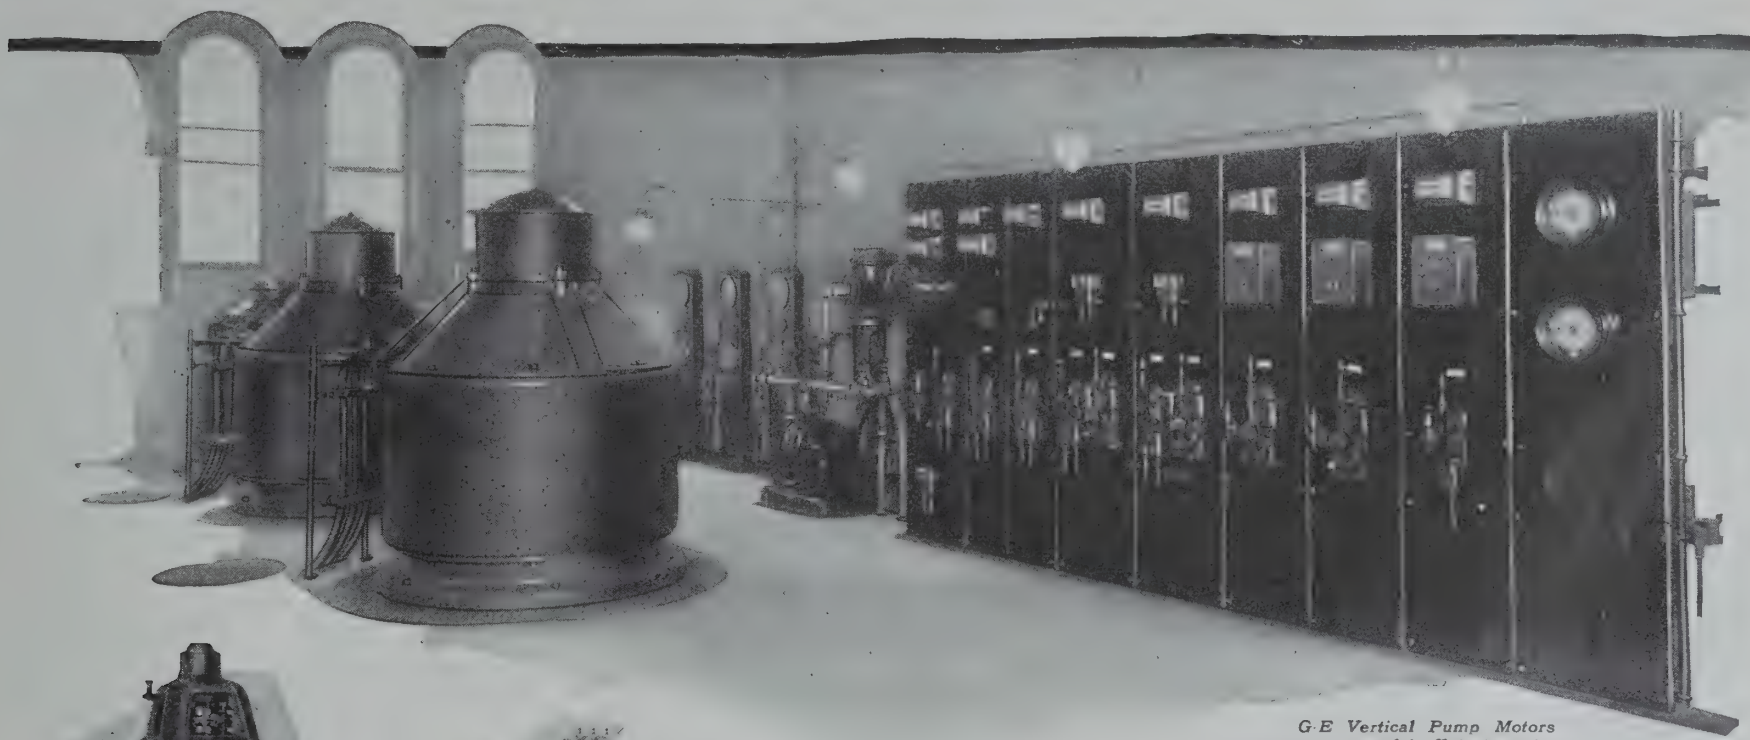
INSULATED TOOL.—J. A. Weaver, 238 So. Patterson Park Ave., Baltimore, Md. This tool is provided with a movable insulating sleeve carried by the contacting portion or blade of the tool which completely covers the blade in a manner to prevent injury to the operator, while at the same time it enables the tool to be properly used in fulfilling its function.

PUNCHING SHEARS.—E. E. Cornell, 2714 Rutger St., St. Louis, Mo. The object of Mr. Cornell's invention is to provide a simple economical and effective hand-operated implement for slotting paper, card board, sheet metal and the like. The implement has a shearing action and is capable of ready adjustment in respect to the length of the slot to be cut.

CASEMENT ADJUSTER.—C. J. Hagstrom, Maple Ave., Glen Cove, N. Y. This casement adjuster is readily adaptable to any casement

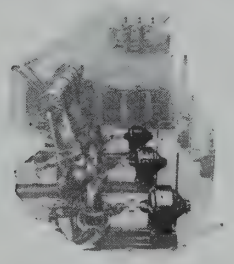
*(Continued on page 436)*

*The margin of profit in many industries largely depends upon the efficiency, dependability, and low upkeep cost of machinery used*

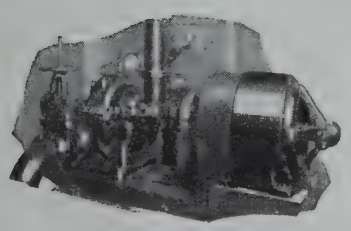


*G-E Vertical Pump Motors give powerful, efficient service in this water pumping station.*

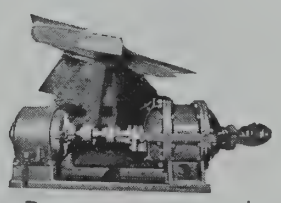
*Vertical Motor direct drive for centrifugals or pumps.*



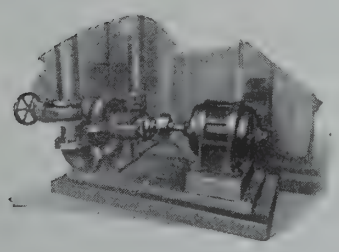
*Motors direct connected to centrifugal pump—6000 gallons of water per minute.*



*Protect your industry with motor-driven fire pumps.*



*Dependable operation of motor-driven pump under severe conditions in mining.*



*Motor driving battery supply pump in sugar mill.*

*Widespread developments in irrigation through use of motor-driven pumps.*

## *Electrically driven pumps raise the margin*

PUMPING costs receive careful scrutiny in the economical management of many industrial properties. Consideration of the most satisfactory solution of the varied problems involved leads to electric drive in which G-E Motors and attending equipment are specified.

Pumping stations, mills, mines, textile factories, chemical plants, irrigation developments—all have presented diversified requirements in adopting electric pump drive.

The capacity of the pump manufacturer to produce particularized installations has been instituted by the specialized efforts of G-E engineers, co-operating with him.

Securing this equipment and co-operative service of the General Electric Company through your manufacturer is to combine the greatest efficiency and dependability in the application of electric power to your pumps.

General Electric Company

## RECENTLY PATENTED INVENTIONS

(*Continued from page 434*)

window, door, or other swinging object and is arranged to hold the window or door frictionally, but substantially, at any desired adjustment with respect to the wall.

EDGE TRIMMER.—W. H. BROWNING, 16 Cooper Sq., New York, N. Y. The invention relates to garden tools; an object is to provide a device which can be operated along the edge of a walk or around the edge of a flower bed or the like to cut the grass which hangs over or is pressed down by the mower in cutting the lawn.

LOCKING DEVICE.—G. W. BURTON, 1471 Broad St., Providence, R. I. The invention has reference more particularly to a locking device which embodies some of the characteristics of a nut lock, although its salient features are in no way represented by a nut lock except that the device is intended to be associated with a bolt or spindle which is threaded at one end, and in which such threaded end is received by the lock device, with the device confining and locking a structure on the bolt or spindle.

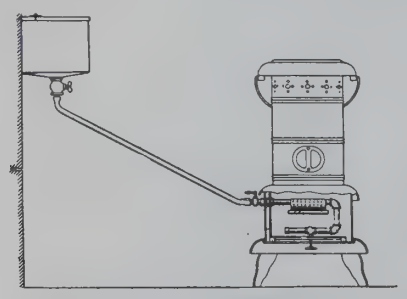
EXPANSION REAMER.—S. H. HUMPHREY and F. H. KORFF, 48 Academy St., Poughkeepsie, N. Y. The invention relates more specifically to means for permitting the convenient and ready adjustment of reamer blades. One of the objects is to provide an adjusting means which is inexpensive to manufacture, simple and rugged in construction and so constructed and arranged as to be readily adjusted to obtain a definite adjustment of the cutting edges of the tool.

MICROMETER GAGE.—T. SHAW, Woonsocket, R. I. This invention relates to measuring instruments, and has for its object the provision of a micrometer gage embodying in its construction indicating wheels moved by rotary movement of the handle and carrying indicia visible through sight openings, these indicia indicating the dimension of an object being measured directly and without the troublesome use of a vernier scale.

ADJUSTABLE CUTTER.—F. H. KORFF and S. H. HUMPHREY, 48 Academy St., Poughkeepsie, N. Y. Among the objects of this invention is to provide an adjustable cutter which is simple and strong in construction, inexpensive to manufacture and which is so constructed as to be conveniently adjusted to different predetermined sizes. A further object is to provide a micrometer adjustable cutter having indicating marks thereon so that the effective cutting edges of the tool may be adjusted to a predetermined size.

### Heating and Lighting

OIL BURNING HEATER.—D. SEINIGER, c/o Standard Kertogas Co., Middletown, N. Y. The object of the invention is the vaporizing of kerosene into gas, the device being constructed of materials which obtain complete combustion. Its purpose being the replacement of burners,



AN ELEVATION WITH HEATER BODY PARTLY BROKEN AWAY, AND IN SECTION

using oil, gasoline, distillate or gas, for producing heat, power or steam, and its application is to heater bodies, such as room heaters, water heaters, cooking ranges, small hot water boilers and machines requiring gas or steam.

DEVICE FOR CONSERVING FUEL.—W. O. WOOD, Riverside, R. I. The invention relates to a device for employing the heat contained in the flue gases of stoves, furnaces and boilers. An object is to utilize air heated by the flue gases for heating purposes. A further object is to use the heat contained in the flue gases to pre-heat air supplied to the grate of the heating unit.

INDEPENDENTLY DETACHABLE UNDERSHADE FOR LIGHT STANDARDS.—M. Y. SUGIMURA, 32 Union Sq., New York, N. Y. An object of the invention is to provide an under lamp shade which serves as an indirect light reflector and also softens the direct downward glare from the source of illumination positioned above, and to permit such a shade to be independently removed without disturbing the assembly of the lighting fixtures.

HEATING MEANS.—W. W. LILLARD, c/o E. J. King, 141 Howard Terrace, Leonard, N. J. The object of the invention is to provide a heating means for heating monolithic structures such as street gutters and sidewalks, to melt the snow, and thus rendering it serviceable for heating floors of factories, schools or other buildings. The heatig medium can also be used in incubators and brooders, and can also form individual portabe heaters for use as bed warmers, foot warmers and the like.

OIL BURNER.—A. T. TIMOSCI, 668 Willis Ave., N. E., San Jose, Cal. This invention relates to oil burners, and has for its object to provide a small and efficient burner of the character specified, wherein the oil is sprayed on to a heated plate by means of fluid under pressure acting in the manner of an injector.

### Machines and Mechanical Devices

CUTTER HEAD.—F. P. MILLER, c/o McCroskey Reamer Co., Meadville, Pa. The invention relates to cutter heads such as are used in milling machines; its object is to provide cutter heads whereby the cutting tool is firmly drawn into position in its seat and is securely fastened therein without the use of set screws or similar devices. Another object is to permit of quickly fastening the cutter in place and to allow of removing it whenever desirable.

PIPE PULLER.—S. ROBICHAUX and C. PAGGI, 3303 Montrose Blvd., Houston, Texas. This invention provides an improvement in pipe pullers and has for its object the provision of mechanism for use in connection with the pulling mechanism for pipe casings of wells of the character described in a previous patent (No. 1,280,850) granted to the same inventors. The present mechanism is used for gripping the pipe and threading or cutting the same as it is pulled.

MACHINE FOR BURNING IN BEARINGS AND LIMBERING UP MOTORS.—A. O. WHITE, High Point, N. C. The general object is to provide a machine for burning in bearings and limbering up motors and more particularly to an arrangement for rotating the crank shafts of automobile motors. A further object is the provision of an arrangement adapted alike to motor blocks removed from their supports, as well as to the crank shafts of automobiles complete and ready for operation.

SHEET GUIDE FOR FOLDING MACHINES.—E. SCHEICK, 17 Trinity Place, Arlington, N. J. The invention relates generally to a feeding device for folding machines and is particularly adapted for use in feeding relatively long and narrow strips of paper, to the folding rolls, on what is known as the Cleveland folding machine, but can be used in other machies employing a sheet feed mechanism and where an accurate fold is desired.

ROLLER BEARING AND METHOD OF MAKING THE SAME.—H. J. JONES, 72 Floyd St., Belleville, N. J. This invention relates to the construction of roller bearings as distinguished from ball bearings, and has particular reference to the form and method of making the rollers constituting the antifriction elements of such bearings. Among the specific objects is to provide a roller in which the grain or fiber of the metal extends as nearly as possible parallel to the direction of rolling action, whereby the likelihood of chipping, flaking, or crushing of the rollers will be reduced to a minimum.

TUMBLING APPARATUS FOR FURS.—B. & S. FRIEDMAN, 232 Keap St., Brooklyn, N. Y. The object is to provide a tumbling apparatus for softening furs or pelts, arranged to insure an intense tumbling action with a view to quickly soften a large number of furs simultaneously and without danger of injuring the furs. Another object is to permit the operator after the tumbling action is completed to quickly and efficiently separate the furs and the sawdust or other tumbling material used.

BOBBING AND SPINDLE CONNECTION.—C. NORDELL, Gilbertville, Mass. An object of the invention is to provide a bobbin holding mechanism which depends on centrifugal force to form a friction connection between the revolving shaft and the bobbin. A further object is to provide a device of the character stated which will be extremely simple in construction and durable in use.

MECHANICAL MOVEMENT.—G. MULLER, 103 Schley St., Glendale, L. I., N. Y. The invention relates to mechanism for converting reciprocating motion into intermittent rotary motion; its object is to provide a mechanical movement especially designed for intermittent feeding purposes and which is simple and durable. Another object is to reduce the wear of the working parts to a minimum and to insure proper functioning of the parts without danger of binding or sticking.

SUCTION CONTROLLING DEVICE.—L. J. DELLERT, 176 Russell St., Brooklyn, N. Y. This invention relates to grinding and polishing machines having a plurality of grinding or polishing wheels provided with dust receiving hoods connected by branch pipes with a main suction duct connected with a suction fan to produce suction and carry off the dust and other particles, arising by the operation, to protect the workmen against inhaling the particles.

CLOCK.—C. H. ANDERSON, address H. R. Kleinbach, c/o Title Guarantee Trust Co., Los Angeles, Cal. This invention has for an object to provide a construction wherein the time indicating means is arranged so that a number will indicate the hour, and an oscillating point the minutes. A further object is to provide means which is capable of being connected to ordinary clock mechanisms now in common use.

POST FOR SCALES.—G. G. and E. L. VOLAND, 48 Trinity Place, New Rochelle, N. Y. The invention has for its object to provide a post for scales, having means to indicate when the post is in true vertical position. As a means of determining the vertical position of the post a plumb is provided which is secured to the transverse member of the scale, it being possible to compare the position of the plumb relatively to marks on the base of the scale.

METHOD OF TREATING PEAT.—W. W. BLAIR, 141 Milk St., Boston, Mass. This inventor has been granted two patents of a similar nature which relate to a process for the treating of peat for fuel purposes. Among the objects of the inventions is to provide a machine for macerating and blocking the peat. The two processes of treatment consists of macerating the freshly dug peat and pressing the same into blocks, and compressing unmacerated peat into blocks, drying the blocks and then immersing the blocks in an oil bath to impregnate them with a fuel oil.

### Musical Devices

PLAYER PIANO ACTION.—W. J. WODRASKA, 1290 1st Ave., New York, N. Y. Among the objects of the invention is to provide a player piano action of the most compact and simple construction adapting it for cheap manufacture. Another object is to provide for each pneumatic or pair of vertically alined pneumatics a single and detachable valve block, the same providing for easy inspection or repair of any valve or associated parts without disturbing any of the other valve mechanisms. A further object is to provide valves so balanced as to be most responsive to the pneumatic operation.

DISK RECORD HOLDER.—G. E. FOSS and H. G. JENSEN, c/o G. E. Foss, 1638 N. Avers Ave., Chicago, Ill. The invention relates to holders for disk phonograph records. An object is to provide an inexpensive holder in which the records may be held compactly, means being provided for identifying any record and for moving it forwardly, whereby the record may be easily withdrawn. A further object is to provide a holder which is adjustable so that records of various sizes may be held.

RECORD CABINET.—E. C. FREMAUX, Rayne, La. The invention relates to that class of cabinets which are adapted to hold disk talking machine records. The primary object is to provide a simple and practical cabinet which

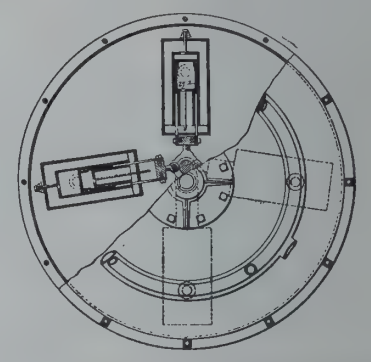
AN ELEVATION OF THE DEVICE

will insure the records being kept in their proper holders, each compartment having an individual locking device whereby the records may be selectively removed, and means for automatically and collectively locking the remainder of the compartments upon unlocking one of the compartments; when a record is removed it will be impossible to replace it in the wrong compartment.

FREE SOUNDING BOARD.—G. VIRZI, 341 E. 124th St., New York, N. Y. This invention may be applied to sounding boards of all kinds, especially all sorts of stringed instruments. The invention comprises the combination of a main sounding board, an auxiliary a character to prevent leakage between the two to hold the auxiliary board in definite spaced relation to the main sounding board, the securing means including a rib secured to one of said boards throughout its length, and having at least one integral extension to which the other sounding board is attached.

### Prime Movers and Their Accessories

INTERNAL COMBUSTION ENGINE.—A. P. HARDWICK, Box 231, Chowchilla. Cal. An object of this invention is to provide a double acting four-cycle internal combustion engine embodying as one of the principal features a reciprocating piston capable of compressing charges on both sides of the head and the



A SIDE ELEVATION OF THE CASING PARTS BEING BROKEN AWAY

cylinder heads between which the piston reciprocates. Another object is to provide a pivotal mounting for the relatively fixed cylinders, through the medium of which the cylinders may oscillate to accommodate the positions of the reciprocating piston without the use of a wrist pin.

ROTARY ENGINE.—C. MULINEX, Tolley, N. D. This invention is adapted for embodiment in either an engine or a pump and is adapted to employ any suitable motive fluid such as steam, air, or gas. The general object is to provide for the automatic sliding of the pistons to the power position and return without providing a side pressure thereon such as would cause binding of the pistons in the rotor, and to provide a construction of a character to prevent laekage between the rotor and starter.

ENGINE.—E. SARJENT, Kingfisher, Okla. The invention relates more particularly to a compound engine in which the otherwise waste gases are utilized to drive an expansion engine, which later may be utilized as a starting means for the internal combustion engine, a portion of the exploded gases from the internal combustion engine being stored in a receiver and supplied to the expansion engine as desired, the supply being under control.

VALVE EXTRACTOR.—E. T. LIESS, P. O. Box 512, Huntington, N. Y. The particular aim of this invention is to provide a device adapted for the extraction of valves from an internal combustion engine. A further object is to provide a device which can be made of any suitable material, preferably high grade steel, which may be made very light and strong, of cheap construction and easy to apply.

### Railways and Their Accessories

TRAIN COUPLING.—J. B. HOLLAND, 850 W. Fayette St., Baltimore, Md. An object of the invention is to provide a car coupling in which the brake and signal lines are operatively connected and combined in such a way that when two of the couplings are joined, as between two connected cars, a fluid tight connection will be established at once, such connection remaining firm regardless of the relative movement of the coupling members.

PULVERIZED FUEL BURNING DEVICE.—J. DICKSON, U. S. Natl. Bank Bldg., Vancouver, Wash. The invention relates more especially to devices for enabling locomotive engines to make use of pulverized fuel. An object is to provide a device by which pulverized fuel may be introduced into the combustion chamber of a locomotive by means of a stream of heated air so that the fuel is substantially consumed, leaving a relatively small amount of ash and giving a maximum quantity of heat.

## Making the Hetch-Hetchy Dam Itself

(*Continued from page 422*)

The tunnel level is really some distance from the very bottom, being at a depth of 575 feet. The excess depth of the shaft provides for a special pocket equipped to load skips by gravity and for a pumping sump. Another shaft providing for access to the tunnel is known as the Second Garrotte shaft. Its full depth is, or will be, about 820 feet, though the tunnel grade is only 756 feet below the surface.

In driving the headings, a round of 18 to 24 blasting holes is provided. When these are exploded, an advance of about 5 feet is made. The excavation is made in full section at single operations, so that no bench is left for later removal. The tunnel is ultimately to be lined with concrete. The minimum thickness of the lining is 6 inches. The cross-section is of horse-shoe shape, the toe of the shoe being naturally at the top.

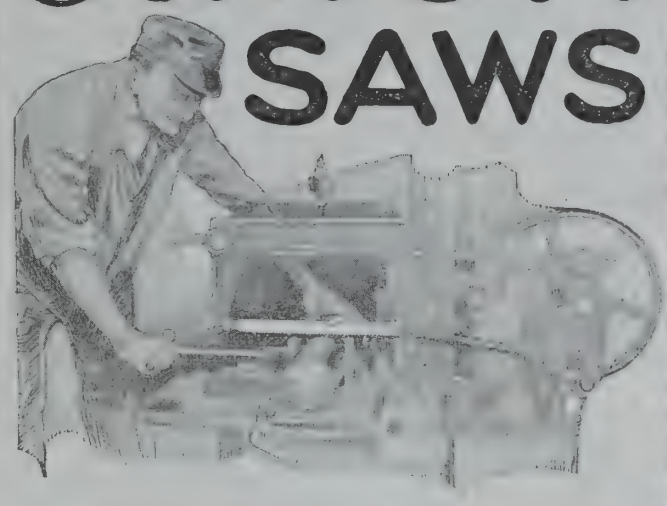
The power house which is located at Early Intake and whose pressure water comes from Lake Eleanor operates under a head of 346 feet and has a capacity of 4,000 hp. The use of timber flumes as part of the conduit which brings water from the diversion dam on Cherry River seems to have been dictated largely by the consideration that upon certain very precipitous mountain sides it would have been exceedingly expensive to excavate for a concrete canal. Later on, when conditions are more favorable, it is proposed to replace the flumes by tunnels, and to provide the necessary cross-cuts. The tunnel work may then be done without interruption to the operation of the plant. The manner of constructing the flumes on the steep mountain sides is of interest. A certain amount of excavation had to be done in order to provide for the support of the footings. This was carried to bed rock. The under part of the framing was put in place and the floor laid. A track was constructed of wooden rails and push cars loaded with lumber were shoved along on it. An immense amount of lumber was consumed—upward of 1,300,000 board-feet. The city cut this lumber at its own saw-mill, from which it went to the points of use.

The steel penstock is 42 inches in diameter. From the forebay down to the turbines which it serves, it is 530 feet long. The thickness of wall varies from 3/16 inch to twice as much. Naturally, the heavier wall is used in the lower sections, where the hydrostatic head runs up to a maximum pressure in the neighborhood of 150 pounds per square inch. The wheels are Pelton-Francis turbines operating in vertical planes. They are direct-connected to their respective generators. The current is developed at 2,300 volts, but is stepped up to 22,000 for transmission purposes. The lines are estimated to extend 19 miles on the west and 14 on the east. There are three units, although the plans called for the output of but two, the third being reserved for emergency use. The transmission line to the west lies in the same vertical plane with the tunnel underneath.

The Early Intake power house performed a certain amount of service during the fuel shortage of the Great War. It began operation as early as May, 1918, at a time when its full capacity was not required for aqueduct work. In September, the Power Administrator ordered that the transmission line be connected with that of the Sierra & San Francisco Power Company for the purpose of supplying surplus energy at points served by this commercial concern. In three days after the date of the formal order, the connection had been made and the delivery of surplus energy begun. In fact during the fiscal year 1918-1919, of the total output of 18,687,400 kw.-hrs., 13,505,621 kw.-hrs. were delivered for use other than that connected with the aqueduct.

The muck handling machine already referred to is a self-propelling apparatus.

SIMONDS
SAWS



Hack Saw Blades

Simonds-Made Hack Saw Blades are the most economical to use: they cut with less resistance, remove no more metal than necessary, and wear the longest.

This superior saw service is primarily due to the Simonds Steel that's put into these blades. It is a steel especially made and toughened for hard cutting service by an exclusively Simonds process developed in their own Crucible Steel Mill.

*There is a SIMONDS way to cut steel, wood, paper, ice, leather, cork, rags, etc.*

Write for Simonds booklet—"Methods of Cutting Metal."

## RECENTLY PATENTED INVENTIONS

(*Continued from page 436*)

CUT-OFF RELIEF VALVE FOR AIR BRAKES.—E. P. CLAUSS, 26 Maple St., Lyons, N. Y. This invention has for an object to provide a construction which will act as an angle cock substantially in the usual manner, but will act to bleed the system when turned off. Another object is to provide an angle cock which will bleed the system when turned off both in front and rear of the cock, and to be arranged so as to be unlappable.

RAIL.—N. I. WOOLSEY, 5474 Asbury Park Rd., Huguenot Park, S. I., N. Y. The invention relates to railroad and street car tracks; its object is to provide a rail arranged to permit of quickly replacing a worn out head by a new one without removal of the web and base from the track. Another object is to provide a protected passage for the electric conductor, and to prevent spreading of the rails.

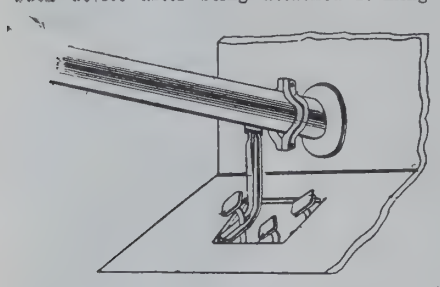
### Pertaining to Recreation

PUZZLE.—V. A. HLASKO, 36 Holland Park, London, England. The primary object of the invention is to provide a toy such as are commonly known as puzzles in which a plurality of element of different sizes are movable relatively to each other to position them according to their value, it being understood that each of the elements is given a different value.

### Pertaining to Vehicles

LOCKING DEVICE FOR AUTOMOBILES.—J. P. GERAGHTY, 493 Grove St., Jersey City, N. J. Means are provided within the hood enclosing the motor to prevent starting the motor and the hood is locked to prevent unauthorized persons from gaining access to said means. A plurality of devices are provided for rendering various parts of the motor inoperative so as to prevent even experts from stealing the car.

LOCK FOR AUTOMOBILES.—C. W. NIXON, 400 Bourbon St., New Orleans, La. The invention relates to locks for automobiles to prevent theft of the machine. An object is the provision of a locking device, which effectively locks a clutch pedal in neutral position, such device after being attached forming an



A FRAGMENTARY VIEW OF A FORD CAR WITH LOCKING DEVICE APPLIED

integral part of the machine, and constructed to prevent the prying or bending apart of any part of the device, in an attempt to remove the same from the pedal.

AUDIBLE ALARM FOR VEHICLES.—L. H. MORGAN, c/o The Ellengton Apln., Cleveland, Ohio. Among the objects of the invention is to provide means whereby when a vehicle is left standing unguarded it may be so adjusted that it cannot be moved without authority without the sounding of a loud alarm. The object is to provide an alarm device which may be easily applied to any standard vehicle in which there is a rotary shaft.

WIRE WHEEL.—T. A. BOWERS, 64 Sudbury St., Boston, Mass. An object of this invention is to so temper and crimp the spokes as to materially increase the strength of the wheel by taking up all internal stresses set up in the spokes under service conditions, the purpose being to make the wheel resilient and to increase its ability to withstand shocks and strains.

VEHICLE ROUTE INDICATOR DEVICE.—E. SIEGEL, c/o Siegel Bros., 154 Nassau St., New York, N. Y. Among the objects of the invention is to provide a road indicator by means of which road directions and land marks over a relatively great distance may be provided in a compact space, the mechanism being so arranged that the road characteristics or land marks may be shown upon a relatively large scale, and before the said marks are actually reached whereby the driver will have ample warning of same.

STAND.—E. H. KELLEY and G. A. STEWART, JR., South Brownsville, Pa. This invention has for its object to provide a stand especially adapted for use in repairing and testing engine cylinder blocks, particularly of the Ford type. The invention comprises a base, having at one side legs, and at the other side wheels for supporting the base, the base and legs being of angle material.

SIGNAL FOR MOTOR VEHICLES.—E. P. GOODCHILD, 2116 Monroe St., Spokane, Wash. Among the objects of the invention is to provide a signal which will indicate to following vehicles, and to those in front, the intention of the driver in regard to turning or stopping. The signal is in the form of an outstretched hand, adapted to be normally held in a casing, but extended and withdrawn at will by the driver.

TANK LOCK.—F. H. RUNDALL, 343 Peary St., Fall River, Mass. The invention relates more particularly to means for locking the caps or plugs of gasoline tanks on automobiles, an object being to provide a device which will prevent the theft of gasoline while tre car is standing in garages or elsewhere, as the cap can be removed only by an authorized person with the proper key.

TEMPERATURE INDICATOR FOR ENGINE WATER CIRCULATION.—G. P. PITKIN, Bergenfield, N. J. The invention provides improved means for supporting a thermometer on the dashboard of an automobile, airplane or other similar device. The thermometer is in direct communication with the water circulating through the cooling system so that the operator can see at all times the temperature of such water.

DIFFERENTIAL.—G. W. WILKIN, Box 962, Grangeville, Idaho. The primary object of the present invention is to provide a very simple differential gearing which will transmit power to all four wheels of a vehicle and which will permit of the turning or rotation of all four wheels independently of each other. Under normal conditions it will transmit a maximum of driving power to each wheel.

PNEUMATIC WHEEL.—E. B. HUDSON, 519 Crawford St., Middletown, Ohio. This wheel is so constructed as to eliminate punctures, blow-outs, and rim cuts. The pneumatic element is not placed at the periphery of the wheel but is introduced between the wheel and the hub while a solid rubber tire is mounted on the rim of the wheel.

SPRING WHEEL.—W. A. BURGER and W. GROSS, San Francisco, Cal. An all metal spring wheel is provided by this invention which is designed to take the place of a pneumatic tired wheel. The rim is composed of a series of movable sections which are cushioned by radially extending springs. The tension of these springs may be varied at will.

CONVERTIBLE AUTOMOBILE BODY.—J. J. MCGUIRE, 21 Sherman Ave., Yonkers, N. Y. The object of this invention is to provide a new and improved convertible automobile body arranged to permit of its being converted into a limousine, runabout, open car body or partly open car body. Another object is to provide sleeping accommodations in the limousine body.

OIL CUP—L. H. WILLIAMS, c/o R. L. McDonald Mfg. Co., Box 1177, St. Joseph, Mo. The invention relates to a form of oil cup that is adapted to be attached directly to a leaf-spring of an automobile whereby a lubricating oil is fed as needed between the leaves composing the spring. A further object is to provide a device that can be quickly attached or detached without the necessity of using any tools.

AUTOMOBILE COWL ATTACHMENT.—J. H. COFFMAN, 201 Waverly Way, Atlanta, Ga. This invention has for its object the provision of a cowl construction whereby to provide a gutter located beneath the juncture of the hood with the cowl whereby to prevent water from dropping down onto the coil box terminals and ignition wires connected therewith.

### Designs

DESIGN FOR A STAND.—W. F. FAAS, Cleveland, Ohio.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

Hobart Building, SAN FRANCISCO, CAL.

One of the sizes has a weight of 18,500 pounds and a length of 22 to 26 feet. It may be driven by a 20-hp. motor or by compressed air. This machine is said to have a capacity in loose material equal to the loading of 200 to 300 tons per day of 8 hours. Naturally, in rock and in the confined space of a narrow tunnel, the capacity would be much less. The crew consists of three men—one to operate the handling feature, one to shift the cars, and one to couple up cars. This apparatus may be mounted on a track or it may be equipped with traction "wheels." It delivers to cars immediately to the rear or to cars alongside. The shovel which recovers the spoil and loads it on to a short conveyor is a curious device. It is driven by a crank which rotates continuously in a single direction and which is carried on a curved track. It may move downward, upward or forward, and may be turned to discharge its contents on to the aforesaid conveyor. In the big machines the shovel goes through its cycle 13 times per minute. With machines of this and similar types the question of successful performance of the duties required is only one part of the problem. It is highly important that the design be sufficiently simple and the construction sufficiently rugged to avoid frequent shut-downs and expensive repairs. In the past there has apparently been a good deal of difficulty in designing and building machines for cutting and mucking in tunnel headings that fulfil all the requirements.

## A Magnetic-Proof House for the Workers

(*Continued from page 423*)

instruments and appliances for the investigational work is entirely non-magnetic in character. The heating is provided by a central steam-heating plant in the main laboratory about 250 feet distant. The radiators are of copper tubing. The steam, return, gas, hot and cold water, drain and air pipe lines and lead-encased electric cables are hung in a concrete tunnel sufficiently large to allow alterations and additions. All of these lines and their mountings are non-magnetic in character within the building and for a distance of forty feet outside. The laboratory tables and galvanometer mountings are of carefully selected soapstone free from magnetic impurities. Provision is made for three alternating current circuits and fourteen direct current circuits between the laboratory and the main building.

The plans, design and details of the Experiment Building were prepared by J. A. Fleming of the Department Staff and the work carried out under his direction.

## The Romance of Invention—XVIII

(*Continued from page 424*)

met calculates that the saving amounts to three per cent of the total capacity of the ship, which saving is accompanied by the further advantages of saving in weight; for electric drive units weigh less than any other type of drive, without consideration of the fifty or sixty tons of weight saved in the elimination of the usual propeller shaft, bearings and gear.

Personally, Mr. Emmet is a fluent talker upon subjects which interest him, possessed of a viewpoint almost wholly scientific, and with a modesty of thought about his work which is very pleasing. From childhood he had a love for mechanical things and as a boy did much carpentering and other mechanical work. He states that he had "no remarkable skill or facility, but the enterprise to begin difficult jobs and the persistence to carry them through."

Much of the faith and initiative necessary to start and carry through important new work has been his, in addition to a large amount of invention and much thought and experimentation both as to proportion and general economic characteristics and as to details of construction. Of his work with the General Electric Co. he says: "In all my work at Schenectady I have held to engineering and avoided as much as possible executive activities, but have had to do much in organization and direction of new undertakings and also in selling new things—which can generally be accomplished by those who have complete faith based upon positive knowledge. I have always realized that there was a great number of possible undertakings in which the energies of a good engineer would bear good fruit, and I have generally had many such in view; but I have confined my best efforts to a few important campaigns which in my opinion conduced to large developments of the electric art.

"Since I have been in the manufacturing end of the electric industry, I have mainly devoted my energies to four large undertakings. The first of these was the development and promotion of electric distribution by alternating currents, a movement in which many were engaged but in which I planned, and to a large extent executed, some of the most important initial steps. This activity lasted from 1894 to 1905.

"My next important undertaking was the Curtiss turbine development, which extended from 1900 to about 1912, when I began to leave its principal direction to others.

"My third important activity was the electric propulsion of ships. This, as applied to warships, extended from 1909 to 1919 and the campaign is at present being extended to merchant ships.

"My fourth important activity has been my mercury-vapor process, which has been worked upon since 1913 and has not yet reached a state of commercial development. This process is entirely my own work, every detail of conception, experimentation and actual design has been worked out by me, with practically no help but that of my personal assistants and draughtsmen working in my office. Very important demonstrations have been made, a large commercial application is now being begun, and I believe that the process will develop very great importance."

Mr. Emmet has more than a hundred patents to his credit, ranging over the whole field of electrical and steam engineering. He has just received the Edison medal, a distinguished honor which his conferes in electrical and steam engineering circles say has been well and honestly earned.

## A Mechanical Age for the Farm

(*Continued from page 426*)

oratory, farm lighting laboratory, farm hydraulics laboratory, and lecture room. There is a special building at the rear of the main building for the tractor testing work.

A great number of the students who take these courses go back to the home farm, but those who aspire to the most advanced work often plan on entering the agricultural engineering field as professional men. There has been a shortage of men who are professionally trained in these lines and the large implement and tractor companies are on the alert for the best talent. It was only a comparatively few years ago when 100 students taking work in agricultural engineering was almost an epoch-making event but there are now over a thousand a year taking such work at the University of Nebraska. Needless to say, not all of the students take all of the courses but agricultural engineering has come to be recognized as one of the branches to be learned by the scientific farmer. No better illustration of the great demand for mechanical information on the farm can be gained than the fact that the two or three letters of inquiry a week have now often passed the 500 mark.

But the tractor testing probably represents the most important piece of work attempted. The tractor purchaser is not

## LEGAL NOTICES

# PATENTS

IF YOU HAVE AN INVENTION which you wish to patent you can write fully and freely to Munn & Co. for advice in regard to the best way of obtaining protection. Please send sketches or a model of your invention and a description of the device, explaining its operation.

All communications are strictly confidential. Our vast practice, extending over a period of seventy years, enables us in many cases to advise in regard to patentability without any expense to the client. Our Hand-Book on Patents is sent free on request. This explains our methods, terms, etc., in regard to **Patents, Trade Marks, Foreign Patents, etc.**

in a position individually to make tests to show whether or not a tractor comes up to the claims made for it. One of the difficulties in purchasing a tractor has been the fact that horse-power ratings have not always been true indications of tractor capacity. Some manufacturers have overrated their tractors, others have underrated. The result has been that farmers have sometimes secured tractors too large or too small for the work to be done, and have also secured machinery too large or too small for the tractor. The results of tractor tests under the new tractor law will give tractor purchasers the information they need regarding horse-power capacity of tractors.

Under the law each tractor manufacturer must deliver his tractor to the university and a temporary permit is issued until the test is completed. One provision of the law is that the manufacturers cannot use the results of the tests for advertising purposes unless the complete results are also published, thereby preventing them from telling only the good points of their tractor in the test. The following is a complete list of the tests that the tractors are obliged to pass:

1. Drawbar work at one-third load to full load for 12 hours. This test gives opportunity for the tractor to limber up.

2. Brake horse-power test at rated load and rated speed for two hours. This test will show whether or not the tractor will carry its rated load on the belt; also show fuel consumption at rated load.

3. Brake horse-power test at load varying from maximum to no load with all engine adjustments as in test (2) for one hour. This will show fuel consumption and speed-control on varying load.

4. Brake horse-power test at maximum load for one hour with governor set as in test (2) and carburetor adjusted for most economical operation at one-half load. This test will show fuel consumption at one-half load.

6. Drawbar horse-power test at rated load for ten hours. This test will be made on a half-mile cinder track and will show whether or not the tractor will carry its rated drawbar load continuously; also shows fuel consumption on drawbar work.

7. Maximum drawbar horse-power test. This test will be a series of short runs with an increase of load for each run until the engine is overloaded or the drive wheels slip excessively.

8. Miscellaneous. This may include investigation of work on inclines, turning radius, effectiveness of brakes, or any feature of the tractor which may seem to require special observation.

9. Tractors will be under observation for endurance throughout the complete test as outlined above.

A half-mile cinder track has been constructed for the tractor drawbar tests. A special dynamometer car ras been built on a tractor chassis, with an electric generator in place of the engine. A tractor dynamometer gives the record of the drawbar pull, distance traveled and time.

To make the tests of the tractor work on the belt an electric dynamometer has been installed in a building erected for that purpose. Fuel consumption is recorded by drawing the fuel from a tank mounted on a scale. The entire tests are passed on by a board of three engineers. Needless to say, all the operating of the tractors is done by the university, although the company may have a man present.

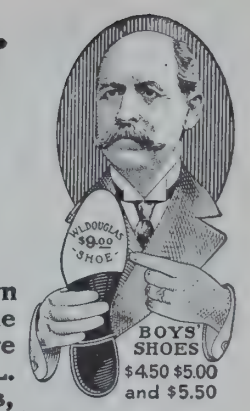
It was a noteworthy fact at the dedication of the new building that several of the speakers called attention to the somewhat primitive agricultural implements that they were compelled to use as boys on the farm. The last thirty years have seen marvelous strides in the development of factories, and the next thirty years will see the development of some wonderfully efficient farms. In truth, the farm is a factory and the farmer is still entitled to all the labor-saving devices that can be mobilized for his aid.

# W. L. Douglas

THE SHOE THAT HOLDS ITS SHAPE

**$7.00 $8.00 $9.00 & $10.00 SHOES**
**FOR MEN AND WOMEN**

***YOU CAN SAVE MONEY BY WEARING W. L. DOUGLAS SHOES***



BOYS' SHOES $4.50 $5.00 and $5.50

The best known shoes in the world. They are sold in 107 W. L. Douglas stores, direct from the factory to you at only one profit, which guarantees to you the best shoes that can be produced, at the lowest possible cost. W. L. Douglas name and the retail price are stamped on the bottom of all shoes before they leave the factory, which is your protection against unreasonable profits.

W. L. Douglas $9.00 and $10.00 shoes are absolutely the best shoe values for the money in this country. They are made of the best and finest leathers that money can buy. They combine quality, style, workmanship and wearing qualities equal to other makes selling at higher prices. They are the leaders in the fashion centers of America. The stamped price is W. L. Douglas personal guarantee that the shoes are always worth the price paid for them. The prices are the same everywhere; they cost no more in San Francisco than they do in New York.

W. L. Douglas shoes are made by the highest paid, skilled shoemakers, under the direction and supervision of experienced men, all working with an honest determination to make the best shoes for the price that money can buy.

W. L. Douglas shoes are for sale by over 9000 shoe dealers besides our own stores. If your local dealer cannot supply you, take no other make. Order direct from factory. Send for booklet telling how to order shoes by mail, postage free.

CAUTION.—Insist upon having W.L.Douglas shoes. The name and price is plainly stamped on the sole. Be careful to see that it has not been changed or mutilated.

## CONDITIONS FOR THE $5,000 PRIZE EINSTEIN ESSAY CONTEST

1. No essay shall be longer than 3,000 words.

2. All essays must be in English, and written as simply, lucidly and non-technically as possible.

3. Each essay must be typewritten, and identified with a pseudonym. The essay shall bear a title and the author's pseudonym *only*, and must be enclosed in a plain sealed envelope likewise bearing this pseudonym. In the same package with the essay must be sent a second plain sealed envelope, also labelled with the pseudonym, and containing a statement of the name and address of the contestant, the pseudonym used, and the title of the essay. It is necessary to follow these instructions implicitly, in order to guard against confusion in opening the envelopes and assigning the pseudonyms to their proprietors, especially in view of the possibility that two of the contestants may employ the same pseudonym. The envelopes should be sent in a single package to the Einstein Prize Essay Editor, SCIENTIFIC AMERICAN, 233 Broadway, New York.

4. All essays must be in the office of the SCIENTIFIC AMERICAN by November 1st, 1920.

5. The Editor of the SCIENTIFIC AMERICAN will retain the small sealed envelopes containing the competitors' names and addresses, which will not be opened until the competitive essays have been passed upon and the winning essay selected.

6. As soon as the judges have selected the winning essay, they will notify the Editor, who will open the envelope bearing the proper pseudonym and revealing the competitor's true name. The competitor will at once be notified that he has won, and his essay will be published in an early issue of the SCIENTIFIC AMERICAN.

7. There shall be but one prize, of FIVE THOUSAND DOLLARS, to go to the author of the best essay submitted.

8. The SCIENTIFIC AMERICAN reserves the right to publish in its columns, or in those of the SCIENTIFIC AMERICAN MONTHLY, or in book form, any of the essays which may be deemed worthy of this. Aside from such rights, the essays shall remain the properties of their authors; but no manuscripts can be returned.

9. The Committee of Judges will consist of Professors Leigh Page of Yale and E. P. Adams of Princeton. In the event that they are unable to agree on the best essay, the Einstein Prize Essay Editor will cast the deciding vote.

# DURAND STEEL RACKS

DURAND Steel Racks are the product of engineering forethought and skill.

The skill has gone into the strength and rigidity of their construction, and the accurate fitting of every part.

The forethought has gone into their design — their adaptability to every storage purpose—and the careful selection of material.

## Extracting Oil by Electrolytic Action

(*Continued from page 428*)

rators. The solid matter, when pressed, dried and granulated, makes excellent feed for chickens and hogs, containing from 60 to 70 per cent protein, or it can be used as a fertilizer. The entire process is an odorless one, and only a very limited amount of labor is necessary to keep a plant in operation. The installation at Gloucester has 12 coils or cells in the electroytic unit, but even so the equipment is capable of turning out 50 barrels of cod liver oil in eight hours, each barrel holding 400 pounds.

Excellent results have been realized in handling entire fish when suitably cut up or ground to make it possible, after admixture with the saline electrolyte, to pump the stuff through the extracting unit. No matter whether the flesh of shark, menhaden, herring, etc., be used, the quality of the oil and the quantity are both much superior to the yields secured by other means. As might be expected, the Roger's-Bennett system is showing its flexibility in dealing with butcher's trimmings and the better grades of fat. By the best practice in vogue the tallow yield does not exceed 45 per cent, while the electrolytic unit gives 60 per cent and the oleo recovery reaches 90 per cent by the newest apparatus as against a maximum of 82 per cent by up-to-date commercial equipment.

These gains in output are likely to pay handsomely. Just how much so can be grasped from a report issued by the Bureau of the Census covering the three-month period ending June 30 of the current year. The factory production of fats and oils was as follows: Fish oils, 19,737,357 pounds; animal fats, 436,674,135 pounds; grease, 100,799,825 pounds; and vegetable oils, 276,647,937 pounds. And this brings us to the adaptability of the electrical process to the extraction of oils from vegetable sources.

Up to the moment, the method has been applied only to copra, the well-known form of dried cocoanut from which we get a great deal of the basic material for nut butter and other edible commodities, not to mention oil for various purposes. Copra has a cellulose fiber which necessitates the grinding or thorough macerating of the cocoanut in order to stimulate the fullest electrolytic action. When this is done, the extraction of the oil is practically on a par with that effected when dealing with animal matter, and the product is of a high grade. There is every reason to believe that this novel system will prove a boon in the extraction of oil from linseed, soya beans, castor beans, cottonseed, peanuts, corn, and many other fatty or oil-bearing vegetables.

## San Francisco's Traffic Convention and Street Safety Show

By C. W. Geiger

(*Continued from page 431*)

word signs which govern traffic, just as the traffic officers do today. These signals may be manipulated locally or connected with a central timing device which operates for any desired length of time at any desired interval. This device was perfected by a Los Angeles inventor, and is now being installed at several street intersections in that city.

The semaphore is placed on an ornamental post at the property line of the intersection of streets, so as to be visible to all traffic. Four devices at each intersection, with the semaphore, a light and a bell giving three signals at the same time, permit traffic to proceed or stop. These signals are connected with a central timing device operated automatically for any length of time desired, so that an entire street may be thrown open for traffic north and south, and closed east and west. Then, on the other hand, all east and west streets may be thrown open for traffic and the others closed, or if it were desirable to open a street north and south at one intersection and close it at the next intersection sychronously, it may be done. There is in fact no movement of traffic which can be suggested that cannot be accomplished with this regulator. The signals are plainly visible and audible day or night, and always in operation. Traffic is always regularly moving, and for any time desired in any direction with absolute safety.

There is provided either central or local control at each intersection, at all times, so that an officer may instantly assume control, at any intersection, at will. It has been suggested that this device may prove practical to supplement the regulation at every congested intersection, with a traffic officer during certain hours; however, this is not necessary, as the device completely regulates the traffic. The traffic officer, however, will be used at intervals, as there will be infractions of the traffic regulations, and this device will aid the officer in enforcing regulation, as he will not be required to be stationary.

The regulator can be used by the fire department and the police department in many ways. In order to permit fire department equipment to pass, traffic on any or all streets can instantly be brought to a standstill, if desired. This is possible because the system is so arranged that all four arms bearing the word "stop" can be raised, and all four arms bearing the word "go" lowered, thus stopping traffic.

## Use of Pulverized Lignite for Fuel in Australia

A NEW Australian syndicate has been registered at Melbourne "to mine, process, and deliver to prospective customers throughout the Commonwealth" pulverized lignite, or brown coal, which, it is claimed, can be used for steam generation or metallurgical purposes with most satisfactory results. The syndicate controls various brown-coal deposits throughout the State of Victoria, said to contain over 250,000,000 tons, and mining operations are well under way.

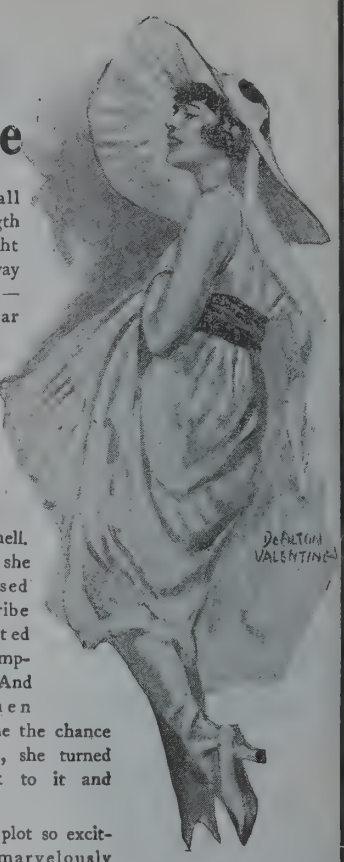
Many novel features have been introduced in mining and air-drying the lignite, as well as in the process of pulverizing and burning. The plans for the entire work were prepared by Roy N. Buell, of San Francisco, Cal., chief consulting engineer, and the plant which the company recently built at Abbotsford (a suburb of Melbourne) was erected under his personal supervision. His views on the subject of the treatment of brown coal in Australia are embodied in this report.

The most striking improvement in this new method of treating lignite, which is known as the "Buell system," is the means of air-drying at the mines, whereby the moisture content is reduced from 50 to 25 per cent in seven days. Briefly described, the process is as follows:

The lignite is mined in either shafts or open cuts, the coal crushed on the spot to egg size, then hoisted to the air-drying tipples at the surface by bucket conveyors. After drying about seven days, the coal is relieved of practically half of its moisture content and is ready for final treatment. This final process, which should be undertaken near the place where the fuel is to be used, consists of again crushing the coal—to about ½-inch mesh—after which it is passed through a rotary drier, where the moisture content is reduced to about 10 per cent. The fuel is then pulverized, separated by air, and stored in bunkers.

To use it is blown through pipes, where it is mixed with air in quantity 10 per cent in excess of requirements and ignited at the tip of an adjustable burner, which enables the length and width of the flame zone to be most accurately gaged. Boiler tubes and baffles are kept clear of ash by soot blowers and suction conveyors carry off the ash to any desired place of disposal. Three per cent of the power generated is required to operate the plant, and one experienced man can fire a whole battery of boilers or kilns.

**The Slave**



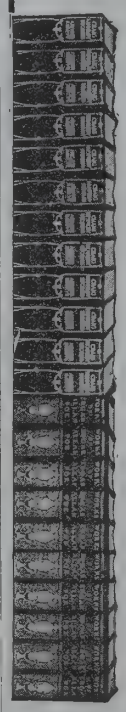
With all her strength she fought to get away from it all—the vulgar cabaret—the mysterious beauty parlor—the underground drinking-hell. Fiercely she had refused every bribe—resisted every temptation. And yet, when there came the chance to escape, she turned her back to it and stayed.

It is a plot so exciting—so marvelously planned—so brilliantly solved—that it could have been written only by the master detective

**CRAIG KENNEDY**
*The American Sherlock Holmes*
**ARTHUR B. REEVE**
*The American Conan Doyle*

He is the detective genius of our age. He has taken science—science that stands for this age—and allied it to the mystery and romance of detective fiction. Even to the smallest detail, every bit of the plot is worked out scientifically. For nearly ten years America has been watching this Craig Kennedy—marvelling at the strange new startling things that detective-hero would unfold.

Such plots—such suspense—with real, vivid people moving through the maelstrom of life!



# FREE—POE

**10 Volumes**

To those who send the coupon promptly, we will give FREE a set of Edgar Allan Poe's masterpieces in 10 volumes. When the police of New York failed to solve one of the most fearful murder mysteries of the time, Edgar Allan Poe—far off in Paris—found the solution—the story is in one of these volumes.

This is a wonderful combination. Here are two of the greatest writers of mystery and scientific detective stories. You can get the Reeve at a remarkably low price and the Poe Free.

Cut out this coupon and mail it today

HARPER & BROTHERS, 21 Franklin Square, New York Sc. Amer. 10-23-20

Send me, all charges prepaid, set of Arthur B. Reeve—in 12 volumes. Also send me, absolutely free, the set of Edgar Allan Poe—in 10 volumes. If the books are not satisfactory, I will return both sets within 10 days at your expense. Otherwise I will send you $3.50 within 5 days and $3.00 a month for 12 months.

## Tiny G-E Motors Are No Exception

THE mention of a trolley car, hydro-electric plant, or any other prominent use of electricity, invariably brings the G-E trademark to mind.

But every day this same company is producing thousands of tiny motors as well. The knowledge and research required to build one-twentieth horsepower motors for hand drills or jewelers' lathes may be just as great as that required for a huge boring mill motor or a unit to propel a battleship. The skill and care in manufacture is even more exacting, because of the miniature dimensions and the quantities produced.

Manufacturers of small motor driven devices of the highest grade recognize these facts, and secure the advantages of long time motor service by building G-E motors into their machines.

Inherent quality may not be evident to the casual observer; in fact, the motor itself is often concealed; but the man who investigates, recognizes the value of a quarter of a century's successful production and application of G-E motors to all types of electrically operated machines.

## The True Role of Water Power

By C. D. Wagoner

AFTER 10 years of contention and a serious drain on the coal and oil fields throughout the country, the door has been thrown open for "white coal" to serve industry and the home by the signing of the water power development bill. The vast water powers of the country may now be utilized.

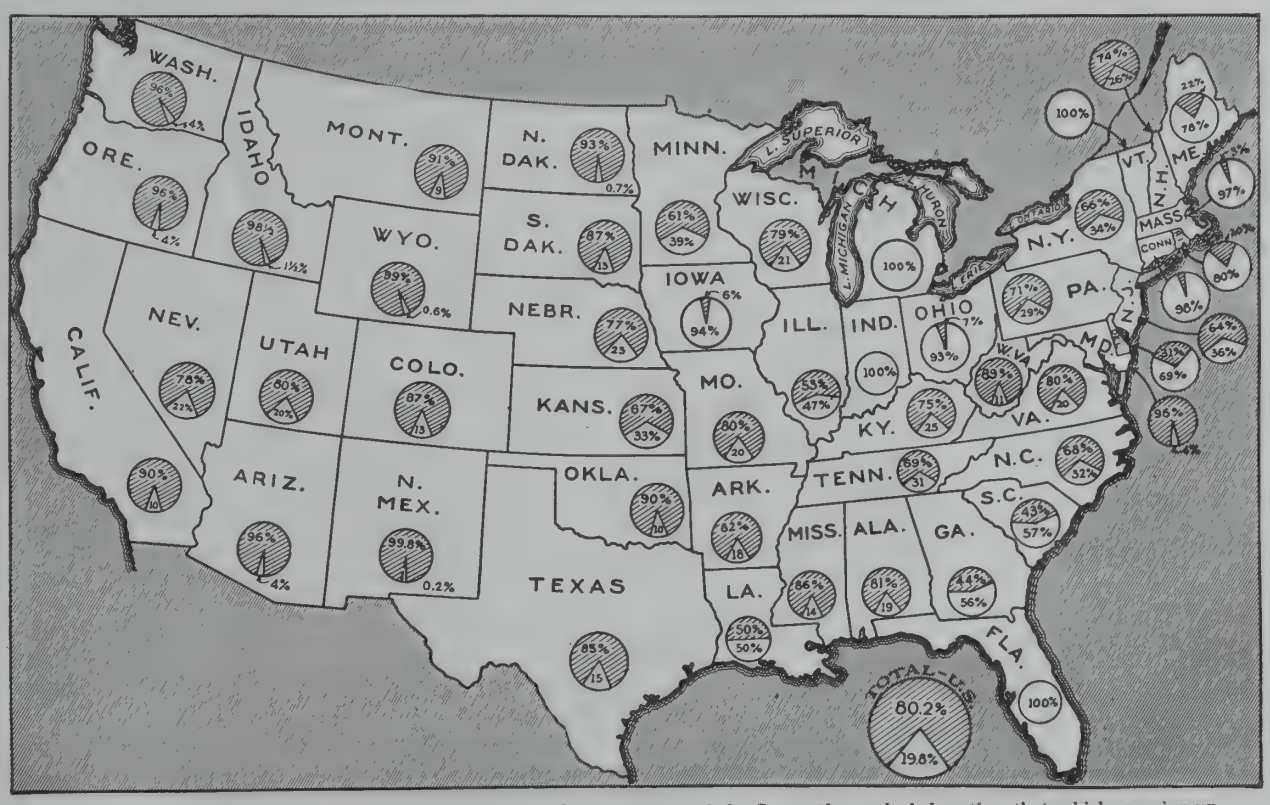
Fifty million horse-power comprises the total, both steam- and water-generated, now in use in the United States. It is conservatively estimated that as much more can be developed by utilization of the water power resources. The Department of the Interior has placed the potential water power at 60,000,000 horse-power of which but 10,000,000 is now developed. This saves the country upward of 33,000,000 tons of coal annually.

Assuming that a steam-produced horse-power generated daily for 12 hours throughout a period of twelve months requires the consumption of five and one-half tons of coal, the substitution of 50,000,000 horse-power from water should make an annual saving of 275,000,000 tons of fuel and avoid the movement of 7,000,000 freight cars. The economic gains, if we made use of our falling waters, would be tremendous, yet there is in service today but 10,000,000 horse-power developed by hydro-electric plants.

It is not contended that water power can entirely take the place of coal. In some instances a substitution for "black coal" cannot be made, but as a supplement it will add greatly to the total, pull down the average cost per unit, set electricity to work in the home far more extensively than at present and bring about such public comforts as the substitution of electricity for coal has done on some of the larger railroads.

But the power of our water can never completely replace the use of coal and oil for power purposes. While the new Federal legislation is a big forward step in fuel conservation, the maximum possible hydraulic energy of the nation is little more than the total energy which we now produce from coal and is about equal to the present total energy consumption of the country including all forms of energy. This means that the idea that when coal once begins to fail we may use the water power of the country as the source of energy, is, and must remain a dream. If all our potential water powers were developed and every rain drop used, it would not supply our present energy demand. Thus hydraulic energy may and should supplement that of coal, but can never entirely replace it as a source of energy. This probably is the strongest argument for efforts to increase the efficiency of our methods of burning coal, and to place at the disposal of the internal combustion engineer both new sources of petroleum fuels and new fuels of non-petroleum nature.

In this country the production of oil has already passed its peak, and in the world as a whole it will in a comparatively few years become of diminishing importance as a power producer, according to experts. There are still large reserves of coal in this country, though the greater ones are in the distant West, and the coal-producing countries are still far from exhaustion, but with the double price of coal, due in part at least to the increased cost of getting it out of the ground, coal-made power will be on the steady rise, it is predicted. In the creation of power, coal and oil are consumed and cannot be replaced. Therefore, it is asserted, the country which in future competition depends wholly or in great part on coal and oil power will be in a position of increasing disadvantage. On all these grounds the full development of our water power is something to which we must give attention.



The shaded section in each circle indicates the developed water-power of the State; the unshaded section that which remains undeveloped. No attempt is made to compare or even to state total developed or potential horse-power for the several States as against each other, but merely to show how far each State has gone in the utilization of such resources as it has.

**The extent to which the States of the Union have harnessed the power of their white coal**

## Repairing the Propeller of a Destroyer

THE *Panama Canal Record* describes an interesting repair made on the starboard propeller of the destroyer "Thornton," in the 1,000-foot dry dock at Balboa in May. The propeller had been damaged by touching one of the banks while in transit through the Canal. The ends of the blades had been turned back through half of a circle. The blades were straightened and brought back to their original surface. Cracks were welded, the broken tips of two blades were repaired by burning (casting new metal into a mold at the end of the tips so that it fused with the old metal), and the propeller was balanced and replaced.

Inasmuch as this is a high-speed turbine propeller, transmitting heavy horse-power and attached to a light hull, lack of balance or truth of surface in the repaired propeller would have set up a serious vibration. After the destroyer had gone to sea the commander telegraphed that the propeller was performing very satisfactorily, and congratulated the Panama Canal on "a difficult repair well carried out."

## The Rate of Speed at Which Bacteria Travel

WHEN one observes by means of the ultra-microscope the germs moving in a suspended drop of liquid one is frequently struck not merely by the fact that the form of the trajectory differs according to the species, but also by the difference in the rapidity of travel, which is often very considerable. Some of them move almost indolently, while some travel with great agility in one direction or another, and still others cross the field of observation at such a rate of speed that they give the impression of the flight of an arrow.

The average speed of each species of bacteria can be approximately calculated if one takes care to follow the course, in a suspended drop containing only a few germs, of the individuals which cross the field as nearly as possible along the line of the diameter, from one point to the opposite point on the circumference.

Mr. G. Sanarelli, the Director of the Institute of Hygiene of the University of Rome, continuing the researches previously made by Gabritschewsky, Stigell and Lehmann, and Fried, has determined the speed at which the cholera vibrion travels when the surrounding temperature is 25 degrees Centigrade, with cultures of various stocks 24 hours old developed upon agar-agar and afterwards painstakingly diluted in the serum of the guinea pig.

He found that the apparent average speed of motion is 10 centimeters per second; the actual speed corresponding to this is 0.125 millimeters per second, *i. e.* 7.5 millimeters per minute or 45 centimeters per hour. However, these figures are incapable of giving an idea of the dizzying rapidity of the vibrion as seen in the microscope. This is because the impression of speed obtained does not depend upon the *effective* speed but upon the *angular* speed. Regarded from this point of view the motion of the cholera germ give the same impression as a train passing in front of an observer at a distance of 40 meters at the rate of 16 meters per second or 57.6 kilometers per hour. The cholera germ travels at a much faster rate than any other microbe examined by Mr. Sanarelli, moving three times as fast as the *B. prodigious* and the *B. pyocyanus*, five times as fast as the *B. typhus*, ten times as fast as the coli bacillus and the *Proteus vulgaris*, and twelve times as fast as the *B. megatherium*.

Since all of these bacteria are provided with a number of cilia, while the cholera vibrion has as a rule only a single one, the rapidity at which microbes move appears to bear no connection with the number of their organs of locomotion.

## New York and the Proposed St. Lawrence Waterway

WE have already gone on record as being opposed, so far as New York State and City are concerned, to any diversion of effort from the recently completed barge canal to the proposed waterway through the St. Lawrence River. This does not mean that we are opposed to the St. Lawrence project as such. On the contrary, we believe that as an engineering project it is feasible and that commercially it will ultimately prove to be of great benefit not only to the Western States but to the State of New York and to the industrial centers which lie between the Erie Canal and the Canadian border.

The Erie Canal is an accomplished fact. Excellently built and showing everywhere today its full depth of twelve feet of water, it remains now to furnish the canal with two essentials to its success: first, adequate and thoroughly up-to-date terminals with public grain elevators at Buffalo and New York; and secondly, the removal of Federal operation, limited though it is, and the sale of the present Federal-owned barges to private operators—this last a movement which would encourage private capital to construct a fleet of barges adequate to handle the growing traffic of the canal. We are among those who believe that if these things be done, the new waterway between the Great Lakes and New York Harbor will fulfil all the promises upon which the State was led to commit itself to the labor and cost of construction.

The St. Lawrence project is of a totally different character from that of the State Barge Canal. An International Joint Commission is conducting a series of hearings, both in Canada and the United States, designed to gain information and gage public sentiment upon a scheme for deepening the St. Lawrence River so that it can be used by vessels drawing at least 25 feet of water. The work would be done jointly by the United States and Canadian Governments. The latter has already spent much money upon the St. Lawrence route and is committed to further expenditures. At present it is reconstructing the Welland Canal, which is to have a depth of 25 feet, the total cost of this work being about one hundred million dollars. The work is about one-third completed; but it is realized that the full benefit of this outlay cannot be secured unless the St. Lawrence is rendered navigable to a similar depth. The distance from Lake Ontario to tidewater at Montreal is 181 miles, and the work to be done in deepening the river will be confined to 46 miles of this distance.

The great delay in moving last year's crops, which was due to the congested state of the railroads, has naturally stimulated interest in the proposed St. Lawrence waterway; and it is believed that if deep-sea ships of from 5,000 to 9,000 tons could pass freely between the shipping ports of the Great Lakes and the various ports of the world, not only would the wheat-growing interests of our Western States be benefited, but there would be a very considerable development of other traffic.

On the other hand, it must not be forgotten that the St. Lawrence route will always labor under certain serious disadvantages which can never be removed. For several months of the year the river is closed by ice; and furthermore, even when the river is clear, it is subject to fogs which, as many disasters have shown, render navigation hazardous and naturally tend to increase insurance charges.

To many of us the incidental advantages of opening this waterway seem to be of even greater promise than its direct advantages as a deep-sea route from the Lakes to the Atlantic. The incidental advantages are that the fall of the river and its great volume open up large possibilities of hydraulic-electric development. Thus, in the so-called international section, the river falls 91 feet in 68 miles, and in the Canadian section it falls 130 feet in 70 miles. Preliminary study of the question would indicate that in view of the uniform and heavy flow of water throughout the year, the improvements of the river for navigation will make available a sufficient volume and head of water to produce approximately four million horse-power in the stretch between Lake Ontario and Montreal. The estimated cost of the necessary improvements runs up to three hundred million dollars; but it is believed that the full development of the hydraulic energy would provide sufficient income to pay interest upon the whole cost of the work. So rapid has been the improvement of long-distance transmission that the power thus developed could be made to serve the upper half of New York State, including the cities that border upon the Erie Canal, and it would also be available in New York City and throughout the greater part of New England.

The resulting reduction in coal consumption and the lower cost of power to the industries should appeal strongly to such a manufacturing center as New York State. The Western States naturally are more interested in the improved navigation. In any case, this project is too large and contains too much promise for the future to be ignored or actively combatted by the people of this State. When the Government engineers shall have finished their surveys and a detailed and reliable report on this great project has been presented and passed upon by the International Joint Commission, the city and State of New York will be in a position to judge dispassionately of the merits of the problem. Meanwhile, it will be a good business policy to bend every effort to the development of our own recently completed waterway.

## Admiral Benson on Our Merchant Marine

AS a declaration of the aims and policy of our Shipping Board and a statement of the scope of its operations, the recent address of its chairman, Admiral Benson, will be welcomed by those who are following with close attention the operations of that great governmental institution. It is to be regretted that public interest in this matter is not more widely spread. For not alone are the maritime States and, more particularly, the leading ports of this country concerned in our merchant marine, but the great interior States, if they could only be brought to realize it, have an interest that is equally vital.

We are glad to note that Admiral Benson at the outset deprecates the notion that our great shipbuilding effort is promoted merely by a spirit of rivalry. He points out that the operations of the Shipping Board have grown to their present magnitude as the result of war conditions. Previous to the war we were content to see our commerce carried in the bottoms of other nations, and it was not until we were urged by our allies to engage in shipbuilding on a stupendous scale that we attempted to rehabilitate our fast diminishing fleet. At a time when the civilization of the world was at stake we were told that the crying need was for ships and yet more ships. How promptly we responded is a matter of record, and the coming of the armistice found us at the high peak of our effort.

The Shipping Board came into existence several months before we entered the war, and its real purpose was to serve as a regulatory body of shipping, with vast powers that could be utilized to build up our merchant fleet. The magnitude of our accomplishment is seen in the fact that between the declaration of war and the time when our men were ready for hostilities, 95 per cent of their supplies and about 45 per cent of the men themselves were carried over in American bottoms.

We have a total deep sea fleet of over ten million tons; more than half of this is represented by the Shipping Board fleet; and naturally the latter includes the newest and most efficient of our vessels. Having this fleet, and our production of merchantable goods, raw and finished, being greater than ever before in our history, it is the purpose of the Shipping Board to bend every energy to the carrying of these supplies, or at least of the greater part of them, in American bottoms. Admiral Benson states that it is essential that the world should understand that while we fully appreciate the service hitherto rendered by other nations, we are now ship-independent in the development of our ocean-carrying trade.

We are glad to note that the chairman goes on record once more as being thoroughly in favor of private ownership. He tells us that he would use his influence to bring it about "that not only my own but other governments be brought to a point where they fully agree to retire absolutely from ocean carriage," since this would mean only uneven competition with the private owner. "We are endeavoring to do this," says the chairman, "as quickly as possible—and the law demands it."

## Radio Control of Naval Units

DOWN through the long history of naval warfare and particularly during the last fifty years of it, successive inventions have been hailed upon their appearance as being "revolutionary." Armor plate, the rapid-firing rifled gun, the torpedo, the torpedo boat, the submarine and now the airplane, have been quoted as destined to turn everything naval upside-down, and lead overnight to the scrapping of the existing instruments of battle and the substitution in their place of the new wonder. In varying degrees, but in infinitely less measure than was predicted, the successive inventions have modified the art, or rather the instruments, of naval warfare; but not once have they revolutionized it. The student of naval history will find that these predictions have come mainly and almost exclusively from the pen of the layman. Rarely is it that the professional mind leaps to extravagant and over-hasty conclusions of this kind. Occasionally it does, and for proof of it we have only to bear in mind the recent pronouncements of Admirals Sir Percy Scott and Lord Fisher.

Just now we are beginning to hear about the great possibilities of distant radio control of naval weapons which hitherto have required direct manual control. Experimental work carried on during the war proved that such control is possible, under favorable conditions, to an extent which before the war would have been scouted as quite impossible. Thus, it was shown that an airplane could be loaded with high explosives, sent up into the air without any pilot aboard, and directed by means of a new radio-control system installed on a pilot machine. It was proved that this controlled machine with its high explosive charge could be flown in the desired direction and made to strike unerringly any desired objective.

In other experimental work, carried out, like that to which we have just referred, under government auspices, it was proved that a torpedo may be steered into contact with its objective by means of radial impulses sent from an observing pilot plane flying overhead. Doubtless in the recent bombing of the old battleship "Indiana," use was made, if not of the same electrical appliances, at least of the same general principle. In this case, the "Indiana," without a single man aboard, steaming at ten knots was steered through radio control from the U. S. S. "Ohio," which maintained a distance of about five miles from the moving target.

It is too early to predict to what extent radio control can be substituted for manual control in aiming and firing the tremendous weapons which modern invention has placed at our disposal. If, for instance, the course of a torpedo can be controlled from an airplane and further experimental work fulfils the promise that is contained in this new method, we shall come nearer to revolutionary changes than ever before. This efficiency under war conditions, however, has yet to be proved.

## Electricity

**Electrically Deposited Thermocouples.**—A method of constructing thermocouples in which one of the elements is deposited electrically on a core, which constitutes the other element of the couple, is described in a recent issue of the London *Engineer*. In particular the couples investigated are those in which constantan is used with either silver or copper.

**An Arc Splitter** to lengthen the life of contactor tips has just been developed by a leading electric company. It consists of a refractory element which is so placed in the arc box of the magnetic blow-out as to project into the path of the arc, thereby forcing the arc to pass around it and thus increasing its resistance, causing it to rupture more rapidly. The arc splitter is immediately above the contactor tips.

**Alternating or Direct Current Bell.**—There has been developed an electric bell which operates equally well on alternating and direct current circuits of the proper voltage. The bell is designed so that the speed of the hammer is independent of the frequency of the current. A new principle in bell construction is used, consisting of a buckled steel spring coupled to the armature so that each stroke is very positive in action. The coil is wound on a laminated core and the hammer is under the gong.

**Carbon and Commutator Wear.**—It is said that although sparking voltages are the same in direct-current and alternating-current machines, the same sparking voltage may give widely different results under different conditions in either type of machine. Experiments are cited to show that the current density has an appreciable influence upon the arcing at the brushes. The influence of temperature and speed upon brush and commutator wear is also taken up in a recent issue of the *Journal* of the American Institute of Electrical Engineers.

**Defects in Lead Cables.**—While it is possible to detect the approximate location of a defect in a lead-covered cable, it is impossible to remedy the defect and recover the cable at that point without recovering the entire cable. It is sometimes necessary to strip the lead covering from a cable in order to reach a defect that has been discovered during a test, and make the necessary repair. Then the bare cable is again passed through the lead coating machine in order to replace its covering. This work necessarily involves a great expense, but it seems to be part of the business of making huge cables.

**A Double-Filament Lamp.**—Twice the life of the usual gas-filled lamp is the aim of a manufacturer who has recently introduced a double-filament lamp. This new lamp is placed in the ordinary socket in the same manner as the common type of lamp, and looks and operates in the same manner as the ordinary lamp up to the point where it burns out. Then the bulb is unscrewed from the socket, but, instead of throwing it away, a little cap is removed from the end of the base and the lamp is again put back into the socket. The removal of the little cap from the base brings the terminal of the second filament into place and allows the same lamp to be put back in service. Both the filaments are of equal wearing qualities.

**Has the Incandescent Lamp Limit Been Reached?**—Judging by the desire on the part of several incandescent lamp manufacturers to edge away from the one-half watt per candle-power rating of gas-filled tungsten lamps, it appears that we have been pushing tungsten filaments pretty hard. That is to say, we have about reached the absolute limit of tungsten filaments at one-half watt per candle-power rating, and if anything, we are too near the fusing point to make for good practice. It appears that greater efficiency with incandescent lamps can only be obtained if we discover some new filament material or a gas which is more suitable than nitrogen. Either of these possibilities seems remote.

**Color Screens for Window Lighting.**—A development that promises to be an outstanding feature in the practice of show-window lighting, and one that will have an influence upon every other branch of illuminating engineering, has recently made its appearance. Heretofore various devices have been resorted to for producing colored lighting effects, such as dipping the electric lamps in suitable dies, using sheets of colored glass, making the lamp bulbs of colored glass, and so on. But in every instance the heat of the lamp has ruined the colors. The latest device, which is reported to be a complete success, consists of a metal frame supporting a slide of colored gelatine which is held in place by a fine steel mesh. The slide slips in the frame and the latter, in turn, fits over the lamp reflector. In this manner the colors may be readily changed by inserting the desired slide. The colored gelatine holds its color remarkably well and is non-inflammable.

## Science

**Tree Rings and Climatic Fluctuations.**—For nearly twenty years Prof. E. A. Douglass has been studying the annual rings of trees, as found in various parts of the world, in quest of information concerning the history of climates. A complete account of his studies and their results is set forth in Publication 289 of the Carnegie Institution of Washington, "Climatic Cycles and Tree-Growth." Professor Douglass began with investigations on yellow pine in Arizona. By comparison with meteorological records he established the fact that the thickness of the annual rings seen in cross sections of the trees varied with the yearly rainfall. Having determined this relation for the comparatively brief period for which weather records were available he argued that the relation held good for earlier periods, and that sections of old trees would therefore furnish a record of fluctuations of rainfall for hundreds of years. His plan has been to study a group of trees of various species, appropriately located, for each region embraced in his investigations, and he has worked out some ingenious methods and mechanical devices for making his analyses and determining periodicities, etc. Sections were obtained from many parts of the United States and Europe, and, in the case of the *Sequoias* of California, the record has been extended back more than 3,000 years. Among the interesting discoveries announced by Professor Douglass is the fact that practically all the groups of trees investigated show the sunspot cycle or its multiples. There is also found a complex combination of other cycles, including a prominent cycle of about 2 years.

**Duration of Thunder.**—It is impossible to assign any theoretical limit to the duration of continuous thunder since the sounds of many successive lightning discharges may rumble so long as to merge into one another. In some cases the noise of wind and rain, accompanying the thunderstorm, may be so mingled with the thunder as to help produce the effect of a continuous rumble. The chief factor in the prolongation of a peal of thunder is the difference of time required for the sound to travel to the observer from different points along the path of discharge, which may be a mile, or perhaps several miles, in length. Under some conditions reflection of the sound from clouds, hills, etc., further prolongs the peal. But the Indian thunderstorms are notoriously violent, though comparatively harmless. According to Mountstuart Elphinstone, the setting-in of the monsoon in India is accompanied by such an electric convulsion "as can scarcely be imagined by those who have only seen that phenomenon in a temperate climate. It generally begins with violent blasts of wind, which are succeeded by floods of rain. For some hours lightning is seen almost without intermission; sometimes it only illuminates the sky and shows the clouds near the horizon; at others it discovers the distant hills, and again leaves all in darkness, when in an instant it reappears in vivid and successive flashes, and exhibits the nearest objects in all the brightness of day. During all this time the distant thunder never ceases to roll, and is only silenced by some nearer peal, which bursts on the ear with such a sudden and tremendous crash as can scarcely fail to strike the most insensible heart with awe."

**The Water-Supply of Armies.**—In a recent lecture by Lieut.-Gen. Sir Thomas Goodwin, K.C.B., of the British Army medical service, on the remarkable progress made in many lines of military hygiene during the war, much novel information was presented concerning methods of purifying the water-supply. Before the war dependence had been placed largely on the use of filter-candles, but they proved unsuitable for active service conditions and were replaced by chlorination. Chloride of lime in the form of bleaching powder was used throughout the war as the means of dealing with all water-supply, either in bulk, as in the big "water-points," or on a smaller scale. Special water-tank companies were eventually organized. These units were able to collect, filter under pressure through sand, sterilize by chlorine gas by means of an ingenious regulator, and transport large quantities of water wherever the motor-lorry could move. Along waterways barges were used for the same purpose. Any flavor of chlorine was removed by a "dechlorinating" process with sulfur dioxide gas. The new water units were also effective in testing water for mineral poisons. The success of water chlorination in the field led to its application to the municipal water-supplies at Boulogne and Rouen. The Americans adopted a similar scheme in some of the larger French towns occupied by their troops. General Goodwin points out that a result of the war has been the recognition of the sanitary service of the army as an organized department, and has aroused general interest in preventive medicine on the part of civilians.

## Naval and Merchant Marine

**Fate of the "Leviathan".**—Admiral Benson, being questioned as to the use to which the "Leviathan" is to be put, admitted that the situaion was a very trying one. He stated that it was difficult for any one firm, in the present state of the money market, to raise the necessary funds to buy the ship and recondition her. The United States Mail Steamship Company made an offer of three million dollars, provided the Shipping Board would make a loan of six million dollars to the company for reconditioning. Another condition of the offer was of 25 per cent of the net earnings of the vessel to the Board for ten years. Admiral Benson stated that personally he felt inclined to accept this offer.

**American Shipping in Our Carrying Trade.**—A recent United States Shipping Board survey of vessels entering and clearing in the foreign trade with cargo for the first six months of 1920 shows that a total of 15,558 vessels of 86,931,700 deadweight tons have entered and cleared U. S. ports in the six months ending June 30th, carrying 37,398,184 long tons of cargo. Vessels under American registry to the number of 9,550 (61.4 per cent of the total vessels) aggregating 51,534,620 deadweight tons (59.3 per cent of the total tonnage) carried 22,724,217 long tons of cargo (60.8 per cent of the total cargo carried). The American vessels carried 44.1 per cent of capacity load and the foreign vessels 41.5 per cent; the average for all flags being 43 per cent of capacity.

**Economy of Electric Drive.**—In a paper before the Institute of Marine Engineers, Captain W. P. Durtnall gives some authentic figures showing the relative economy of the reciprocating engine, of the electric drive and of the geared drive. These figures were estimated by the operating engineers of the "Florida" and "Utah," fitted with Parsons turbines, the "Delaware," with reciprocating engines and the "New Mexico," with the electric drive. The relative steam consumption per effective horse-power hour at twelve knots was for the "Florida," 31.8; the "Utah," 28.7; the "Delaware," 21.0; the "New Mexico," 17.3. At twenty-one knots the relative figures given are: "Florida," 13.0; the "Utah," 21.0; the "Delaware," 21.0; and the "New Mexico," 16.4.

**Activities of the Shipping Board.**—Shipping Board vessels carried during the last fiscal year a total trade of 20,615,402 tons, which passed in and out through 49 United States ports. That there is a marked concentration of this carrying trade is shown by the fact that 26 of the 49 ports handled over 90 per cent of the entire tonnage moved. New York stands first with 27.9 per cent, and Baltimore and Philadelphia next, each with 10 per cent. Next in order comes a southern port, New Orleans, which carried 7.6 per cent, then Norfolk with 7.1 per cent, and San Francisco with 5.1 per cent. A study of these figures shows a remarkable concentration of maritime traffic on the eastern seaboard of the country. The chairman has stated that it would be his policy to bring about a more widely extended distribution.

**Ships That Carry the 16-Inch Gun.**—We have ten battleships under construction which will carry the 16-inch gun. Of these, four, the "Colorado," the "Maryland," the "Washington" and the "West Virginia" will mount eight 16-in guns, and the "Indiana," the "Iowa," the "Massachusetts," the "Montana," the "North Carolina" and the "South Dakota" will each mount twelve 16-inch guns. In this connection we wish to correct a statement in an article, "Our Naval Standing," which appeared in the SCIENTIFIC AMERICAN of June 26th, where the "California" and the "Tennessee" are each credited with mounting eight 16-inch guns. As a matter of fact, these ships each mount twelve 14-inch guns. There was some discussion of the advisability of giving them eight 16-inch guns when the 16-inch gun, after proof, showed its excellent qualities, but nothing came of it.

**The Fate of the Surrendered German Ships.**—The ships that formed the remainder of our share of the surrendered German fleet, consisting of the battleship "Ostfriesland," the scout cruiser "Frankfort," three three destroyers and a few submarines will not be incorporated in the active navy of the United States. The "Ostfriesland," the most important of the surrendered ships, was ninth in line at the battle of Jutland. She received no great hurt in that battle but was seriously injured by contact with a mine during the flight of the German fleet in the early morning following the battle. The "Frankfort," a fast cruiser, was actively engaged in the war, especially at Jutland. There are also three destroyers, the G-102, which is somewhat larger than any destroyer of our Navy, the S-132, of about 600 tons, and the B-33. Ultimately, the "Ostfriesland" will be used as a target.

# The Problems of Electrification

## The Struggle Toward a Standard, and What Is Likely to Come of It

By Robert G. Skerrett

**The electric locomotive demonstrating its greater economy and efficiency in terminal yards**

ACCORDING to the latest official figures, we have upon our 230,000 miles of steam lines a matter of substantially 2,500,000 freight cars and quite 30,000 freight locomotives, not to mention 15,000 engines at terminals for switching service. Offhand, this array of rolling stock might seem ample for our needs, but an analysis of what it has been doing recently will make it clear that there is something radically faulty in performance, especially in view of the many million tons of goods of all sorts that are cluttering stations and warehouses awaiting much-delayed distribution. To be specific: the final report of the United States Railroad Administration reveals that the average miles per freight car per day were about 22; that each loaded car carried as a rule something less than 30 tons; and that fully one-third of the car miles was run without lading. Finally, we find that each freight engine made an average of approximately but 60 miles every twenty-four hours.

One does not have to be versed in higher mathematics to realize that there is a tremendous lack of service or wastage under existing conditions. Why is this the case? What is the logical relief? It is not necessary to reiterate in detail the multiple operative shortcomings of the steam locomotive, but let us sum up a few of them. It seems that one-quarter of the coal mined annually in this country and six per cent of our fuel oil is consumed by the steam engines of our railways, and a good third of those combustibles is sacrificed in what are termed "stand-by losses." Aside from that, the fuel is inefficiently utilized when the locomotives are actually doing work. Further, the distribution of coal for our trunk lines requires a tonnage movement amounting to approximately 20 per cent of the total freight-ton miles that should yield revenue. This is not hard to understand if we recall the fact that there is first the transportation of the fuel from the mine to the coaling station, then its wanderings on the engine tender, and next the trip of the empty coal car back to the colliery. It is authoritatively declared that the tenders of our steam locomotives of all kinds add about 11 per cent to the ton mileage of our roads without bringing in a return.

Plainly, to just the extent in which we may find a way to reduce the ton mileage of railway coal or oil we shall be able to utilize the cars so freed for the carriage of other essential freight. In 1918, our steam lines burned 163,000,000 tons of coal and 45,700,000 barrels of oil. According to Government data, counting an average load of 30 tons, 5,677,000 car trips were needed to deliver the fuel during that year. This arraignment of the steam locomotive would be incomplete if we failed to take into account the handicaps imposed by seasonal and atmospheric conditions as well as the steam tractor's inadequacy when it comes both to mounting and to descending steep grades with heavy trailing loads.

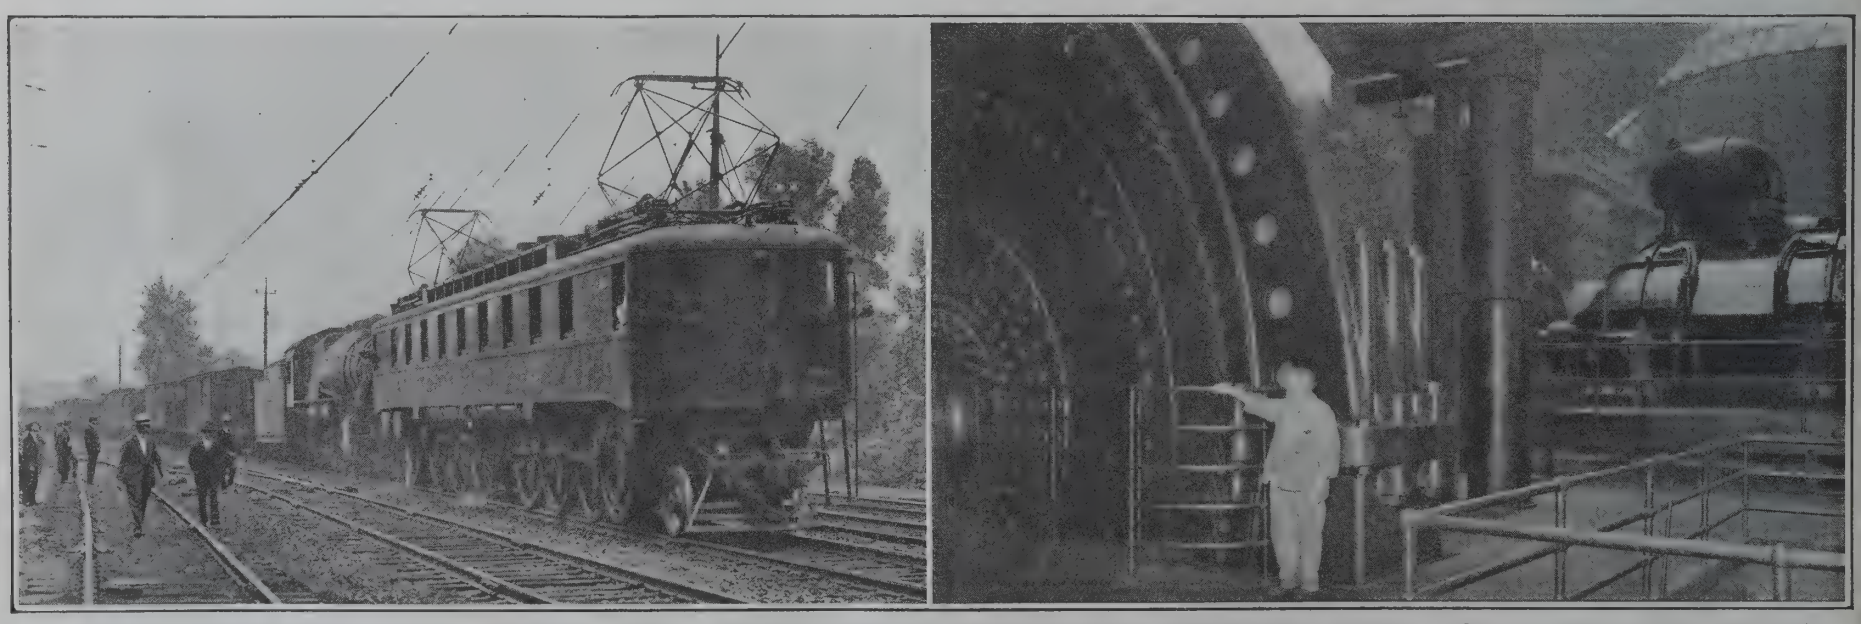
Anyone with a moderate knowledge of the physical geography of the United States must be alive to the fact that the mountainous nature of many sections interferes greatly with rapid movement on the part of both passenger and freight service, but much more so in the case of freight trains. Because of numerous heavy gradients, engineering difficulties, and the expense entailed, the mountain routes are frequently single-track lines and seldom more than double track. Thus, the tide of traffic is slowed down and passed through constricted channels. This would not be so bad if the steam engine could maintain a higher speed when climbing and descending these slopes, but unfortunately the steam locomotive cannot do this. It must materially reduce its load when going up hill in order to pull the train along and, because of its deficient grip upon the rails it often cannot hold safely back the same number of laden cars when sweeping down the opposite incline.

Therefore, we have a reversal of the very action upon which we normally count when we seek to shift from one reservoir to another a given fluid volume by means of a relatively small connecting conduit. That is to say, just where increased velocity is essential on our railways we cannot have it. Every now and then some of our steam roads—and these frequently among our most important trunk lines—have to contend with this bottle-necking, and it is at these points or along these sections that the freight movement is throttled.

The apparent solution of the problem, which is becoming more and more acute from year to year, is the substitution of electric traction. Out west one transcontinental road is pulling trains of 4,000 tons up and down steep mountain slopes and exercising perfect control the while. It is doing this at speeds hitherto unattained under like circumstances, and the schedule is being maintained with remarkable regularity. Not only that, but the oper-

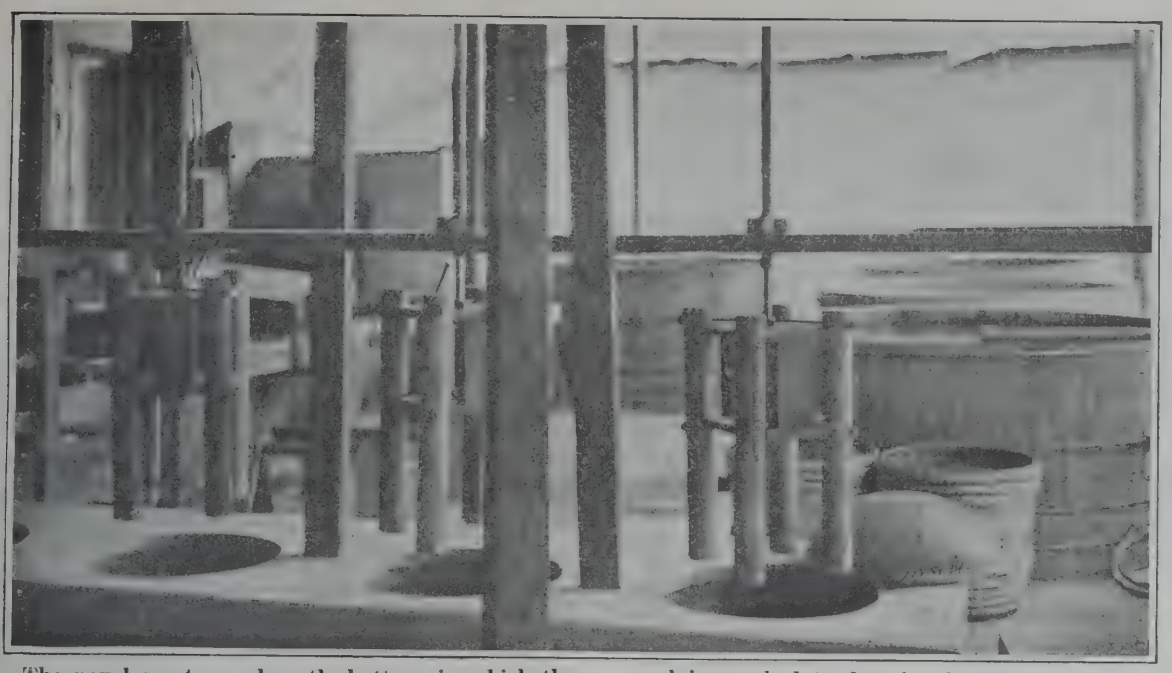
(*Continued on page 457*)

*TO tell the average American that we have outgrown steam traction will probably shock him as he casually judges the apparent efficiency of the speeding express, or comes upon an occasional freight train in the course of his daily habit of life. Yet the fact remains that such is the status of our land transportation system when the aggregate movement of cars and tonnage is considered. Our national well-being is contingent upon an improvement in this matter; and it appears that improvement is possible only through the substitution of electricity for steam as a motive power. Mr. Skerrett tells us in this article something of the manner in which this substitution must be effected.*—THE EDITOR.



*Left:* A powerful electric locomotive of special design that has saved the day in speeding up freight traffic on one trunk line. *Right:* In the foreground a big dynamo driven by reciprocating engine; in the middle distance a steam turbo-generator set of like power, much higher efficiency, and far less bulk. Where fuel must be employed for the generation of current, it is units of the latter type that will be relied on in large railroad central stations

**Typical units that are making electrification of our railroads a success**



The novel mortar-and-pestle battery in which the seaweed is crushed to free it of clinging shells, sand and alkali

Agar-agar—the finished article in silvery sheaves of an average weight of three pounds each

## California's Seaweed Industry

By John L. Von Blon

AGAR-AGAR, that valuable aid to medical science and important food adjunct for the supply of which the world heretofore has relied solely upon the Orient, is about to be extensively manufactured in the United States. An American company already is turning out a third of a ton daily in a finely-equipped plant at Glendale, a suburb of Los Angeles, California, and steadily will increase its capacity. Thirty-five thousand dollars' worth of specially-designed machinery has been installed in an artistic concrete building having 15,000 square feet of floor space and a five-acre surrounding lot which also is utilized. This marks the establishment of a new industry with great possibilities, or rather the transplanting of an old one to virgin soil. And it is an interesting progressive departure inasmuch as only crude mechanical appliances are used in the Far East.

Japan has enjoyed a monopoly in agar-agar, and last year this country imported 240 tons, of approximately half a million dollars' worth from there, and Great Britain and other European countries much more. Consumption is heavily increasing although the public generally never has heard the name. It is a gelatin-like derivative of seaweeds and meets wants which nothing else can. In Japan but ten species of the marine algae required are found. Two years' diligent research disclosed that fifteen species of superior quality grow in comparative abundance along the southern California coast. The Glendale factory is the result. There it is demonstrated that the American finished article far excels the hand-made oriental product. In their eagerness to increase their profits the Japanese mixed plants other than algae with seaweeds and thus imposed upon the entire world. One of the large eastern pharmaceutical manufacturing concerns is negotiating for the whole California output, and the War Department also is looking to that end. A certain prepared package of agar-agar weighing eight ounces sells for about a dollar.

"Kanten," as the Japanese call agar-agar, long has been esteemed there as a food, and as such it appeals more and more everywhere. It is a wholesome and delicious thickener in jellies of all sorts, fruit, meat or fish. It is particularly beneficial mixed with any ordinary cereal or breakfast foods with the addition of sugar or salt. In candy making, too, this strange gift of the ocean is a factor. It goes far and a pound is sufficient to supply an ordinary family for many months; but the price has jumped from 50 cents to $1.25 and over during the emergency of the past few years.

The major demand is from hospitals, laboratories and the medical profession. The peculiar substance has no equal as a culture media for bacteria, retaining its solidity, unlike gelatin, at the requisite temperatures, and thus proving indispensable to bacteriological research and segregation. During the war it figured successfully in the healing of certain wounds. It has the natural property of absorbing water and retaining it; and, in medicine, the additional property of resisting the action of intestinal bacteria and of the digestive enzymes. It is employed as a mechanical stimulant or alterative to overcome constipation without the violent action characteristic of effective cathartics. It has no inherent flavor, little nourishing power, and doesn't digest. It promises to displace many drugs which leave harmful after-effects.

Those seaweeds constituting the basis of agar-agar are prolific off Cayucos, San Luis Obispo, Santa Barbara, Los Angeles, Oceanside and down along Lower California. Among others are *Geldium corneum* and *cartilagineum*, *Gracellaria confervoides*, *Euchema spinosium*, and various forms of *Tenax* and *Gigarteneae*. The leaves, dainty and beautiful, brilliant red, purple, pink, yellow, white or black, are hunted on the beaches by tourists and pressed and treasured as "sea moss." The plants grow only on rocks and as a rule where they can be gathered at low tide, though in some localities expert divers get the best. Off California they attain a height of two feet and are slightly coarse. In Japan, stunted by 250 years of picking, half that size is the maximum. The average worker on fairly good "ground" can harvest 200 (dried) weed, or one bag per day, and for this he is paid $20 f.o.b. Glendale—10 cents a pound. To get 200 pounds of dry weed he must pick 600 pounds wet. It is pulled up with the hands. Most of the supply comes from fishermen under contract, and American labor is so high that they find it more profitable to carry the algæ up from Mexico, where four boat crews now are working.

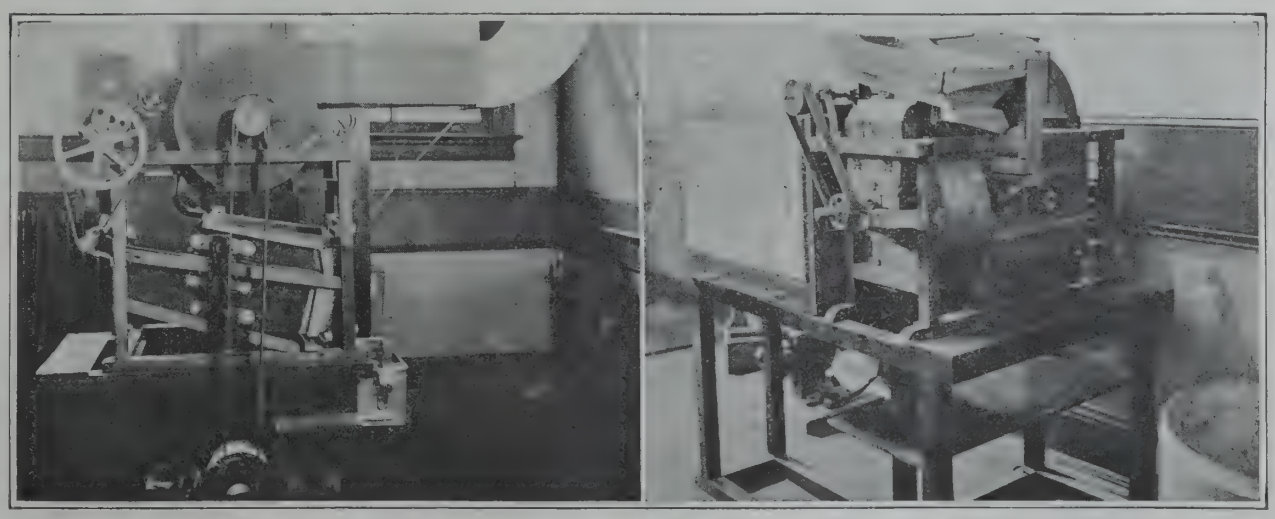
(*Continued on page 458*)

## Setting Federal Wheat Standards

By George H. Dacy

IN order to evolve grain-grading standards of general application and satisfaction, the scientists of the Federal farming forces at Washington are now utilizing a minature flour-milling plant and bakery in order to test out all of the varieties of wheat grown in this country and to ascertain definitely their intrinsic value as measured in terms of the size and quality of the loaves which they produce. The small scale testing plant is outfitted as far as possible as an exact replica of a large commercial mill. Its equipment includes two grain separators and a scouring machine which remove foreign matter from the wheat and prepare it for tempering and milling. The mill proper, which is of the non-automatic type, consists of four single stands of six-by-six-inch rolls, three of which are corrugated while the other is smooth. It is operated in such a manner that it practically duplicates the flow of a five-break, nine-reduction roller mill such as is largely used commercially.

After the samples of wheat have been graded according to the Federal standards now in effect, the grain is cleaned and then passes through the mill which converts the kernels into flour. The flour is stored for a few days and then is made into dough and baked into bread in the miniature bake-shop which is operated in conjunction with the flour mill. The bakery is equipped with a modern electric baking-oven, an up-to-date dough-mixing outfit and a sponging cabinet heated by electricity where the dough is placed for rising. After each sample of flour is converted into bread, the latter product is examined carefully as to color, texture, flavor of the bread and expansion of the loaf, these data being of value in checking up the baking qualities of the flour as compared with its milling merits. All this information is useful in checking up the grain-grading records of the various samples of wheat tested. Every variety of wheat in the country—of which there are over 150 different kinds—will be tested out by Uncle Sam's scientific experts and the results of these investigations will be of ultimate and future value to every bread consumer in the entire country.



The receiving separator that cleans out the weed-seed, chaff, straw and other foreign matter from the grain.

The scouring machine that eliminates the smut, beards, and other material that cling to the bran.

**Accessories of Uncle Sam's miniature mill and bakery that are employed in standardizing grain tests**

## Nickel Babbitt

FOUNDRY, in answer to a question states that many so-called nickel babbitts contain no nickel, but that a nickel babbitt can be made containing 4 per cent of copper, ½ per cent nickel, 10 per cent antimony, and 85½ per cent tin. The copper and nickel are charged together and covered with charcoal. Antimony is added gradually, and then the tin.

# Edison's Views on Life and Death

## An Interview with the Famous Inventor Regarding His Attempt to Communicate with the Next World

As Reported by Austin C. Lescarboura

*WHEN a man of the standing and personality of a Lodge or an Edison interests himself in a subject, the public is never cold to the announcement of what he is doing and what he hopes to accomplish. So when the news went out, the other day, that Edison was carrying on experiments looking toward communication with the dead, the newspapers gave the item a place out of all proportion to that which its intrinsic importance in the scientific progress of the day and the stage to which Edison's work has progressed would have entitled it. In this they were quite right, because their readers were interested in the bare news that Edison was working on the problem. We believe that our readers, too, are interested in what Edison is doing in this field and what he has to say about his theories and his work. Hence this interview, in which Mr. Edison, himself, tells us what he believes about survival and why he hopes to establish communication. And if one thing stands out clearly beyond all other things in this interview, it is that regardless of the manner in which sensational newspaper stories may present the matter, Edison stands for a return to sanity in our attitude toward the possibility of survival of personality and communication with those who may have survived.*—THE EDITOR.

EDISON—the man who has given us the electric light, the phonograph, the motion picture, the nickel-iron storage battery, the perfected dynamo and a vast collection of other devices entering into our everyday life—is about to devote himself to something which is infinitely more interesting than any invention can ever be. Here we are, something like one billion five hundred million human beings, facing death sooner or later yet totally ignorant of what is to become of our personalities. And the same can be said about our coming into this world, for life and death remain the greatest mysteries of the ages.

Several weeks ago the word was passed around to the effect that the great inventor was working on a device, or apparatus as he prefers to term it, to communicate with personalities which have passed on to another existence or sphere. Immediately the press of the United States and Europe announced that Thomas A. Edison had joined the ranks of the spiritists, which now number many a prominent scientist, author, inventor, physicist, engineer, clergyman, and so on. Soon the highly imaginative French writers drew pen pictures of Mr. Edison's apparatus serving as a telephone station or telegraph office or whatnot, where persons wishing to communicate with those who have passed on could do so in a positive and prompt manner.

And no one is more sorry than Mr. Edison that this impression has been permitted to gain ground both here and abroad. "In the first place, I cannot conceive such a thing as a spirit," said Mr. Edison to the writer. He meant it, too. "Imagine something which has no weight, no material form, no mass; in a word, imagine nothing! I cannot be a party to the belief that spirits exist and can be seen under certain circumstances and can be made to tilt tables and rap and do other things of a similar unimportant nature. The whole thing is so absurd."

In fact, it was mainly for the reason of correcting the impression about Mr. Edison's activities in this latest field of research that the inventor granted the writer an interview. The apparatus which he is reported to be building is still in the experimental stage. Obviously, Mr. Edison is too cautious and too well founded in the uncertainties of any new experimental work to say anything definite at the present time. However, he wishes to say the following, which is very significant in the light of his past record in so many fields of endeavor:

"I have been thinking for some time of a machine or apparatus which could be operated by personalities which have passed on to another existence or sphere. Now follow me carefully; I don't claim that our personalities pass on to another existence or sphere. I don't claim anything because I don't know anything about the subject. For that matter, no human being knows. But I do claim that it is possible to construct an apparatus which will be so delicate that if there are personalities in another existence or sphere who wish to get in touch with us in this existence or sphere, this apparatus will at least give them a better opportunity to express themselves than the tilting tables and raps and ouija boards and mediums and the other crude methods now purported to be the only means of communication.

"In truth, it is the crudeness of the present methods that makes me doubt the authenticity of purported communications with deceased persons. Why should personalities in another existence or sphere waste their time working a little triangular piece of wood over a board with certain lettering on it? Why should such personalities play pranks with a table? The whole business seems so childish to me that I frankly cannot give it my serious consideration. I believe that if we are to make any real progress in psychic investigation, we must do it with scientific apparatus and in a scientific manner, just as we do in medicine, electricity, chemistry, and other fields.

"Now what I purpose to do is to furnish psychic investigators with an apparatus which will give a scientific aspect to their work. This apparatus, let me explain, is in the nature of a valve, so to speak. That is to say, the slightest conceivable effort is made to exert many times its initial power for indicative purposes. It is similar to a modern power house, where man, with his relatively puny one-eighth horse-power, turns a valve which starts a 50,000-horse-power steam turbine. My apparatus is along those lines, in that the slightest effort which it intercepts will be magnified many times so as to give us whatever form of record we desire for the purpose of investigation. Beyond that I don't care to say anything further regarding its nature. I have been working out the details for some time; indeed, a collaborator in this work died only the other day. In that he knew exactly what I am after in this work, I believe he ought to be the first to use it if he is able to do so. Of course, don't forget that I am making no claims for the survival of personality; I am not promising communication with those who have passed out of this life. I merely state that I am giving the psychic investigators an apparatus which may help them in their work, just as optical experts have given the microscope to the medical world. And if this apparatus fails to reveal anything of exceptional interest, I am afraid that I shall have lost all faith in the survival of personality as we know it in this existence."

Mr. Edison does not believe in the present theories of life and death. Long ago he turned his back on the various old and accepted theories because he felt that they were fundamentally wrong. And just as he experimented with one substance after another without ever becoming discouraged in his search for the filament of the first successful incandescent electric lamp, so he has searched and reasoned and built up a structure which represents his theories of what is life.

"I believe that life, like matter, is indestructible," began Mr. Edison, in outlining his theory of life and death. "There has always been a certain amount of life on this world and there will always be the same amount. You cannot create life; you cannot destroy life; you cannot multiply life.

"I believe our bodies are composed of myriads and myriads of infinitesimal entities, each in itself a unit of life, which band together to build a man. We have taken it for granted that each of us is a unit. We think of a cat, an elephant, a horse, a fish and so on as units. I am convinced that such thinking is basically wrong. All these things appear to be units only for the reason that the life entities of which I speak are far too small to be detected even with the ultra-microscope.

"The question has been raised that if these life entities are so small, they cannot be large enough to include a collection of organs capable of carrying on the tasks which I am about to mention. Yet why not? There is no limit to the smallness of things, just as there is no limit as to largeness. The electron theory gives us a reply which is wholly satisfactory. I have had the matter roughly calculated and have at hand the data of the calculation. I am sure that a highly organized entity, consisting of millions of electrons yet still remaining too small to be visible through any existing microscope, is possible.

"There are many indications that we human beings act as a community or ensemble rather than as units. That is why I believe that each of us comprises mil-

## Record Weather

To the Editor of the SCIENTIFIC AMERICAN:

In an article in your columns a year or more ago it was stated that a record of temperature by the United States Weather Bureau station at Greenland Ranch, on the border of Death Valley, showed 134° in the shade. In the article "Record Weather" in your issue of August 21st the mark is set much lower than that. It is regrettable to have such discrepancies creep in, for an error in the figure that one happens to know about tends to cast suspicion on all the other figures that one does not know about. A. I. LOOP.

North East, Pa.

To the Editor of the SCIENTIFIC AMERICAN:

In your issue of August 21st it is stated that Fort McDowell, Ariz., holds the record for heat in this country, with a maximum of 119° Fahrenheit, and that the highest known temperature is reported from Algeria at 127.4°. A brief search of the records from 1897 to 1908 discloses seventy-seven records of 120° or more from stations in southeastern California and southwestern Arizona, culminating with 128° at Volcan Springs, Cal., July 9th, 1905, and 129° in the same place June 23rd, 1902. It might also be of interest that temperatures of 110° and more are frequently recorded at Yuma, though this is by no means the hottest station in the region. At Aztec, Ariz., in July, 1905, the average daily maximum for the month reached the astounding figure of 117.9°. H. A. GLEASON.

New York City.

To the Editor of the SCIENTIFIC AMERICAN:

I notice in the issue of August 21st the statement that Cherra Punji, India, has the heaviest rainfall in the world. Sometime ago you published the statement that a spot in the Hawaiian Islands had been found with a heavier rainfall. Which is correct?

Cleveland, Ohio. HERBERT W. ROSS.

To the Editor of the SCIENTIFIC AMERICAN:

In reply to the criticisms called forth by my article "Record Weather," I am afraid I must plead guilty so far as the Greenland Ranch high temperature record is concerned. This record was made on July 10th, 1913, by a fully authenticated instrument, and stands as the highest official mark for this country or any other. I do not yet understand how I missed this, as it was among the Weather Bureau records that were placed at my disposal during the preparation of the article.

As regards the balance of the article, I may say that the Weather Bureau, which receives and files the SCIENTIFIC AMERICAN each week, has filed this copy with two corrections in my article—this one, and another making the West Indian hurricanes occur "usually" between June and October, instead of "always" during this interval, as I had it. Aside from these two items, the Weather Bureau has no exception to take to my article, and I am sure will inform you to this effect if you inquire of them.

While it is true that every statement in the article with these exceptions is true so far as official records go, it is of course equally true that many readings higher than the highest official one and lower than the lowest official one are on record. We all know that the thermometers used by the Weather Bureau are the only ones recognized as accurate, especially in the recording of extremes. At times thermometers will vary by as much as five to eight degrees when hanging side by side. It seems a bit rough to throw out a record which may be perfectly all right, on the mere ground that the thermometer was not properly verified, but the same thing happens in other matters of record every day, and there is really no other help for it. The Hawaiian rainfall record is another case of the same sort. I have no doubt that it occurred substantially as reported, but it is not official and that is all that can be said on the matter.

I may say that there have been recorded, so recently that they are now on the files of the Weather Bureau but were not there when I compiled my article, new world extremes at both ends of the temperature scale. One of these, from Africa, raises the Greenland Ranch record a fraction of a degree; the other, from Western Canada, lowers the extreme mark of officially observed cold to the same extent.

Washington, D. C. WENDELL WHITING.

To the Editor of the SCIENTIFIC AMERICAN:

Referring to your recent paper on Record Weather, the Weather Bureau publishes daily precipitation reports but they do not seem to record what is just as important, particularly just now in California, the daily evaporation per square mile. This would apparently give an indication of climate useful to the farmer and to certain industries.

Vallejo, Cal. C. E. BURNLEY.

## The Time-Space Manifold

To the Editor of the SCIENTIFIC AMERICAN:

The time-space concept clarifies our idea of time which may be defined as a fiction of the finite and three-dimensionally-conditioned intellect, devised to differentiate, locate and dislocate events in the cosmic change and experience. Time is linear and directed; it is therefore reëntrant, an infinity of time being circular and returning upon itself. I infer that hyper-dimensional time possesses qualities of superficiality, such as spreading or stretching; a hyper-dimensional (4 or "n") time-infinity is spherical in three-space and dislocated events or changes in three-space are hyper-dimensionally synchronous.

New York. ALBERT R. GALLATIN.

## The Air Service Corrects Us

To the Editor of the SCIENTIFIC AMERICAN:

On page 253 of the SCIENTIFIC AMERICAN for September 11th, 1920, it is stated that, "the Verville-Packard airplane was designed and built by the Packard Motor Car Company under the guidance of Col. J. G. Vincent." This statement is entirely incorrect, since the Packard Motor Car Company had no part in the design or construction of the airplane, their share in the development being confined solely to the engine. The Engineering Division of the Air Service at McCook Field designed and constructed the Air Service entry entirely in their own shops. The designation is not "Verville-Packard," but should be, "Engineering Division Model V.C.P.R."

In the same issue on page 251 under the title "Making Doubly Sure of the Parachute Jump" occurs the sentence, "If one parachute fails to open, which sometimes happens, the other by all the rules of probability should open." This sentence gives the impression that Air Service parachutes occasionally fail to function. It may be stated unequivocally, that the Air Service parachutes have never failed to open successfully, although an instance is on record where a civilian jumper, in testing a parachute built by a private concern, was saved from certain death by the fact of his having an Air Service standard parachute in reserve.

McCook Field. THURMAN H. BANE,
Major, A. S.

## American Engines

To the Editor of the SCIENTIFIC AMERICAN:

In the September 4th issue of your magazine one of your correspondents makes a statement to the effect that as engine designers the Americans excel all others. A statement of that kind is gross error and calls for criticism.

There are a few things that we Americans should know. We should know that Europe, especially Germany, has developed engines far more efficient than our own. Mr. G. F. Gebhardt, in his *Steam Power Plant Engineering*, says that while the average American 40-horse-power plant has an efficiency of seven per cent, in Germany it runs anywhere between twelve and fourteen per cent. Another thing that we should remember is this: The best American flying machine with two motors, 400 horse-power each, can carry 800 pounds, using fifty-six gallons of fuel to the hour; while a German machine, with a 160 horse-power motor, can carry 1,000 pounds, using seven gallons of fuel per hour!

I believe that no further proof is necessary to convince some of your engineers that there is much to be done before we can boast that we hold first place in engine design. N. T. PELFF.

University of Illinois.

## The Dairy Problem

To the Editor of the SCIENTIFIC AMERICAN:

The dairy presents some peculiar and paradoxical problems. Milk production as a general thing must be followed by an entire community. There must be sufficient production to maintain a receiving station; the withdrawing of a few dairies may close a creamery or cheese factory and force others to abandon dairying.

Milk production and beef-raising are interwoven. About one-seventh of the dairy cows of this State are killed each year. Some of these are young animals that have proven poor producers but most of them are worn out and old. High prices and low prices for beef are equally disturbing: the former encourages the killing of producing cows, and the latter the retention of worn-out animals. Usually the beef value of a cow is only a fraction of the cost of raising her. About three-eighths of a cow's life is unprofitable. The first two years are without any production whatever; the next two are below par, and there is a rest period of about two months each year.

A few years ago much of the milk produced in this State was used in the production of butter. The skim milk was fed to hogs. At present much of the milk is used in liquid form. Where it is skimmed for the cream the skim milk is made into cheese. This means less pork and more cheese. The food value of the cheese from a given quantity of skim milk exceeds the value of the pork.

Jefferson, N. Y. R. C. JONES.

## Caring for the Cone Clutch

To the Editor of the SCIENTIFIC AMERICAN:

On page 297 of your September 25th, 1920, issue you explain partly why a cone clutch becomes harsh, and some of the remedies.

I would like to add that the reason the smooth hard clutch is harsh or "rank" is that it has no high spots to allow it to engage gradually, but on the contrary engages with all its surface and all its power at once or not at all.

The sponging and oiling process is all right but must be followed up by blocking out the clutch when not in use, otherwise the leather is so compressed that it cannot absorb the oil and the effort is therefore wasted.

I would like to add that in my opinion ninety per cent of rear end trouble is directly caused by poorly constructed and poorly operated clutches and that the life of the car might be doubled and the upkeep expense materially lessened by more attention to the proper functioning of this important unit, not only by the designing engineer, but also by reasonable care on the part of the operator.

Hackensack, N. J. S. S. VAN DUSEN.

## Riding the Air in a Balloon Without a Basket

THE national balloon race which started from North Birmingham, Ala., on September 25th, brought out a spectacular feat which we believe gives the lie to the assertion that there is nothing new under the sun. One of the competing balloons, manned by Lieutenants Emerson and Sloman of the United States Navy, in passing over Kentucky was forced to do a good deal of vertical dodging of thunderstorms, its maneuvers including two landings. As a result so much gas was lost out of the big bag that it lacked sufficient lifting power to stay in the race under the usual conditions. The two lieutenants met this situation by cutting away the pilot's basket, and taking the air again, clinging to the balloon rigging above the concentration ring. As if this stunt were not in itself sufficiently perilous, the ingenious ballooners ran into further storms in the Lake Erie region, of such intensity as to render a final landing imperative. In order to effect this landing they had then to slit the fabric of the balloon. They finally came down in an Ohio hay field, after a flight of 37 hours 1 minute, of which 13 hours was without the basket. The distance covered from the starting point was 590 miles, and the extraordinary means employed to stay in the race resulted in the capture of third place by the daring improvisators. It may be remarked, further, that the final landing was made without injury to the operators or the remaining equipment. We hope that this stunt will not become standard practice, but in any event we feel that it well merits the place we have given it on our cover this week.

## A Call for Volunteers

VARIABLE star observing is a little known and yet highly important line of telescopic research work that is worthy of wider publicity, chiefly because it offers to the owner of a small telescope, say of three-inch aperture or larger, an opportunity to contribute observations of scientific value.

The American Association of Variable Star Observers was founded in 1911; it now has a membership of over two hundred, mostly amateurs. During the past nine years its members have contributed and published over 100,000 observations.

The dues of the Association are $2.00 per annum. A cordial invitation is extended to all interested in promoting the advance of astronomical knowledge to join its ranks. The work is entirely visual, not in the least difficult, involves no mathematics, and is of fascinating interest.

Further information and application blanks may be obtained by addressing the Secretary, W. T. Olcott, Norwich, Conn.

# Revising High Bridge

## Five Alternative Official Plans for Doing Away with the Piers that Obstruct Navigation

By W. B. West

THE general outlines of the situation presented by High Bridge, over the Harlem River about opposite West 174th Street, New York, are familiar enough to the readers of the SCIENTIFIC AMERICAN, but may bear a brief recapitulation. The bridge was built nearly three-quarters of a century ago, as a means of carrying the original Croton Aqueduct across the Harlem River; and in fact still forms a part of the water-supply system of the city, though no longer a part of first importance. As a natural consequence of its character, the bridge was built in the multiple-arch type, with five arches (four piers), making up the river span and in addition a number at the ends, especially the east end, to carry the rather high level of the structure back to the high but sloping bank.

**The scheme that stands out, architecturally, as fundamentally distinct from the other four, involving two new longer spans, each replacing two of the older and shorter ones**

**The most ambitious of the suggestions—a single long stone arch span to replace four of the present arches, leaving only one short arch over the river at the east (right) end**

At the time of its building the bridge was distinctly out in the country; and the Harlem River over which it stood was subject to little traffic, and that little largely for pleasure. With the growth of the city and the city's business, the establishment of great railroad terminals at the south end of the river, and the development of Erie Canal traffic, there grew up a very considerable congestion in the Hudson River and about the lower reaches of the Harlem—a congestion which was relieved by the construction of the Harlem River Ship Canal. This passage cuts through the low ridge of rock which separates the Hudson and Harlem River valleys at Spuyten Duyvil and Kingsbridge, and makes the Harlem what the present generation knows it for—less a true river than a strait, similar to the East River, and connecting the Hudson River with Long Island Sound and the great freight terminals of Mott Haven by a route that eliminates the long haul around the lower end of Manhattan Island.

As a consequence of all this, traffic on the Harlem River today is quite heavy, sufficiently so, in fact, to make the heavy stone arches of High Bridge a serious impediment. For the passageway allowed beneath these arches gives the big harbor barges a very small clearance, and it is not unusual for a tow to scrape more or less badly in getting through, while the treacherous currents set up by the very presence of the piers in the river now and then furnish the setting for a real wreck. The War Department, under its control of navigable streams, has long objected to the presence of these piers, but has never brought the matter to an issue. Now it has done so, however, and the city is faced with the alternative of removing or remodeling High Bridge.

**A triple-length span flanked at either end by one of the present arches**

**A single arch in the center of the river, replacing three adjoining units of the present bridge, and reducing the ones at either end to the level of mere ornaments**

**Another suggestion that would place the new triple span at the western side of the river, leaving two narrow arches over the water at the east**

Alike on account of its historic interest and the part which it plays in the water supply—a part small under normal conditions but which might become vital in the event of emergency affecting the deep tunnel from the Catskills — the consensus of opinion is that the bridge should be preserved if possible, and in a form as closely approximating its present one as may be. The additional argument is made that there is no other bridge over the Harlem River between Central Bridge at 155th Street and Washington Bridge at 181st Street, a distance of over a mile. The reason for this is that the streets of Manhattan are separated from the river, throughout this distance, by an upstanding ridge of rock which forms the backbone of Morningside Heights, St. Nicholas, Colonial and High Bridge Parks. Along this particular interval from Central to Washington Bridges the configuration of the ground is such that no effort has ever been made to carry the lateral streets down to the Harlem River; and even on the Bronx side the situation is similar though hardly so extreme. It is argued that in remodeling High Bridge it could be provided with an effective roadway, which it now lacks, and an effective connection with the street system at both ends, which it lacks at the Manhattan end, where only foot-passengers can now leave the bridge.

With the positive action of the War Department, and all these considerations favoring a revision rather than a removal of the bridge, a good many plans have been put forward for eliminating one or more of the stone piers in the river which now support the bridge. Official opinion on the subject, however, has been very slow to make itself heard; and the photographs which we publish herewith are in fact the first public expression of what the responsible members of the city's engineering organization think of the problem.

These pictures are all from the official file of the city's engineers. They are all got up in the same way, by removing from a photograph of the bridge as it now stands the arches whose removal the particular scheme in question contemplates, and drawing in, in their place, the features of the new plan. Of these new plans there are, as will be seen, five from which to choose.

## Getting a Line on Concrete Pipe

By S. R. Winters

WHEN 40 varieties of concrete pipe are being used for irrigation purposes, California alone supporting 150 concrete-pipe manufacturers, the demands for scientific information on the subject are not to be ignored. Strength, imperviousness to an incessant flow of water, and dependability are factors in an irrigation pipe system which insure the transformation of arid barrenness into flourishing areas of vegetation and people. The absence of these qualities may prove costly and retard man's progress in subduing an otherwise fertile territory.

Contractors, engineers, and irrigation managers are annually laying many hundred miles of artificial water routes, not without some trepidation, owing to the lack of specific information as to materials and methods entering into the manufacture of concrete pipe. Home-made equipment frequently isolated from the marts of trade, and a limited output are conditions which have heretofore kept standardization of the finished product in the background. Mounting prices of iron and steel, with a consequent enlarged use of concrete pipe in building irrigation routes, lend emphasis to the efforts of the Division of Irrigation of the U. S. Bureau of Public Roads in standardizing the methods of manufacture of the product.

Coöperating with the Department of Engineering of the State of California, the Federal government about twelve months ago established a field laboratory at Pasadena, Cal., where equipment has been devised and searching tests conducted. Progress in evolving equipment was slow, the machinery and methods being developed along original lines, and only recently were definite results available. The effects of quality of aggregates, grading materials for strength and imperviousness, quantity of mixing water, rock dust and improving water tightness, curing, amount of tamping, and comparison of strength of specimens tested dry and saturated were the angles of contact included in the experiments of the laboratory and yards of nearby factories.

The age-old method of testing the tensile strength of pipe was discarded by reasons of being cumbersome and costly, involving the disposal of huge volumes of waste water. Essentially, this antiquated method consists in the formation of a testing section composed of a number of joints of pipe of the desired diameter, bulkheading each end, the latter being secured by means of a connecting tie rod and then applying water under pressure to the interior until rupture ensued. Substituting therefore, F. W. Stanley and E. C. Fortier of the field laboratory of the Bureau of Public Roads, developed a plan of determining the strength of each joint separately without the use of bulkheads, the joint subjected to the test being influenced by no force other than the water pressure within its shell.

The newly-devised method of testing the tensile strength of the pipe is accomplished by use of a cylinder of galvanized sheet iron corresponding to the length of the pipe joint having grooves at each end, in each of which is inserted a small rubber tube resembling the inner tube of an automobile tire. The cylinder is placed inside the joint of pipe subject to testing and the rubber tubes are filled with water until they press tightly against the inner periphery of the pipe. Water is forthwith admitted into the small annular space between the cylinder and the inside of the pipe. Thereby watertight connections are insured with the same pressure in the tubes as exerted against the concrete pipe. The equipment is portable and can be readily conveyed from one concrete-pipe-manufacturing yard to another where stock pipe can be tested. Likewise the usual

*Left:* Canvas envelope in position, to protect men and work during bad weather. *Center:* Stack-building machine in position for the ninth fill on an 80-foot chimney. *Right:* Finished chimney, showing the flutings that add architectural charm

**Concrete chimneys of character, and how they are built**

## The Architecture of the Concrete Chimney

By G. Orb

IN line with the popular idea that coniform chimneys possess the most pleasing lines, a stack-building machine recently brought out not only adopts this style of architecture but it further ornaments the monolith with a series of vertical and integral ribs which extend the entire height of the structure, dying out in the base of the ornamental top. These ribs are half round in cross section and add strength as well as beauty to the chimney.

The machine used in this class of construction is really a steel cage, carrying the entire construction equipment, and the underlying principle of which is the steel center-mast. This center-mast, with a set of radiating steel tees, makes possible unusual accuracy in every line and absolute uniformity in the taper as the diameter decreases. The overlapping of the wall-forming shells, which are framed in small angles, takes care of this decrease in diameter as the height is increased.

At no time is there any scaffolding in use, either on the inside or the outisde of the chimney, as the workmen use the construction ladder which hangs from the machine. A rib-forming corrugation is stamped in each section of the outer forms; and these forms may be readily removed when it is desired to place reinforcing, thus giving easy access to the work at all times.

The working platforms are carried by the machine itself—the supports of these being elaborated into the steel cage. If the weather conditions are unfavorable, a canvas envelope may be let down over the entire cage and the work proceeds unhindered, with complete disregard for temperature and precipitation.

Due to the rigidity of the machine and the ruggedness of its manufacture it is possible to use the much desired quaky and efficient, though heavy, concrete mix—thus requiring a minimum of materials.

A recently built chimney 5 feet in diameter at the bottom, tapering to 4 feet at the top and 100 feet high, was completed in twenty-one days by four men. The ordinary rate of construction is about six feet per day. The accuracy of construction and ornamentation, as well as the very great reduction in the cost, which the new quipment makes possible, will no doubt do much toward popularizing this method of putting up the big stacks so necessary in modern industry.

**The equipment employed in testing of concrete pipe, and a test carried to the failing point**

# Hardening Steel in Gas Fired Furnaces

## Some Interesting Details of One of the Leading Modern Heat-Treating Processes

By W. A. Ehlers, M. E.

PRACTICALLY all alloy steel used in the manufacture of machine parts and for other purposes where static and dynamic strength is required must have some form of heat treatment in order that it may possess the necessary strength, withstand vibrations, resist impact, have tortional resistance and good wearing qualities when two parts are in moving contact with each other.

This is very well illustrated in the manufacture of an automobile. The gears which are subject to wear must have hardened surfaces or abrasive hardness if they are to run smoothly. The springs must be flexible but not break. The steering mechanism must be very tough and free from brittleness. The crankshaft must withstand the impact of the connecting rods. The front and rear axles must be made to withstand the vibration and shock from the irregularities of the road, and in addition the rear axle must have tortional resistance to transmit the power from the rear transmission to the rear wheels.

Thus it may be said that a steel to meet the above requirements must have a high limit of endurance for the normal stresses and at the same time be able to withstand the abnormal stresses. It is a matter of experience to determine which quality in the steel must be given prime consideration. It also must be remembered that the heat treating process may entirely change the properties of the steel in their relation to the above-mentioned qualities.

Hardness is one of the properties of steel which is probably more often required than any other. It is that property by which the steel resists penetration.

The process of hardening is similar to that of annealing, except that instead of slow cooling, the steel is quenched quickly which causes it to become hardened. There are, therefore, two important operations in this process to be considered—the rate and ultimate temperature of heating, and the method of cooling.

In the hardening operation the same precautions are to be observed as in annealing, viz.: heat slowly and uniformly; do not exceed but slightly the upper critical temperature of the steel being heated. When the steel has thus been brought to the proper temperature the same transition has taken place as in annealing process, that is, the constituents have been changed into the hard structure known as austentite. Upon being suddenly plunged into the quenching bath while at this temperature, the rate of cooling is so sudden that there is little if any further change in the structure of the steel and it then takes the form of austentite, or if allowed to cool slightly it may change back to martensite or troostite.

One of the greatest mistakes made in the hardening room is in attempting to harden steel pieces of any considerable size such as dies in an open coal forge. It must be admitted without argument that such pieces cannot be evenly heated in such fires. Uneven heating will necessarily produce uneven cooling, which in turn will cause uneven strains in the steel, and result in hardening cracks. Gas heated furnaces for heating such steels are far better suited for the work since the rate of heating can be easily controlled and the uniformity of the gas heated oven is all that could be desired. Not only can a very uniform temperature be maintained in all parts of the furnace but the temperature of gas-heated furnaces is subject to positive and automatic control, thus eliminating any tendency to overheating which is very important in heating steels when approaching the critical temperature for that particular alloy.

Heating steels for ordinary hardening can be accomplished in several ways. The most general practice is to use oven furnaces for such work. When this type of furnace is used for high speed steel, the work should be preheated to about 1,100°F. and then placed in an oven having a slightly reducing flame, and a temperature ranging from 1,800° to 2,400°F. according to the character of the tool and the composition of the steel. There are, however, some classes of work which can be better handled perhaps in a liquid bath consisting of molten lead or salts. Small pieces such as typewriter and adding machine parts, spiral springs, cutlery, and long, slender tools such as drills and reamers may be handled better in such bath. This method will not only give uniform heating but there is less chance of overheating and oxidation. Lead, however, is expensive and therefore cannot very well be used for large pieces. It offers many disadvantages such as sticking to the parts immersed, and unless the surface is well covered with charcoal it volatilizes very easily and these fumes are poisonous.

To prevent lead from sticking to the work, cover the tools with a paste made of whiting mixed with alcohol, or dip them in a strong solution of brine.

Heating in salt solutions is very practicable and offers some advantages over lead. Pure table salt may be used, or mixed with chloride of potassium in different proportions and thus almost any predetermined temperature may be obtained. The melting point of the mixture may thus be used as a guide to determine the proper heating temperature.

Barium chloride baths are sometimes used for hardening high speed cutting tools. Its use however has been very much limited on account of the fact that very few operators know enough about handling it to have pronounced success. It consists of a salt melting at about 1,625°F. and is usually heated in furnaces with crucibles. The upkeep cost of such crucibles at the present time make this method almost prohibitive. One of the great advantages in this method of heating lies in the fact that tools having cuting edges do not suffer from oxidation as in other methods of heating, because on removing the tool from the bath a thin film of the solution adheres to the metal and prevents contact with the air. Work which is to be heated in barium chloride should first be preheated to a temperature of at least 1,000°F. before placing in the bath. Frequently this type of furnace is operated at such a high temperature (over 2,200°F.) that pitting of the steel occurs. This may be avoided by carrying out the hardening process at a lower temperature.

The second operation of importance in hardening is the method of quenching. This not only applies to the kind of quenching bath but also to the way the part is handled in the bath.

Cold water, oil, and air offer the best means of cooling the steel. Air, however, can only be considered for such work where scaling is of no consequence or where the work can be ground after hardening.

Brine is used where extreme hardness is desired but unless unusual precaution is taken in having the work heated very uniformly this method is very likely to crack the steel.

Even plain cold water is very severe on the work and like brine may cause trouble on account of cracking. Yet for a great many classes of work this method is preferable. Steel ball bearings are an example wherein extreme hardness is desired and where water quenching is therefore preferable. A majority of the quenching is done in oil baths, particularly high carbon steels, and those used in places where the specimen may be subjected to considerable shock. Spring steel likewise should be quenched in oil. This method

## The Last Race for the Gordon Bennett Cup

**By John Jay Ide**

THE Sixth Gordon Bennett Aviation Cup race took place near Etampes, France, on Tuesday, September 28th. It was won by Sadi Lecointe on a French Nieuport biplane equipped with a 300-hp. Hispano-Suiza engine. As this was the third consecutive time that the cup had been won by a French pilot it now passes permanently into the possession of the Aero Club de France.

The contest was held over a 50-kilometer course extending from the aerodrome of Villesauvage to La Marmogne. Three rounds of this course had to be covered, making a total of 300 kilometers (186.45 miles). On the previous Saturday a race of 100 kilometers to determine the three French entries had been held. This had resulted in the elimination of Casale (Spad) and Barrault (Borel), leaving Sadi Lecointe and Kirsch (Nieuports) and de Romanet (Spad) qualified.

To represent the United States the contest committee of the Aero Club of America chose one of the two Curtiss machines brought over by Mr. Cox, the Verville biplane entered by the Army Air Service, and the Dayton-Wright monoplane. The pilots of the American entries were Rohlfs, Captain Schroeder and Rinehart, respectively.

England was to be represented by a Sopwith biplane (Hawker), the Nieuport "Goshawk" (Tait-Cox) and the Martinsyde "Semi-quaver" (Raynham).

The Curtiss was wrecked in landing on the rough aerodrome at Etampes Sunday evening after flying down from Villacoublay where it had been assembled. The pilot, Rohlfs, was rather badly injured but was able to leave the hospital to see the cup race. Of the English entries the Sopwith never appeared owing to the collapse of the Sopwith Co. a few days before the race, and the Nieuport arrived too late.

The actual starters, therefore, were:

*France*—Sadi Lecointe (Nieuport, 300-hp. Hispano-Suiza); Kirsch (Nieuport, 300-hp. Hispano-Suiza); de Romanet (Spad, 300-hp. Hispano-Suiza).

*America*—Captain Schroeder (Verville, 600-hp. Packard); Rinehart (Dayton-Wright, 250-hp. Hall-Scott).

*England*—Raynham (Martinsyde, 300 hp. Hispano-Suiza).

During the morning the course was covered by a fog which did not begin to clear off until noon. It was thought for a time that the race would have to be postponed until the following day but after several test flights had been made it was decided that it could commence.

The French team had been taken out on the field at about 11 o'clock and had their motors tested, etc. De Romanet's Spad appeared with a new fin and rudder put on overnight, the old ones having proved too small for proper lateral control. While on the field the standard wheels of the Spad were replaced by those of the racing variety having tires and wheels completely enclosed in fabric casings.

The American and British machines were wheeled out of their hangars at about one o'clock. The former joined the French group on the field but the Martinsyde for some reason occupied an exclusive position about 300 yards away.

In the middle of the preparations for the start Tait-Cox arrived in a British Nieuport "Goshawk," bursting a tire on landing.

The first man to start in the race was Kirsch, who crossed the line at 1.36.25. He was followed by de Romanet at 1.44.52. Sadi Lecointe started at 2.8.54 and Rinehart at 2.11.10.

Great difficulty was experienced in starting the engine of Captain Schroeder's Verville and as the rules state that the contestant must cross the line within half an hour of the starting time he has chosen some anxious moments were passed by the American contingent. Finally the Verville got away just within the time limit at 2.37.2. The British contender did not leave until all other competitors had either finished or abandoned the race, waiting until 4.34.36 for absolute calm and cooler atmosphere.

Kirsch, the first starter, made the best time over the hundred kilometers (62.15 miles) which he covered in 21 minutes 29 seconds. Toward the end of the second lap, his engine began to miss and he abandoned the race after completing 200 kilometers (124.3 miles) in 48 minutes 52 1/5 seconds.

De Romanet ran a fine race against heavy odds. Near the end of the second lap an oil pipe broke, covering the pilot with lubricant. He landed at the aerodrome, made a hasty repair and took the air again, completing the race in 1 hour 39 minutes 6 3/5 seconds. De Romanet's time for 100 kilometers was 22 minutes 52 seconds and for 200 kilometers 46 minutes 7 seconds.

Sadi Lecointe, the French favorite, gave all spectators the impression of consummate skill. After taking off he flew around until he succeeded in obtaining perfect carburetion. Following this he rose to about 3,000 feet to pick out the most direct line to the other end of the course. He then descended to about 40 feet from the ground, crossed the line and in a few seconds disappeared on the horizon without, apparently, having deviated a foot from the course he had set himself at the start.

Lecointe's piloting on the turns aroused great enthusiasm. His system was to bank the machine several hundred yards before the line. Just before reaching it he would kick the rudder hard over, centrifugal force carrying him beyond the line in a turn approximating the vertical, the machine cutting the line again within three seconds. In less than a hundred yards the Nieuport would be on an even keel again speeding toward La Marmogne. The finishing line was crossed at a bare ten feet above the ground, the 300 kilometers (186.45 miles) being covered in only 1 hour 6 minutes 17 1/5 seconds, thereby creating a new world's record. The old record (2 hours 51 minutes 53 4/5 seconds) had been held by Tabuteau ever since January 21, 1912. Lecointe's time for 100 kilometers was 21 minutes 36 3/5 seconds and for 200 kilometers 43 minutes 42 3/5 seconds. Lecointe's time for 200 kilometers is also a new record, the old one having been made by Prévost in the last Gordon Bennett Cup race September 29, 1913 (59 minutes 45 3/5 seconds), also witnessed by the writer.

Meanwhile the two American entries had made very disappointing exhibitions, the Dayton-Wright having landed at the expiration of twelve minutes. It appeared that the top threads of the worm shaft controlling the hinged leading edge of the left wing (one of the novel features of this machine) had stripped causing the edge to flap when in the high speed position. This, of course, rendered the machine uncontrollable.

Captain Schroeder was forced to return when almost at the other end of the course on his first round due to motor preignition caused by insufficient radiator surface for the very warm day. The Verville gave an impression of tremendous speed and it is most regrettable that the enterprise of the Army Air Service in designing and in sending over this remarkable machine did not have a better reward. The design work has by no means been lost, however, as with a few alterations the Verville can be turned into a pursuit machine second to none.

Raynham, who, as noted above, did not start until after half-past four returned to the aerodrome before he had completed 100 kilometers owing curiously enough to a similar mishap to that of the de Romanet—breakage of the oil feed. Raynham's Martinsyde is the identical machine which won the Aerial Derby around London last July. It is a smaller edition of the Martinsyde Scout—the fastest British single seater produced during the war.

The Spad entry was a standard model 20 with reduced wing gap and with a cover, carrying a fairing for the pilot's head, over the observer's cockpit. The performance of de Romanet therefore greatly redounds to the credit of M. Herbemont, the designer of the machine.

The Nieuport machines are a development of the model 29C1, which would have been adopted as the standard pursuit airplane by the French Army had the war continued. The Gordon Bennett models however are much smaller than the 29C1 type, having only one pair of struts on each side of the fuselage.

## Accumulated Data on the Distribution of Stars in Space

By Professor Henry Norris Russell, Ph. D.

A PAPER of more than usual interest has just been published by the Dutch astronomer, Kapteyn. For many years this distinguished student of the stars has devoted his unflagging energy and keen insight to the collection of information about the brightness, motions, and distances of the stars—all with one great purpose consistently in view: the determination of the structure of the stellar universe. How thickly are the stars scattered in space? What proportion of them is bright, and what fraction faint? Does the starry region extend indefinitely far in all directions, or is it limited and surrounded by relatively, if not quite, empty space? If so, what is the shape and size of the star-filled region? Is it sharply bounded, or does it thin out gradually at the edges? These, and questions like them, have been the problems to which Kapteyn has devoted his researches; and at last, after years of labor, aided by the coöperation of observers at many places, and of skilled assistants, he and his associate, Dr. Van Rhij'n have found themselves ready to give out preliminary answers.

Space would fail us here to tell the tale of how these answers were obtained. Suffice it to say that the methods were mainly statistical—determining the number of stars in the sky which appear to us of each stellar magnitude; then finding out what percentage of the stars of each magnitude had proper motions between given limits; proceeding from this to estimate what fractions of the whole number lay at different distances from us—and so on—with a multitude of minor but still important and difficult problems coming up, now and again, which had to be solved before the main work could be completed.

The results, however, are easily enough understood. In presenting them here, we will translate the technical but unfamiliar terms "absolute magnitude" and "parsecs" into the more generally familiar ones of brightness compared with the sun, and distances in light-years.

### Our Sidereal Neighborhood

Within a hundred light-years of our sun, the stars appear to be scattered with fair uniformity in space. The number which lie within this distance, according to Kapteyn's new calculation, is 6,200. If we limit ourselves to half the distance, we should expect to find, not half as many stars, but one-eighth as many, since the region in space within which we are looking for them is a sphere with only half the diameter of the one we had at first, and hence contains only one-eighth as many cubic light-years. Only one in a thousand of the 6,200 stars should be within ten light-years of us—that is, six in all. Four stars are actually known to be nearer than this—Alpha Centauri, Sirius, Barnard's "runaway" star, and the seventh magnitude star known as Lalande 21,185; and two or three others are so near the limit that we can hardly say whether they are inside or outside it. Then we must not forget the sun itself, which is a star essentially similar to the others; and so we have in all six or seven stars within this region of space, in perfect agreement with Kapteyn's calculations—though in the case of so very small a sample of space, so close an agreement is probably a matter of good luck.

But even among these nearest neighbors of ours we find enormous differences of real brightness. Sirius is more than twenty times as bright as the sun; Barnard's star gives out only 1/2500 of the sun's light. How is it among the stars in the wder field which Kapteyn has made his own?

His calculations show that a surprisingly definite answer may now be given. The great majority of stars in any given region of space are fainter than the sun, and really bright stars are rare. For example, out of the 6,200 stars nearer than 100 light-years, 790, or only one-eighth of the whole number, may be expected to exceed the sun in brightness. About 100 of these will be ten times as bright as the sun, or more; and only five or six will exceed 100 times the sun's brightness. Only one star in 50,000, on the average, is 1,000 times as bright as the sun, so that we would not expect to find such a star as near as 100 light-years. We can be sure that there is actually none, for at this distance a star 1,000 times brighter than the sun would look to us brighter than Vega. There are only three stars in the sky brighter than this. Two of them, Sirius and Alpha Centauri, are very near us and of moderate real brightness; the third, Canopus, is certainly more than 1,000 times as bright as the sun and certainly more than 100 light-years away.

But we have said nothing yet about the stars fainter than the sun, though these constitute the majority of the whole—5,410 out of the 6,200 stars aforesaid. About 3,400 of these will give out less than one-tenth as much light as the sun, leaving some 2,000 in the intermediate region of brightness; and of the 3,400, 2,200 will be found to possess a luminosity between ten per cent and one per cent of the sun's.

Among the remaining 1,200 still fainter stars, objects of very small luminosity appear to become rare. Some 200 of them are less than 1/1000 as bright as the sun. Our information about these very faint stars is still scanty; but according to Dr. Kapteyn's present data, only a dozen will be less than a ten-thousandth of the sun's brightness.

NIGHT SKY: NOVEMBER AND DECEMBER

### Some Apparent Paradoxes

According to this census of the stars, we may therefore regard our sun as a pretty bright object, surpassing seven out of eight of his fellows. But how are we to reconcile this with the fact—demonstrated securely by direct measures of parallax—that the majority of the brighter stars in the sky are much more luminous than the sun? This apparent paradox arises because the stars visible to the naked eye—or, for that matter, above any assigned limit of *apparent* brightness—are not a fair sample of the whole, but are hand-picked (or it would be better to say *eye-picked*) to an amazing degree.

Let us compare, for example, the stars which are between 10 and 100 times brighter than the sun with those which are between 10 and 100 per cent of the sun's brightness. We found above that there were 2,000 of the latter class within 100 light-years of us, as against a little less than 100 of the former—a disparity of twenty to one. The stars of the brighter group, even if at the limiting distance, would *all* be easily visible to the naked eye as stars of the fifth magnitude or brighter. But those of the other group, if at a distance of 100 light-years, would appear as stars ranging from the seventh to the tenth magnitude, and so would not get into our list of naked-eye stars at all. Only a few of them, which are less than twenty light-years away (or ten light-years, for the faintest members of the group) will be easily visible to the naked eye; and these will be but a beggarly fraction of the whole number.

Speaking more generally, the stars of the first group, on the average, are 100 times as bright as those of the second. We can therefore see them at ten times the distance, and we will be hunting for them throughout a region of space a thousand times greater than that to which our search for stars of the other group is limited.

For every star of the fainter sort which gets into our list of naked-eye stars, there will therefore be fifty stars of the brighter kind—and a thousand of the fainter sort which, though no farther away from us than the brighter ones which we have listed, are invisible to the naked eye.

This thousand-to-one preference, converting a real minority of five per cent into an apparent majority of 98 per cent, is not at all an exaggerated example of the effects of observational selection. In some cases, as between stars like Vega and Arcturus and objects like Barnard's star, the preference would be a million to one—so that it is not surprising that only one isolated star as faint, in reality, as Barnard's has been discovered among the half-million or so stars brighter than the tenth magnitude.

Closely allied with this effect is another curious and half-paradoxical fact. The total amount of light given out by the 6,200 stars which we may, by stretching our definition of neighborhood somewhat, call our neighbors in space, comes out 6,500 times the sun's light; so that the average amount of light given by one star is very nearly equal to that of the sun. But a simple calculation shows that 87 per cent of the stars, which are fainter than the sun, give out only 12 per cent of the total light, the remaining 13 per cent giving out 88 per cent of the total. The stars which are more than 15 times as bright as the sun, though numbering only one per cent of the whole, give out half of all the light. Such considerations illustrate what extraordinary differences will appear in our point of view and in the results which we obtain, according as we count the stars as they appear in the sky, or measure them by their light-giving power. The novice will find many pitfalls in such statistical studies, and even the well-equipped student, if not explicitly on his guard, may be caught. It need hardly be added that such effects have been very carefully allowed for in Kapteyn's monumental work.

### The Heavens

Turning to our star-gazing, we find Orion high in the southeast, with Sirius below, Aldebaran and the Pleiades above, and Procyon on the left. Perseus and Auriga are overhead, Gemini high in the east, and Leo rising. Ursa Major is low in the northeast, and Ursa Minor and Draco in the north. Cassiopeia is high in the northwest, and Cygnus is setting far below. Pegasus is well up in the west, with Andromeda above. Cetus and Eridanus occupy the great dull region in the southwest.

### The Planets

Mercury is an evening star before the 16th, and a morning star afterwards, but is visible only at the very beginning and end of the month. Venus is an evening star, but is still very far south, and sets before 8 P. M. Mars is an evening star, too, and sets about an hour and a half after Venus.

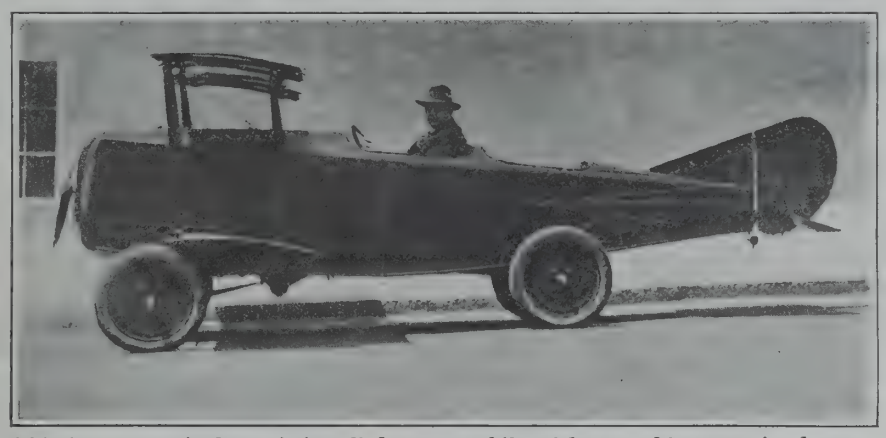
(*Continued on page 460*)

## An Airplane Not Built to Fly

THE accompanying illustration shows an airplane built on a light car chassis by a San Francisco automobile company. The machine is used as a stunt; that is to say it is an advertising car and not a flier.

The propeller of this novel airplane that never leaves the ground may be operated from the engine of the car if desired. The machine is built exactly on the lines of an airplane, being provided with rudder and elevators, the rudder being connected with the steering wheel by means of cables in such a manner that the rudder turns to the right and left as the steering gear is manipulated, thus acting as a direction indicator to the motorists in the rear.

The elevators are operated by the controlling lever as in an ordinary plane, and when the car is brought to a standstill the elevators are lowered in the same position as on a plane when descending. The car is equipped with airplane tires with special tread in the rear to conform with the narrowness of the body toward the rear. The car carries port and starboard lights controlled by a switch. The car is a two-seater.



**This is not an airplane; it is a light automobile with something new in the way of a freak body**

## A Ferryboat Built on Motor-Boat Lines

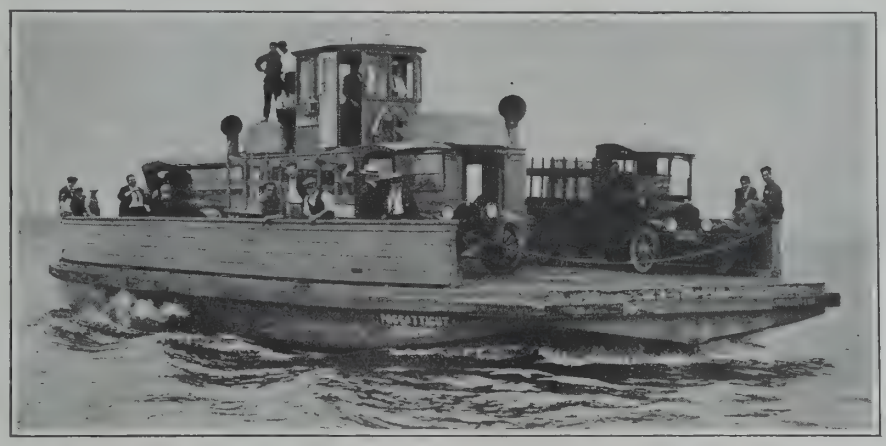
BECAUSE of the limited traffic to be handled, a gasoline engine is being used in connection with the ferryboat "Poggatticut," which operates between Greenport and Shelter Island Heights, at the eastern end of Long Island, N. Y. This boat makes round trips twice an hour, accommodating eight automobiles on uncovered runways alongside the central passenger cabin. Licensed for one hundred passengers, she is operated by a gasoline engine and a two-man crew consisting of the pilot-engineer and a deck hand. Truly, this is economical operation and quite in keeping with the limited traffic.

The "Poggatticut" is 64 feet long, 28 feet overall beam, 4 feet 11 inches draft loaded, with a gross tonnage of 72.6 and a net tonnage of 57. This ship is constructed with straight floors from keel to bilge corners, with the fore and aft treatment carefully worked out. Indeed, she makes scarcely a ripple when traveling at eight miles per hour.

The operation of the ferryboat is entirely from the pilot house, which is equipped with engine and clutch controls. This house is directly connected with the engine room by a vertical ladder shaft with a sliding door opening to main deck runway, and has a door on each diagonal side to the boat deck where two wooden ponts, equipped as life boats and totaling the required life-boat capacity, are checked bottom up.

The power plant is extremely novel, comprising an automatic 50-horse-power double flywheel engine, with a one-way clutch at each end connecting to the continuous-line shafting with a propeller at each end. The forward propeller runs idle while the boat is being driven forward, but comes into play when a reverse action is wanted. The rudders are fitted with locking pins and protected by an armored ram for operation in ice of reasonable thickness.

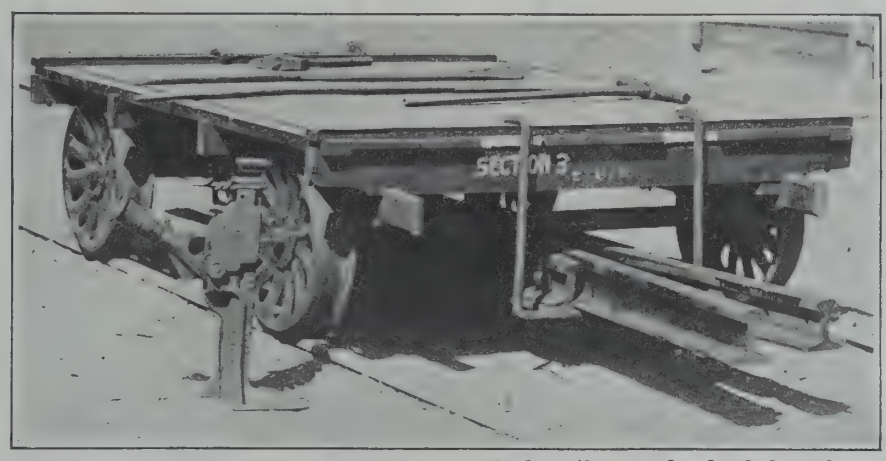
The remarkably steady running and maneuvering qualities of the "Poggatticut" are its strongest talking points, since the heavy tides encountered on her route call for an extremely manageable craft.



**The "Poggatticut"—a two-man ferryboat which carries 100 passengers and eight automobiles**

## Loading Rails With a Jack

THOSE who have to do with the handling of lumber have, in many instances, discovered that these shapes, long and narrow to the last degree are frequently best manipulated with the aid of an underslung carriage of some sort; and the SCIENTIFIC AMERICAN has on several occasions described and pictured such appliances. A new member of the family now comes to our attention, the invention of Mr. Arthur Vinet of Winnipeg. This time the intent is to facilitate the handling, not of lumber, but of another shape equally long and if anything even narrower—railroad rails, frogs, etc. It will be noted in the picture, which really tells the story of Mr. Vinet's invention, that the hooks forming his underslung carriage are not a permanent feature of the flat car on which they are installed, but that they can be removed from and added to the car almost as easily as the rails can be loaded on and unloaded from the hooks themselves. The procedure for loading, after placing the rail or frog to be loaded in the center of the track, is to run the car over it, put a track-wrench through the bolt holes at either end of the piece to be loaded, jack up the ends of the frog until it reaches the axles of the car, and then place the hooks. The idea has proven so good in practice that Mr. Vinet's invention has been installed in the Canadian Pacific terminals throughout Canada.



**The temporary underslung carriage on which rails can be loaded with no other tool than a jack**

## Where Age Improves Germination

THE seed of some garden vegetables is never saved by amateurs for the reason that the plant is a biennial, and doesn't make seed until the second year. Cucumber seed is seldom saved probably for another important reason and that is the germination factor. Cucumber seed only a year old is characteristically poor seed. Germination improves with age. Seed houses never plan to sell cucumber seed which is not at least two years old. Seedsmen, as the professional gardener is perfectly well aware, know that cucumber seed is at its best at three years; that it is excellent at five years. Not only does aged cucumber seed have higher germination, but it produces much stronger plants. Plant cucumber seed fifteen or even twenty years old, and a great deal of it often will come up.

As in the case of cantaloupes, the cucumber seed business of the United States is largely in the hands of expert growers who control large acreages. Some of the big growers have as much as 200,000 lbs. in storage at one time. The warehouse is mouse-proof and fire-proof, and so that they may guarantee seed free from disease the cucumber specialists disinfect it.

Here, as in many other fields of agriculture, constant experimental work is the price of progress. Corrosive sublimate is the agent used in treating seed. In doing this for a long time many growers dissolved the poison in cold water until an expert showed them that either hot water or wood alcohol must be used to make the solution. Corrosive sublimate "dissolved" in cold water simply sinks to the bottom.

Another little point that had to be worked out was the strength of the solution. The proper percentages of corrosive sublimate, it has been determined, is 1-1,000. A proportion of 1-200 will kill all the seed, 1-400 most of it, 1-600 some, 1-800 a little.

Rinsing the seed is an operation which has led to ingenuity. Formerly the practice was to rinse it for a long time in running water; most growers do now, in fact. One of the largest operators introduced a better method. He uses a little lime water, and the work of rinsing is radically reduced.

## Putting Paint to the Acid Test

THE untiring Bureau of Standards has recently undertaken to test paints on a scientific basis; or, in other words, to take the guess work out of paints. For paints are used as much or even more for preservative purposes than for decorative purposes, and something definite should be known in advance regarding the wearing qualities of any paint.

A series of racks has been erected on the roof of the Chemistry Building of the Bureau of Standards, as shown in the accompanying view. On these racks are placed slabs or panels of wood and metal, coated with the paints and varnishes to be tested. The slabs or panels are exposed at an angle of 45 degrees to the vertical facing south so as to get the most severe exposure. In this manner the paints and varnishes are subjected to the most extreme conditions that would be encountered in normal use, and the experts of the Bureau are enabled to gage with considerable accuracy the wearing qualities of various paints and varnishes. Not only does the Bureau test the samples submitted by manufacturers, but the very elaborate paint shop of the Bureau is carrying on important research work in the way of guiding all efforts toward better paints and varnishes.

A handy tool for the repair of unwieldy truck tires

## Electric Buffer for Truck Tires

A HANDY tool for shop or garage use in repairing truck tires is the equipment shown here. The equipment consists of bench stand with flat pulley, five feet of shafting, spindle and scratch brush. The equipment can be driven from the line shaft or from a motor as shown. It is said to do efficient and economical work.

## Trunk with an Ironing Board

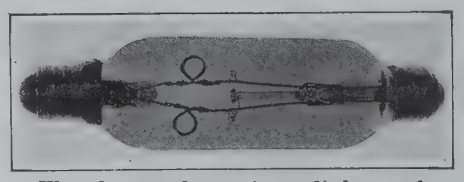
WARDROBE trunks were thought to be the last word in traveling equipment when they were first introduced a few years ago. The various compartments for wearing apparel were then as convenient as the makers knew how to make them. But a 1920 model wardrobe trunk made by a Chicago manufacturer would make the old models shiver with shame. The newer trunks have made use of the pressure board, used to keep the wrinkles from garments hung upon the hangers, as an ironing board combination. This board, used formerly for but one purpose, now serves two. Upon one side it is padded and has the outer end rounded so that the owner can easily press the shoulders of shirts or blouses. The firm foundation is possible because of the upright support which clamps to the outer end.

Various other improvements are also found in the trunk, such as collapsible hat boxes, shoe compartments, electric iron space, umbrella and cane rack, not to mention an improvement in locking. By a single motion of the hand on the top locking device, two other locks located below are secured at the same time. This eliminates stooping over to fasten the lower locks.

A wardrobe trunk equipped with an ironing board

## Light and Power from a Single Bulb

A TWO-BASE incandescent globe has been designed by E. O. Schmeitzer, an electrical engineer of Chicago, Ill. With this globe it is now possible to have light and power from the same socket without connecting a double base socket. The new globe is simply connected in the old way and any heating device that might be wanted for use such as a cold water warmer, electric iron, etc., is connected to the end opposite. The design of the globe has been changed somewhat to a cylindrical shape with a tipless end. The exhaustion of the bulb has been carried out by means of a sealed-off tube concealed within one of the bases. The lead wires are given a quarter twist in passing between the two ends of the lamp to provide clearance for the filament anchors. Old designs of electrical devices used in the home can now be



The lamp that gives light and power at the same time, auxiliary apparatus being connected at the "other end"

quickly and cheaply changed to provide more harmonious lighting effects. What is known as a "pendant" fixture can be converted into a semi-indirect fixture by the use of the new lamp.—By *K. H. Hamilton.*

## New Sources of Power Alcohol

THE opinion gathers force that there are ample sources of the raw materials of power alcohol available in regions where the difficulties in connection with the transport of plant and machinery required and of the product to the consuming centers are not so great as in some of the areas which have been marked out as ideal raw material producers, according to the *Times Trade Supplement.*

It is reported that in the Pacific Islands alone, maize, cassava and sugar cane could be grown and utilized to an extent which should produce 50,000,000 gallons a year, and it is suggested that the world demands could be filled by the raw material available within certain Empire areas. Estimates of the cost of obtaining industrial alcohol from the crops named indicate that 6d. per gallon is a figure which could be realized, and the process of distillation should be associated with the recovery of valuable by-products.

## Floating Fair from the Netherlands

A COMPANY has been organized at The Hague for the purpose of sending a "floating fair" as it is called, but practically a ship loaded with sample products and commercial agents to sell them, to various parts of the world, particularly the United States. The concern is organized somewhat on a coöperative basis and proposes to send the Messageries Maritimes vessel, the "Macedonia," of 6,100 tons burden to the United States and Central and South America for the purpose of introducing Netherlands products and enabling Netherlands commercial houses to establish import and export connections in the countries visited.

The plan is for each of the Netherlands firms going into the scheme to advance the sum of 2,800 guilders or, at present exchange, the equivalent of $861 American currency, for each cubic meter of space occupied aboard the vessel by an exhibitor and 200 guilders or about $61 gold for each port visited. The ship will be divided into show rooms and each exhibitor will instal aboard the vessel in the space he engages such a display of his goods as he cares to make and will furnish the company with advertising matter, price lists, and other information. The company will furnish an organization of commercial men on the ship which will act as sales agents and will endeavor to arrange satisfactory permanent connections for the exhibitors in the ports visited. For sales actually made the company will charge a single commission of 10 per cent, taking no commission on the business which follows from connections thus made. It proposes to carry on a comprehensive advertising campaign in the countries to be visited so as to secure the maximum result from the visit.

## New Lathe Dog with Safety Feature

A LATHE dog being manufactured by an Ohio firm is fitted with a recess into which the set screw head fits and the danger of breaking projecting set screws is eliminated. Extra metal used in forming the recess serves to balance the dog. The screw of the dog is set with a socket wrench.—By *Allen P. Child.*

Setting the screw of the safety lathe dog with a socket wrench

## Restoration of the Belgian Railroads

TRADE COMMISSIONER SAMUEL H. CROSS reports from Brussels, Belgium, under date of August 25, that the severely damaged railroad section from Mons to Ghlin has been completely rebuilt, and the bridge over the Lys just outside the St. Pierre station at Ghent has lately been opened for double-track use. The Alost-Opwijk-Londerzeel and Dixmude-Nieuport lines are nearly ready for operation, while the Courtrai-Menin line is open as far as Warneton. Interlocking block systems have been installed between Brussels and Antwerp and between Brussels and Ostend. A similar system is in process of installation on the Namur-Sterpenich route. Purchases of equipment are being made for the restoration of the electric switch systems in the larger stations. The central shops are repairing 12 locomotives per week, as against 19 in 1914, while the section shops have reached 50 per cent of their pre-war efficiency.

To protect the cotton-picker's fingers

## Finger Guard for Cotton Picking

ONE of the latest inventions for use in the cotton fields is a very simple cotton picker, consisting of a piece of flexible metal that is adjustable to fit the finger. It fits securely over the first joint of the finger, one to each finger. On the inside it has five small cleats to give tenacity. Experienced pickers declare that with a set of these pickers they increase their capacity from twenty to fifty per cent. The inventor is A. A. Ross of Oklahoma City, a practical cotton picker himself. With the labor shortage this picker is bound to prove popular throughout the cotton States. In addition to increasing the capacity of the worker, it also prevents pricking of fingers on cotton burs, a frequent and trying accompaniment of cotton-picking under the usual procedure.

## Throwing a Switch with the Foot

THE new San Diego and Arizona Railway has installed some foot-operated switches that make the life of the brakeman much easier and at the same time prevent a switch from throwing itself in the jar of a long freight train's passing over the rail intersection. When the arm operating the switch is thrown, it falls under a spring catch, from which it cannot emerge until the catch is opened by the foot lever seen in the picture. It is thus additionally safe and at the same time the brakeman finds it much easier and speedier than when he must put a pin in place after throwing the switch to hold the switch from jumping open.—By *Frank B. Howe.*

The foot-operated switch that can't be jarred open

# FAIRBANKS-MORSE

## Pioneers in the Ball Bearing Motor

FAIRBANKS-MORSE was first in this country to furnish a complete line of standard alternating current motors fitted with *ball bearings*. Needless to say, these machines were Fairbanks-Morse quality throughout.

This pioneer work was done many years ago.

Today, fully half the output of our electrical manufacturing plant is devoted to the production of ball bearing motors and generators.

Power users know the advantage of this type of motor for drives where practical operation demands the reduction of friction losses and the elimination of constant oiling. We accomplish this by means of grease-packed ball bearings which require but little attention.

This pioneer work and present day service to industry are the physical expressions of the standard reflected in the Fairbanks-Morse Quality Seal which images the goal of all this company's activities.

Our products include Fairbanks Scales—oil engines—pumps—electric motors and generators—railway appliances and coaling stations—farm power machinery, such as "Z" engines, lighting plants, water systems.

# Beauty and Utility

THE *practical* advantages of steel sash —its greater strength, longer life, and easier operation—are familiar facts.

But Lupton Pivoted Factory Sash lends itself equally to *beauty of design*.

Notice in the view below of the Crown Overall Manufacturing Co.'s building how the broad window openings—scarcely broken by the thin lines of the sash and mullions—emphasize the vivid white pilasters. Notice the balanced effect of the upper and lower ventilators in each window opening, and the harmony of proportion between the sash in the walls and in the corner towers.

Yet these upper and lower ventilators are not meant merely for looks; their real purpose is to give a balanced in-and-out air movement when there is no wind.

In a wide building like this, where many workers are likely to be crowded together, upper and lower ventilating openings are as essential to health as high ceilings and large glass areas are to easy vision.

We have published a 48-page booklet entitled "Air, Light and Efficiency," showing numerous sash applications to general manufacturing buildings. Some of them are very unusual. A copy will be sent free on your request.

# Recently Patented Inventions

*Brief Descriptions of Recently Patented Mechanical and Electrical Devices, Tools, Farming Implements, Etc.*

## Pertaining to Apparel

DRESS SHIELD.—HELEN WEEKS, 216 W. 140th St., New York, N. Y. The object of the invention is to provide means whereby a dress shield may be quickly, conveniently and securely attached to the dress without resorting to sewing or to the use of safety pins. Another object is to permit of readily attaching or detaching the shield without its being visible through the garment or without requiring alterations thereof.

## Of General Interest

OPENER FOR GLASS TOPPED JARS.—D. C. RELYEA, Coscob, Conn. This invention relates to kitchen utensils and has particular reference to manually-operated means for opening glass-topped fruit jars, which are usually held sealed by external atmospheric pressure. Among the objects is to provide an implement which will serve two conditions, first the admission of air into the container for relieving the external pressure, and secondly a device which is least likely to cause the cracking, chipping or breaking of either the glass top or the rim.

WINDOW ATTACHMENT.—J. E. GALBRAITH, 20 W. 14th St., Whitestone, L. I., N. Y. This invention relates to an attachment more especially designed to cover the opening between the top rail of the lower sash and the upper sash to prevent insects, dust, snow, etc., from entering the room by way of the opening. Among the objects is to render the attachment serviceable in case the lower sash is raised to insert a screen in the lower portion of the window casing. The device may be adjusted to windows of different widths.

GATE CLOSER AND SUPPORTER.—R. P. BELLICAN, Natchez, Miss. An object of the invention is to construct a device which will act as a supporter and closer for closures, and more particularly gates, by means of which the gate will always be properly closed, the closer also acting as a supporter for the gate as well as a hinge, thus tending to control the life of the closure and to eliminate adjustments and repairs to a minimum.

SOAP CONTAINER.—E. O'CONNOR, 166 Market St., Newark, N. J. This invention relates particularly to soap containers adapted to form a part of a douche or internal bath device, which compels the water to pass through the soap to render the water soapy and supply such soapy water in such quantity as may be desired.

ALLOY.—F. MILLIKEN, 55 John St., New York, N. Y. The object of the invention is to provide an alloy characterized by having a high acid-resisting quality, and increased density, an exceedingly close and fine grain, great tensile strength, increased elasticity, and electrical resistance. The alloy is formed of copper 50-60 per cent, nickel 26-34 per cent, iron 4-8 per cent, zinc, 7-11 per cent, and a deoxidizing or purifying agent, 25 to 5 per cent.

BED.—R. F. HELLWEG, 3660 Douglas St., El Paso, Texas. This invention relates to improvement in beds, an object being to provide coupling means between the side rails of the bed and the head of the bed which will permit the rails to be located either in position to support a spring or to support slats and to facilitate this double function, the side rails are of the ordinary angle iron form.

CHECK BOOK ATTACHMENT.—W. E. ABBOTT, Bend, Ore. An object of the invention is to provide a folding check book with a check clamp slidably engaging the checks and movable to a position across the field of the check so as to hold the checks smoothly while drawing the same, and which can also be moved into alinement with the division line between the check and stub, and operate as a straight edge against which the check can be torn.

SALT AND PEPPER BOX.—W. R. ELLIOT, Fairfield, Conn. This invention relates to salt and pepper boxes, having for its object a construction wherein separate salt and pepper receptacles may be supported by a single holder and controlled by a single cover so that only one box will discharge at a time. The two boxes are substantially duplicates with coacting means for holding a single movable cover in place adapted to stop the flow from either box.

GUN SIGHT.—E. E. GREGORY, Lewisport, Ky. The invention has for its object to provide a sight adapted for any form of gun, and so arranged that by using the sight with both eyes open the range will be automatically found. Two images of sight are formed when the marksman looking along the top of the gun barrel focuses his eyes on the target. These images appear transparent and in overlapping form an opaque central pyramidal image, the apex of which determines the point which should rest upon the target when the trigger is pulled.

BELL.—A. ROY, Hill City, So. Dak. The object of the invention is to provide a bell adapted to be attached to keys, as for instance, the keys of hotel rooms, for indicating with an audible alarm when the key is tampered with, by attempting to turn it from the outside, and which will also sound while the key is in the pocket through the movement of the carrier, thus preventing its loss.

BASKET.—G. L. O'DELL, 323 W. May St., Belding, Mich. The invention relates more particularly to an unwoven and unbraided, splint basket, although in all its phases it is not limited to baskets of that particular character. The general object is to provide a basket to be produced cheaper than braided baskets, and one which will give a better service.

DRIER TRAY.—C. E. JOHNSON, Boundbrook, N. J. The invention relates more particularly to trays used for the quick drying of dyes, paints, colors, chemicals, etc. An object is to provide a tray made of one sheet of metal bent into a shape such that a maximum drying surface will be exposed to the material to be dried and provide a plurality of passages which allow a free circulation of heated air.

DRINKING CUP HOLDER FOR WATER BOTTLES.—C. ROSENTHAL, 19 E. 9th St., New York, N. Y. The invention relates particularly to a device adapted to clamp upon the inverted upper end of a water bottle when the latter is in position in a water cooler, an object being to provide a device which will effectually support a carton or box containing a column of drinking cups in convenient position for use.

GROUND ANCHOR.—I. SOLBERG, 125 W. Stout St., Rice Lake, Wis. An object of the invention is to provide an anchor which will take a firm hold in the ground and which may be utilized for drawing an automobile out of a dangerous position, and which, of course, may be utilized for any other purpose wherever a rigid support is desired. A further object is to provide a ground anchor, which, when not desired for use, can be assembled and occupy but relatively small space.

WICKER PANEL.—W. H. STOCKER, 721 Lombard St., Philadelphia, Pa. The invention relates to panels of ratan, reed, willow or like material, and is adapted to be variously employed in the construction of furniture such as tables or chairs, or in building up walls or portions of walls. The general object is to provide a panel embodying frame elements and woven areas which will be strong and durable and will possess esthetic attributes to a high degree.

DRIP CATCHER FOR REFRIGERATORS.—A. B. BATES, c/o Genl. Deliv., Balboa Heights, Panama Canal Zone. The invention relates particularly to drip catchers for refrigerators, the object being the provision of a porous material arranged for catching the drip, which will obviate the removing and emptying of pans now commonly used for the purpose, the construction of the catcher effecting an evaporation of the waste water and in this way avoids the necessity of its removal.

We wish to call attention to the fact that we are in a position to render competent services in every branch of patent or trade-mark work. Our staff is composed of mechanical, electrical and chemical experts, thoroughly trained to prepare and prosecute all patent applications, irrespective of the complex nature of the subject-matter involved, or of the specialized, technical or scientific knowledge required therefor.

We also have associates throughout the world, who assist in the prosecution of patent and trade-mark applications filed in all countries foreign to the United States.

## The Problems of Electrification

*(Continued from page 444)*

ative costs show great economies. Another electrified western line is handling trains of 4,600 tons at a speed 20 per cent higher than was possible with steam traction and a limiting load of 3,500 tons.

Here in the East, down in a mountainous part of West Virginia where there is an extensive movement of coal from local mines, a railway formerly operated entirely by steam, now handles double the capacity on a certain section with 12 electric locomotives where it used to employ 33 great Mallet engines. The grades are extremely heavy, and yet, on the stiffest of these, trains of 3,500 tons are dealt with without trouble, and are moved about 100 per cent faster than when steam locomotives did the work. In fact, in numerous instances throughout the country, it is no uncommon thing to maintain electrified freight speeds of 15 miles or more an hour where formerly steam traction was limited to 6 and 8 miles. Thus we see how entirely feasible it is not only to reduce the bottle-necking condition but, at the same time to increase the loads which can be hauled by a single engine.

As is pretty generally known, several different systems of railroad electrification have been developed, each with its own particular claims to consideration. For the most part the lines so operated are not interrelated, and each typifies a more or less distinct step forward in the art; and as may be imagined each has its advocates. At present three lines focusing in the City of New York are using direct current of 600 volts, distributed by third rail. In effect this is an expansion of trolley practice to the main-line field—the third rail providing a conductor of sufficient volume to handle the heavy low-voltage current. Aside from complicating yard lay-outs and inviting numerous troubles, this arrangement is not suitable for long distances.

For trunk-line work, where the runs are of considerable length, we have naturally had recourse to trolley wires and high-voltage current in the distributive systems, and we have resorted to both direct current as well as single-phase alternating current on the roads concerned. The direct-current service has successively jumped from 1,500 volts to 2,400 volts, and then to 3,000 volts on the greatest electrified stretch in the country. But in order to obtain efficient primary distribution of energy from the power stations, alternating current of 100,000 volts is depended upon. This feeds to seven or more sub-stations along the route, where the alternating current is transformed to direct current of 3,000 volts by means of motor-generator sets installed at these points. As may be imagined, these sub-stations are necessarily complicated and extensive in their equipment.

Single-phase alternating current systems are in service in connection with a number of important roads in the East, where they are handling the varying demands of express and local passenger traffic and dealing efficiently with fast and slow freight on both fairly level and mountainous runs. Instead of motor-generator sets, as in the case of direct-current sub-stations, the transforming work is done by static transformers with no moving parts.

Similarly, where the overhead wires carry a much higher voltage than is needed for the operative motors of the electric locomotive or the multiple-unit train, small static transformers on either the locomotive or the cars meet every requirement. Structurally, they are of extreme simplicity, and besides are automatic in their functioning. High-voltage alternating current can be distributed farther, more efficiently, and by smaller conductors than is practicable in the case of direct current.

For multiple-unit operation, which must inevitably be counted upon to handle local passenger traffic in and out of populous centers, alternating current is preëminent-

# *Refinite Soft Water will lower your Operating Costs*

IF HARD water is going into the boilers of your power plant, into the dyehouse of your textile mill, into the washroom of your laundry or the laundry department of your hotel, hospital or other similar institution, you are carrying an unnecessary and easily avoidable operating expense.

Refinite Water Softeners have proven this fact for users in all parts of the country.

By their saving in fuel, in supplies, in equipment renewal, in time and in labor they have quickly written their costs from the books—and then kept right on adding to the profits.

**REFINITE**
IDEAL OF THE CHEMISTS
TRADE MARK
**Nature's Water Softener**
Copyright 1920—The Refinite Company

The Refinite Water Softener attaches to the cold water supply line. Occupies little space—requires no expert supervision, practically no attention—built in sizes to suit all needs—reasonable in price.

Refinite softened water is ideal for beauty parlor, barber shop and for home uses. Fresh, clean, velvety soft, it is soothing to the skin, beneficial to the complexion, delightful for the bath and shampoo.

**LIME-SODA WATER SOFTENERS—FILTERS**

We build also the Refinite Rapid Pressure Filter and the Booth Lime-Soda Water Softener. The latter is designed especially for railroads, municipalities and the larger steam power and central heating plants.

*Let us give you particulars about a Water Softener for your use. No obligation. Address our nearest office.*

**CHICAGO** 1028 West 120th St.

ly suited; for it makes it feasible to equip every car with its own drive. The multiple-unit train, where every car or every other car is self-impelled, exerts a much augmented tractive effort, so that it can reach full speed in a brief while after a stop. Where high-voltage, direct current is used, on the other hand, the locomotive is relied upon generally to do all of the pulling, and only its driving wheels are tractors. Accordingly, it takes longer to acquire or to resume maximum headway, and the condition of the tracks may interfere with this to such an extent as to impose the hauling of fewer cars.

On mountain sections, where high-voltage alternating-current distribution is provided, and the locomotives are driven by induction motors, the problem of handling heavy freight trains is radically modified for the better because of the uniform pace and good speed which these tractors can maintain both up and down grade. Further, this type of tractor places a minimum burden on the brake installation.

In densely settled areas, railway electrification has occasioned two reflex vexations. Alternating-current systems give rise to a phenomenon known as inductive interference, which is apt to upset the operation of nearby telegraph and telephone lines. This annoyance has been pretty effectually reduced by the proper bonding of the rails so that the return circuit is taken care of in a way to obviate the disturbance of neighboring systems of communication. Inductive interference, like a mischievous boy, promptly betrays its activities in an audible manner. Direct current, however, promotes the electrolysis of underground conduits, etc.; and the extent of its silent, insidious and destructive work is very frequently not detectable until collapse of the pipes, structure, etc., takes place. Then the damage may be of a very costly nature.

It is probable that no one system will be accepted to the exclusion of all others, but when a system is selected for a given railroad the decision should be made only after careful consideration not alone of the problems of that particular line but also of those of its neighbors—in this way achieving as complete a measure of unification as is economically possible.

## California's Seaweed Industry

(*Continued from page 445*)

The process of manufacture is ingenious and interesting in view of the fact that they designed all the machinery and equipment for a purpose entirely new. The whole takes seventy-two hours but operation necessarily is continuous. The leaves and stems of the algæ are used. One of the most clever conceptions in the factory is a battery of four "mortars" or bowls twenty-two inches in diameter and fourteen deep in a solid block of concrete, with corresponding quadruple wooden "pestles"—an adaptation on a modern mechanical scale of the primitive method of grinding. Into these mortars the raw material or dry weed is first placed and in a few minutes it is stamped into a fine mass. The object is to free it of the millions of tiny shells, bits of sand, alkaline deposits and other foreign matter. Then it goes through various tanks and vats, one containing a secret solution for bleaching and the others plain water for washing, after which it is run through a wringer and spread on racks to dry in the California sun. It looks like white moss.

Next it is boiled three to four hours, filtered, distributed in galvanized iron trays four feet long, two wide and three inches deep, and five hours later it comes out jelled, like a large sheet of rubber. In this form it comes to the sharp knives of another wonderful machine, which cuts it into pieces a foot long and two inches square, each intact but sliced lengthwise as are noodles. Having now undergone extreme heat a siege of the opposite character is provided, for it is placed on wooden trays and carried into a great refrigerating room and for ten hours kept at ten degrees below zero. The sticks come out solid ice. They are slowly melted, the water drained off, then put through a forcing machine which flattens each "noodle" into a thin, transparent sheet. Again the California sun is invoked to dry them. Finally they are tied in three-pound sheaves of silvery sheen, and thus they first go into the market.

The factory is also making a superior vegetable isinglass as an experiment and the owner believes he can approach in quality, at low cost, the Russian mineral isinglass now selling for $11.50 a pound. An adhesive plaster, photographic films and other products are included in his plans, which thus far have in nowise been disappointing. Potash, iodine and other by-products of the algæ will be conserved, appliances for that purpose being in course of installation.

## Edison's Views on Life and Death

(*Continued from page 446*)

lions upon millions of entities, and that our body and our mind represent the vote or the voice, whichever you wish to call it, of our entities.

"Now let's see why we must be composed of life entities. Supposing you take a finger print of your thumb, in the conventional manner of the police records. Then burn your thumb sufficiently to destroy the skin. Do you know that after the new skin has formed the finger print of your recovered thumb will be precisely the same as the first one? Yes, absolutely the same, even down to the last line and irregularity. I tried it to make sure. Here is a mystery which has remained unanswered until now.

"Of course, you say it is nature. But what is nature? That seems to me to be such an evasive reply. It means nothing. It is just a subterfuge—a convenient way of shutting off further questioning by merely giving an empty word for an answer. I have never been satisfied with that word 'nature.' Now my answer is that the skin didn't happen to grow that way again by accident. Someone had to plan the new growth and to supervise it to make certain that it would conform in every way with the old skin. You do not know just what that pattern is, and so your brain plays no part in the operation.

"Here is where our life entities come into action. I firmly believe that the life entities rebuild that thumb with consummate care, drawing upon their remarkable memory for all the details.

"Let us consider an analogy, for the sake of making my point more clear to you. Supposing that a man from Mars came to this earth, and his eyes were so much coarser than ours that the smallest thing he could see was the Brooklyn Bridge. He could not see us. Naturally, he might take Brooklyn Bridge for some natural growth, just as we consider grass, sand, minerals and other things as matters of natural development. Supposing that same man from Mars were to destroy the Brooklyn Bridge, and several years later he happened to find a new bridge in precisely the same place and of precisely the same design. Would it seem logical for that man to assume that the bridge simply grew again in the same manner and in the same place? Don't you suppose that the Martian would be compelled to assume that some intelligence and guided effort were behind the rebuilding of the structure he had destroyed?

"That is precisely the stand we should take regarding the life entities. Obviously, the entire matter is one of conjecture. Perhaps the entities in our bodies are ninety-five per cent workers and five per cent directors. At any rate, it is the ensemble of all these entities which gives us our physical form, mental properties, personality, and so on.

"The entities are life, I again repeat.

THE LEEDS COMPANY

They are steady workers. In our bodies these entities constantly rebuild our tissues to replace those which are constantly wearing out. They watch after the functions of the various organs, just as the engineers in a power house see that the machinery is kept in perfect order. Once conditions become unsatisfactory in the body, either through a fatal sickness, fatal accident or old age, the entities simply depart from the body and leave little more than an empty structure behind. Being indefatigable workers, they naturally seek something else to do. They either enter into the body of another man, or even start work on some other form of life. At any rate, there is a fixed number of these entities, and it is the same entities that have served over and over again for everything in this universe of ours, although the various combinations of entities have given us an erroneous impression of new life and still new life for each generation.

"The entities live forever. You cannot destroy them, just the same as you cannot destroy matter. You can change the form of matter; but of gold, iron, sulfur, oxygen and so on, there was the same quantity in existence in the beginning of this world as there is today. We are simply working the same supply over and over again. True, we change the combinations of these elements, but we have not changed the relative quantities of each of the elements with which we started. So with the life entities, we cannot destroy them. They are being used over and over again, in different forms, to be sure, but they are always the same entities.

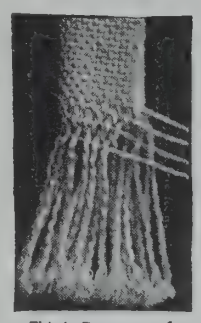
"The entities are so diversified in their capabilities that it is difficult to identify their handiwork in all instances. Thus today the scientists admit the difficulty of drawing a line of demarcation indicating where life ends and inanimate things begin. It may be that life entities even extend their work to minerals and chemicals. For what is it that causes certain solutions to form crystals of a very definite and intricate pattern? Nature! But what is nature? Is it not fair to even suspect that life entities may be at work building those crystals? They don't simply happen. Something must cause certain solutions always to form certain kinds of crystals.

"Now we come to the matter of personality. The reason why you are Lescarboura and I am Edison is because we have different swarms or groups or whatever you wish to call them, of entities. After eighty-two remarkable surgical operations the medical world has conclusively proved that the seat of our personality is in that part of the brain known as the fold of Broca. Now it is reasonable to suppose that the directing entities are located in that part of our bodies. These entities, as a closely-knit ensemble, give us our mental impressions and our personality.

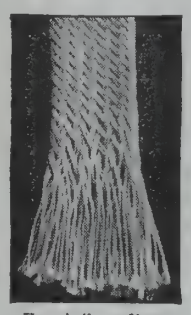
"I have already said that what we call death is simply the departure of the entities from our body. The whole question to my way of thinking, is what happens to the master entities—those located in the fold of Broca. It is fair to assume that the other entities, those which have been doing purely routine work in our body, disband and go off in various directions, seeking new work to do. But how about those which have been directing things in our body—those which are Lescarboura, Edison, Meadowcroft and so on? Do they remain together as an ensemble or do they also break up and go about the universe seeking new tasks as individuals and not as a collective body? If they break up and set out as individual entities, then I very much fear that our personality does not survive. While the life entities live forever, thus giving us the eternal life which many of us hope for, this means little to you and me if, when we come to that stage known as death, our personality simply breaks up into separate units which soon combine with others to form new structures.

"I do hope that our personality survives.

# Duracord on portable coal conveyors



*This is Duracord. Thick, heavy strands, woven like a piece of fire hose, not braided. Picture shows outside covering only with impregnating compound removed.*



*Here is the ordinary braided cable covering. Note the open and porous construction, easily cut, stretched or unraveled. Compare it with the illustration of Duracord above.*

PICTURE the wear it gets. Dragged around the yard, run over by heavy wagons, walked on, buried under falling coal—Duracord defies it all.

This sturdy portable electric cord is made for just such service. It has a big thick *woven* fabric covering that accepts its full responsibility and never lays down on the job. It outwears ordinary cord many times.

**DURACORD**
TRADE MARK REGISTERED

In addition to portable conveyors, Duracord is used on magnetic cranes, mining machinery, locomotive headlights, cement mixing machines, welders, portable electric tools, extension lamps—wherever the ability to stand hard knocks is an asset.

Duracord is made in all sizes of portable electric cord and the larger sizes of single and duplex cable. Ask your electrical jobber or let us send you samples of Duracord and ordinary cord for you to test and compare yourself.

Brockton, Mass.

# RELATIVITY

## The Special and the General Theory

By Professor Albert Einstein, Ph.D. LL.D.

Translated by Professor Robert W. Lawson, M.Sc.

THE authorized English translation of Einstein's own book explaining his theories to the general public is now available. Dr. Einstein has scored a conspicuous success in this volume, steering a skillful course between the twin dangers of too much mathematics and too little explanation. Also, he makes clearer than has yet been made just wherein lies the dividing line between his special theory and his general theory, and just where the two join. In literary style as well as in clarity of exposition this book bids fair to take rank as a classic; and in any event, it is by far the most satisfactory treatment of the subject to be had at the presen date in English.

If it does, then my apparatus ought to be of some use. That is why I am now at work on the most sensitive apparatus I have ever undertaken to build, and I await the results with the keenest interest."

## Getting a Line on Concrete Pipe

(*Continued from page 449*)

type of the finished product can be compared with other joints of pipe made of specially prepared mixtures, the comparison reflecting the character of materials, proportions, water content and other ingredients.

Permeability tests are conducted upon the completion of the tensile-strength investigation, the same specimens being used. A concrete block, one side of which conforms to the inside surface of the specimen, constitutes the testing apparatus. It is held against the surface by two clamps. Water is furnished through a one-fourth-inch iron pipe running through the tester to the surface to be tested. Escape of water is barred by an inflated gasket seated in a groove around the edge of the tester. Fifty pounds of water pressure is applied for one-half hour. The quantity of sweat or seepage is noted at 5-minute intervals. Specimens are air-cured 29 hours and water-cured 3 weeks. Absorption tests are made on the same specimens. These are dried out in an electric oven to constant weight and then immersed in water. Weights are taken at one-half hour, 4 hours and 48 hours. The percentage of absorption is based on dry weight.

Definite results, although not comprehensive because of the incompleteness of the investigation, are available from the experiments. An outstanding conclusion is that proper grading of select material is the most essential factor in the manufacture of an excellent quality of concrete pipe. The porosity of a pipe is influenced largely by the grading of the material. Rock dust up to 10 per cent and clay free from organic matter up to 5 per cent have proven their efficacy in preventing seepage without decreasing the strength of the pipe.

Laboratory tests show that a substantially large variation in water content does not materially influence the strength of the pipe, conditional upon the mixture being heavily tamped. Under light tamping, pipe made of a so-termed "dry mixture" is much weaker and seeps freely. A first-rate quality of broken rock of uniform toughness insures the strongest pipe. This may be attributable to the difficulty of finding gravel free from soft or disintegrated particles in California. The breaking strength of concrete pipe under water pressures varies widely, the variation being due to the manner of testing. If a pipe is thoroughly saturated several days before the test is made a good quality of pipe will test as high as when dry, while a poor quality shows a decrease in strength of from 20 to 60 per cent.

That concrete expands and contracts when influenced by changes in temperature, is knowledge of general acceptance. However, the information that a concrete pipe expands when changed from a dry to a wet condition and contracts to a like extent when the conditions are reversed is not such common knowledge. A concrete pipe, when subjected to water pressure for some time, if permitted to dry, may contract as much as it would under a drop of temperature of 100 degrees Fahrenheit. Excessive internal stresses in concrete pipe, not infrequently resulting in ruptures, are created by having the lower part of a pipe line wet if not saturated and the upper part dry. Seepage through the shell of a pipe under water pressure will appear under low pressures nearly as rapidly as under high pressures. If water is going to percolate through a pipe, a pressure of 5 pounds to the square inch will indicate with reliable accuracy the quantity of water likely to pass through the shell.

## Hardening Steel in Gas-Fired Furnaces

(*Continued from page 450*)

of quenching is not quite so rapid, or as severe as water or brine, yet quick enough to give the proper hardness to most all work.

It is important to keep all quenching baths cool, and replenished from time to time with a fresh supply of the liquid. Where water is used it is best to keep up a fresh supply continuously. Oil baths are cooled either by a series of cold water pipes around the tank, an agitation of the oil by compressed air, or a circulation of the oil. The last-named method is perhaps the best as it not only causes a cooling o fthe oil but also a constant changing of the bath and takes the heated oil away from the metal after it gives up its heat to the oil.

Quenching should be done rapidly but uniformly. Tongs for holding the work should have as small grip as possible. Long pieces of steel, including drills and reamers should be quenched with their axis vertical. Where this is impossible such as in very long round rods, they should be made to roll into the quenching bath with their long axis horizontal, but they should enter the bath very quickly. Round cutting tools should be immersed with their axis horizontal. Small tools or pieces should be kept in motion when placed in the cooling bath.

Warping occurs frequently in hardening steel pieces and may be attributed to one of two causes—uneven heating or quenching too long. Some pieces should be left in only long enough to harden extreme edges. Again it is often necessary to immerse the piece at an angle in order to overcome this difficulty. Therefore, it will be necessary to give considerable thought to the shape and design of the tool, in order to obtain the best results.

## The Heavens in November, 1920

(*Continued from page 452*)

Jupiter is a morning star, rising at 1 A. M. in the middle of the month. Saturn is about seven degrees farther east, and rises half an hour later. The two planets are on the borders of Leo and Virgo, and afford a fine spectacle in the morning sky. Uranus is in Aquarius, observable in the evening, and Neptune is almost opposite in the sky, and visible before daybreak.

The moon is in her last quarter at 3 A. M. on the 3rd, new at 11 A. M. on the 10th, in her first quarter at 3 P. M. on the 18th, and full at 9 P. M. on the 25th. She is nearest the earth on the 27th, and farthest off on the 15th. During the month she passes near Neptune on the 3rd, Jupiter on the 5th, Saturn on the 6th, Mercury on the 11th, Venus on the 13th, Mars on the 15th, Uranus on the 18th, and Neptune again on the 30th.

On the morning of the 10th there occurs a partial eclipse of the sun, which is visible throughout the northern and eastern portions of the United States, and as far west as Kansas. The eclipse begins about 9 A. M. eastern time and lasts more than two hours for observers in New England and the Middle States, about one-third of the sun's diameter being obscured on the northern side. The magnitude of the eclipse will be smaller, and the duration shorter for observers farther south and west, till it fades away to nothing in Alabama and Arkansas.

## Do Moths Use "Wireless"?

IT has for long been known that certain species of moths are able to communicate with one another even though separated by a considerable distance. This fact is to be noticed very plainly during the pairing season. A female of the Vapourer Moth (Orayia) may be enclosed in a wooden pill box. She will then attract males from all directions, and these will come from a distance of a mile or two.

THE MOST SCIENTIFICALLY BUILT WATCH IN THE WORLD

## The Waltham Scientific and Exclusive Process of Hardening and Tempering the Hair Spring in Form

THE Hair Spring is to the balance wheel of a watch what gravity is to the pendulum of a clock.

The Hair Spring is so extremely important in its mechanical functions that we affirm — a watch is only as good as its hair spring.

Therefore, the Hair Spring that most closely approximates perfection in the watch you buy gives you more value for your money as a time-keeper and as an appreciated investment.

*The Waltham Hair Spring is the only Breguet Hair Spring in the world that is hardened and tempered in form.*

In other words, the end of the unscientific hair spring is twisted into the Breguet shape *after* the spring is hardened and tempered.

Therefore, if this unscientific hair spring happened to be of *fine* steel temper, it would have to function under undue stresses.

What does this imply? That, sooner or later, the resiliency of such a spring *must* deteriorate, making the watch an erratic time-piece.

The genius of Waltham overcame this unknown factor of irregularity in the Hair Spring by inventing and patenting a process whereby the whole hair spring was shaped to its ultimate use *and kept in that perfect shape* while being hardened and tempered.

The over-coil called Breguet (after the name of its inventor) was a great invention of years ago, but it affected only the outer half of the spring. And, because of the Waltham scientific method of hardening and tempering in form, it became possible for Waltham to perfect and add an inner terminal bend which gives equal action to both ends of the spring.

*This is a vital and exclusive Waltham invention.*

It gives to a Waltham Watch a greater dependability and a closer precision. It has made the Waltham Watch the most sought after watch in the world. It gives to the buyer of a Waltham Watch a confidence that herein is the art of watchmaking at its highest development.

Last, but not least — the Waltham Scientific Hair Spring hardened and tempered in form is an *American invention,* exclusively Waltham —

An unanswerable argument why your watch selection should be a Waltham.

**Waltham 7½ Ligne**

The movement is actually smaller than a dime in diameter

$250 to $1,500 or more depending upon the case

# You never know what a car can do until you get a PACKARD

AFTER all, the chief difference between the Packard and some other car is very easily stated.

It is the difference between giving the owner *everything he can make use of*—or building down to the least he can ask of his car.

If there were any compromise anywhere in the Packard Car; any attempt to build down to a competitive price basis; any feeling in the Packard organization that the American public can be influenced by pose or "side" or talk of "What they do in Europe"—the Packard could not be the *practical car* it is.

There are a number of cars with high power ratings.

Yet you see the Packard running all around them.

It is the same way on the hills as on the level road; and the first car to shoot out of the traffic jam is a Packard.

You will hunt far before you find a car of equal size that does its work on such a slight expenditure for gas and tires.

The thing that sets the Packard apart is its *forethought for all the use* a man can make of his car.

PACKARD MOTOR CAR COMPANY, *Detroit*

## TWIN SIX

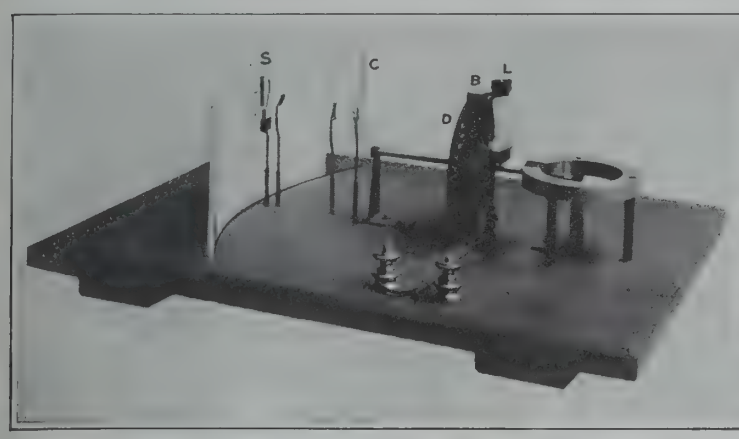

Fig. 1—Skeleton apparatus showing the principle of the "black-sounding" optophone

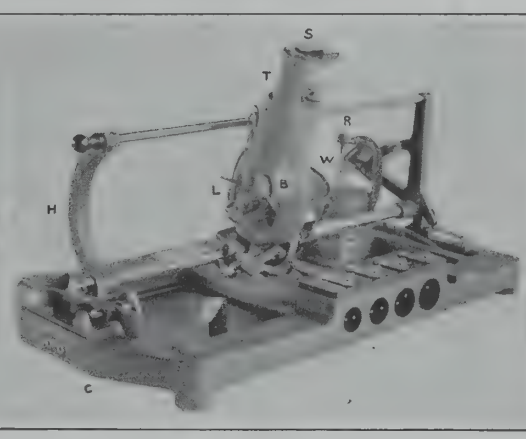

Fig. 2—The optophone with book rest removed, showing the "tracer" mechanism

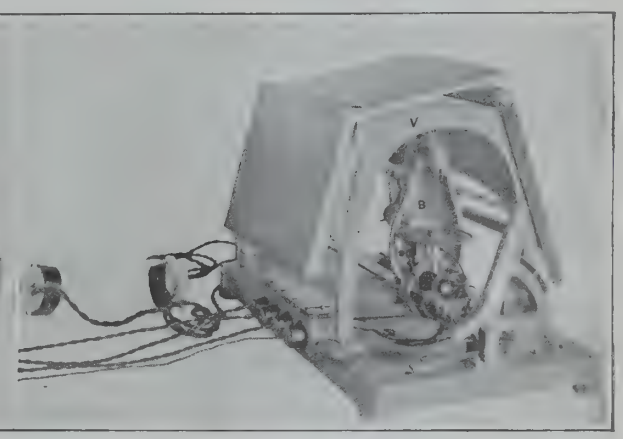

Fig. 3—The optophone complete with conventional book in place ready for reading

**Simple and standard forms of optophone which enable the blind man, after some practice, to read type matter by means of sound**

## The Type-Reading Optophone

### An Instrument Which Enables the Blind To Read Ordinary Type

IT would be difficult to conceive of a more remarkable electrical device than the type-reading optophone, which enables the blind to read ordinary type. This device, be it understood, is not altogether new as far as its basic principles are concerned. As far back as August 3rd, 1912, the SCIENTIFIC AMERICAN SUPPLEMENT carried a description of the first optophone which in its earliest form was an instrument for converting light into sound in such a manner that the blind were enabled to see by ear, so to speak.

The optophone was the invention of Dr. E. E. Fournier d'Albe of Birmingham University. Dr. d'Albe later developed a type-reading instrument by which the blind could read large print. Recently the instrument has been greatly improved in coöperation with Messrs. Barr and Stroud of Glasgow, the well-known instrument makers. In its present form it can be adjusted for any ordinary type, but it is well to direct attention to the fact that the blind person making use of the optophone must have a very fine musical ear in order to grasp the tone combinations emitted by the instrument and translate them into reading matter.

The general principle of the apparatus is shown in Fig. 1, wherein a siren disk, *D*, is run at about 30 revolutions a second by means of the small magneto-electric motor shown. It contains five circles of square perforations, the innermost circle having 24 perforations, the outermost 42, the other circles being intermediate and corresponding to the relative frequencies of certain notes of the diatonic scale. A line of light in a radial direction is provided by the straight-filament lamp *L*, and the image of the filament of this lamp is thrown upon the print by a system of three lenses on the other side of the selenium tablet *S*. The axis of the concavo-convex lens *C* is slightly tilted out of the axis of the other lenses for a purpose which is specified below. The general result of the optical system is to give a line of luminous dots on the print, each dot having a different musical frequency. The light constituting these dots is diffusely reflected back on to the selenium, which is put in circuit with a battery and a high-resistance telephone receiver. Those dots which fall on white paper produce a note of their own musical frequency in the telephone, while those which fall on black are extinguished, so to speak. We thus get what may be called a "white sounding" optophone, in which the black letters are read by the notes omitted from the scale rather than by the notes which remain sounding. All the reading demonstrations hitherto undertaken have been given with a "white-sounding" optophone, with the most satisfying results.

A modification of this principle, we learn from the SCIENTIFIC AMERICAN MONTHLY [successor to the SCIENTIFIC AMERICAN SUPPLEMENT] for October, has been introduced by Messrs. Barr and Stroud in consultation with Dr. d'Albe. This is the provision of a second selenium preparation in the form of a cylindrical rod, the top of which can be seen at *B*. This rod receives the light reflected by the concave surface of the lens *C*, which produces a real image of the line of dots on a generator of the cylindrical rod, and by turning this rod about its axis the image can be made more or less effective as desired. By balancing the effect on *B* against the effect on *S*, when white paper alone is exposed, a silence can be produced in the telephone, and the effect of the passage of a black letter is to make a sound which varies in accordance with the formation of the letter. This is the principle of what may be called a "black-sounding" optophone, and although its advantage over the "white-sounding" type has yet to be proved, there is little doubt that the learning of the alphabet sounded on the new principle will be easier.

The present construction adopted by Messrs. Barr and Stroud is shown in Fig. 2. Here the disk, lamp, lenses, and selenium, as well as the motor, are all mounted in the swinging "tracer," which can be brought over to the right by means of the reading-handle *H*. It then returns to the left with a slow, silent and steady motion regulated by the worm gearing *W*, which drives a small paddle inserted in a viscous liquid. This paddle can be inserted more or less deeply into the liquid by the regulating nut *R*, and such is the range of adjustment possible that a line can be read in anything from five seconds to five minutes, according to the proficiency of the reader. When the line is read, the next line is brought into focus by the change-bar *C*, which works a friction grip inside the bar on which the "tracer" is pivoted, and can be adjusted for any desired line space by means of the screw attached to the change bar. A lever attached to the "tracer" enables the operator to reverse this motion or to release the whole "tracer" from the friction gear, so that it may be quickly brought to the top of the page.

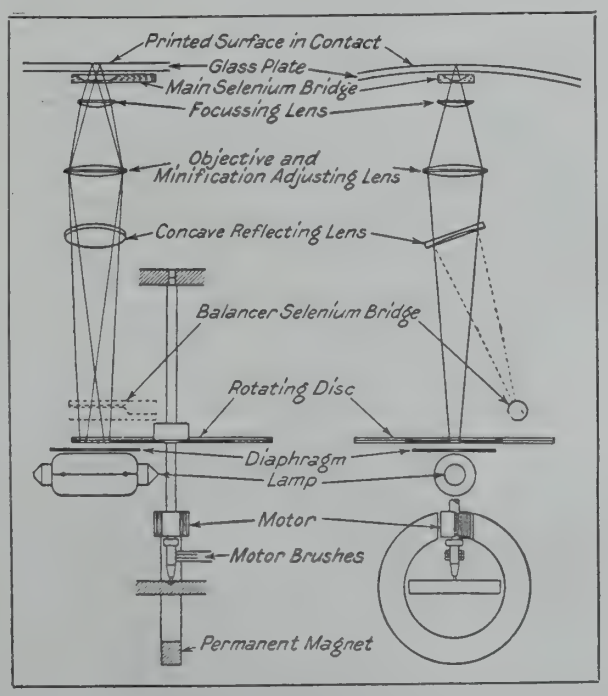

**Diagram of the arrangement of the optophone as seen from two sides**

The straight-filament lamp is inserted at *L*, where it is held by a spring clip, and whence it can easily be removed for renewal even by a blind operator. The balancer is inserted at *B*, and can be adjusted for silence by means of the small handle shown.

Fig. 3 shows the apparatus from the top page end and with telephone and flexible connections attached, as well as the book-rest *V* holding a book. The adapters of the flexible connections are all of different sizes and fit into different-sized holes in such a manner that they cannot be wrongly inserted.

The operator of the optophone reads by the tones and combinations of tones emitted by the telephone receiver. The numbers of perforations in the siren disk are in proportion to the notes G, C′, D′, E′, G′, (sol, do, re, me, sol) of the musical scale. The spot of light corresponding to low G falls on the lowest point of such letters as j, p, y, etc., the high G′ falling on the tops of capitals and high letters. The three intermediate spots cover the body of the lower case letters. With a "black-sounding" optophone the letter *V* is represented by the motif (high) sol, me, re, do, re, me, (high) sol.

In practice it is found that, with the new apparatus, the various adjustments for size of type, length of line, and line interval are quite easily made by blind persons, and that the instrument, with all its delicate adjustments, can remain in use for a long time without anything getting out of order. As for speed of reading, we are told that Miss Mary Maeson, the blind girl who has been giving demonstrations with the optophone for some time, now reads habitually at a speed of about 25 words a minute with a "white-sounding" optophone. But again we repeat, a so-called musical ear is a very necessary qualification.

## Our Surplus, Our Ships, and Europe's Need

THANKS to our enormous industrial development during and even since the war, thanks also and even more to weather conditions extremely favorable to agriculture, the United States finds itself with a great surplus of products on its hands. Also, because of our enormous shipbuilding activities during the war and since, we find ourselves possessed of the second greatest merchant fleet in the world, with probably 70 per cent of it consisting of absolutely new shipping and most of it made up of cargo-carrying vessels.

On the other hand, if we turn from the thought of our own superabundance and let our gaze rest upon Europe, we find there a scarcity so great that the peoples of the old world, or at least of the western half of it, are looking with hungry eyes upon our unused and unusable superabundance. At present market values we have surplusses, available for export, of $800,000,000 in cotton, $600,000,000 in wheat, $250,000,000 in packing-house products, $750,000,000 in semi-manufactured raw materials and finished manufactured products of various kinds—all this according to E. M. Hurley.

There is no lack of ships. Anyone who has had occasion to traverse any of the great harbors of the Atlantic seaboard must have wondered why in the world such quantities of cargo ships flying the American flag are floating high and empty on the mooring grounds of these harbors. It certainly does seem pathetic or monstrous or wasteful or ridiculous, according to the point of view of the speaker, that so much suffering, unrest and threat to the social and economic structure should be allowed to persist, when the means to relieve it in the way of surplus products and surplus ships are right at hand.

If that overworked "Visitor from Mars" were to ask the why and wherefore of these amazing conditions, he would be told, as Mr. Hurley recently told the diners at a banquet of the National Marine League, that "while the countries of Europe are in the market for the major portion of our surplus, our marketers of wheat, cotton and other products still ask for payment in gold at our seaports before goods are shipped." In answer to his inevitable question as to why they do not pay in gold, we should have to explain to him that most of it is already in this country.

To the student of economics the explanation is perfectly clear. These suffering countries cannot pay us in gold for they have it not. It is out of the question for them further to inflate their currency by creating huge indebtedness, for they are already overloaded. The problem is not one to be solved by the assistance of the United States Treasury, for already we have loaned over ten billion dollars to Europe. It is the belief of Mr. Hurley and of an increasing number of our leading business men that the problem should be solved strictly on a commercial basis. With these enormous excess products to sell and with our natural overseas customers restricted in their purchasing power, we should coöperate to place them in a position to make their needed purchases. It should be possible for the marketers of these divers products themselves to work out coöperatively a system of credits; and it is suggested that the creation of a commercial bond issue of from one hundred million to one hundred and fifty million dollars would furnish a sufficient fund during the period of the marketing of these products. What is needed and needed at once is a relatively limited creation of additional private credit without invasion of government credit.

As to the security, the marketers of the various products would receive in return an obligation from the purchaser, definite as to amount and interest and time of payment. These would constitute the security. They would have the guarantee of the purchaser's particular Government, which, Mr. Hurley assures us, nearly all of the European Governments are willing to grant. It is possible also that the guarantee of the marketers in this country would be added. We do not doubt that this relatively small bond issue secured in the manner suggested would be quickly absorbed here. The benefit to Europe would be immediate and incalculable.

## Joys and Sorrows of the Einstein Editor

EVERYTHING has its lighter side. Even the Einstein Editor, on whom devolves the function of opening and recording the essays received in the contest and preparing the tentative abstracts of them for the use of the judges, reports that his cloud has a silver lining. We consider this the height of optimism; for at the hour of going to press there are 151 essays in, with five days still to run.

However, the unfortunate member of the staff most directly involved assures us that the bright spots are there. For one thing, he regrets the day when he rashly required the contestants to send their inner envelopes sealed. In Europe this means legally sealed and stamped with a splash of wax—or several splashes. It is, on this side, rather a novel experience to receive a bulky envelope bearing five ponderous red or black smears—one at the crossing of the flap in the middle and one off toward each corner; and on opening this, to discover in it two smaller envelopes, each similarly decked out. There has been enough wax used in this contest to float a dreadnought.

Another amusing item is the envelopes. Purely on the basis of mathematics, if 151 gentlemen are to select two small envelopes and a larger one to hold them, it would seem that some two of these 453 containers would necessarily be of the same size and shape. The Einstein Editor finds that performance gives the lie to theory; and he contemplates a dissertation in which the foundations of the theory of probability will be revised. It is impossible that the world contains so many different styles of envelope—impossible, but true.

A curious feature is that several contestants have selected subjects of their own—"Mastering Success," "Leagues of Nations in History," "The Situation of a Government Clerk in the Madras Presidency, India," etc. We are puzzled to know whether local papers have announced the contest without troubling to announce that the subject was prescribed; or whether these worthies have tried to display a Machiavellian cunning in writing on a subject of which the judges shall not be wearied.

Discounting the few trivial essays inevitable in such a contest, the general level of competition is gratifyingly high. It is interesting to note that German and French and Dutch authors show on the whole rather good command of the English language. One German essay, in particular, on being examined by our two editors who display greatest literary talent, provoked the admission that, with the same ideas to express, neither of these gentlemen would dare hope to clothe them in more elegant or more precise English. By way of contrast, there comes another effort which bears indisputable evidence of having been written first in German, and then, with the aid of a dictionary and a colossal ignorance of the English language, lifted over, word by word, into English. The author confides that he hopes to win the prize, but that failing this he has at least "learned some English." Just how much, appears from the following excerpts:

"Some 400 jears ago the earth was a side-ways unboundet mass, above the heaven and under the hell. By degrees but heavy one accustomed thereon, that under us also men live and thereto with the feet to above and they stand however fast on the earthground, when they with the finger to above show, so is that the same direction, as we under name. . . . So will go also a time, that all thereon accustom, that after Einstein we not a absolute and only a relative time have. . . . Think we us the world-room like a absolute reposing empty reservoir. . . . Einstein remove this hardiness. . . . Think we us a planet go tight to the earth over, our clocks have equal going time. . . . When now the time-measurings of two world-bodys are differently and therefore a world-body not can direct his clocks after they of the other world-bodys, but we should be able, the inhabitants of the planet to convince from the contemporary existence of our clocks in two differently points on the earth. . . . But uniform moving curvations are not on the pathway of the world-bodys in the whole world-room according of the gravitation or far-effect, where by the objects move with changed hasting swiftness in crooked curve-lineal pathway. . . . The lines of a system run liking so by each others, that they opposite not cut through and all the points of the world-room befal."

Some knowledge of German is of course necessary to a full appreciation of this gem. Those lacking such knowledge will get a clue to the author's general style by comparing his first two sentences above with our editorial of Dec. 20 last, "The Nature of Things," in which the Einstein Editor set forth the same general ideas. Are we to assume that this is even his source? If so, we are flattered indeed!

## The Stability of Ships

IT would be instructive to know what proportion of ships that founder do so because they have insufficient stability. Everyone that takes an interest in matters pertaining to the sea must have noticed how frequently the efforts to save an injured ship are cut short by her capsizing. Many people must have noticed, during the war, that a majority of the warships that were heavily punished by the torpedo or by gun fire turned turtle before they sank, and the history of the merchant marine teaches the same lesson. It is not sufficient merely to protect the flotation of a ship; her stability also must be assured.

Naturally, the matter of stability becomes of more importance and requires greater watchfulness in proportion as the vessel is in a light condition and standing high out of the water. The naval designer makes careful calculations, and before the ship passes out of his hands, determines what ballast she should take aboard to compensate for the absence of cargo, and these data are furnished with the ship. Naturally, because of the great diversity in the model of ships and in the service to which they are put, the margin of stability will vary greatly also, and in some vessels it is necessary to exercise particular watchfulness.

A striking example of this is found in the capsizing last June of the U. S. Navy Eagle Boat "Number 25" during a violent squall in the Delaware River. From the findings of the Naval Court of Inquiry, we learn that this boat, being in an unusually light condition of load, had such a comparatively small range of stability as to make her an unsafe sea boat; that this condition was due mainly to the absence of her allowance of ammunition and to the fact that she had exhausted her supplies of fuel oil, water and stores. There was no stability data regarding the operation of the vessel on board the ship.

Rear Admiral Taylor, whose Bureau was responsible for the design of the ships, shows that responsibility for the disaster was not to be laid at the door of the Bureau of Construction and Repair. He tells us that when the first Eagles were completed and after an investigation of their stability, his Bureau issued a memorandum calling attention to the desirability of taking water ballast aboard when at sea in light condition. The data was furnished to the Eagle vessels then in commission, and instructions were issued to the superintending constructor at the building yard to see that every vessel, when completed, had a copy of the stability data. This order was not carried out.

Any repetition of such a disaster is to be prevented by placing fixed ballast aboard all Eagle boats, and this will give them such stability that there need be no concern about water ballast in any probable seagoing condition.

## Electricity

**A Blazing Fire with Electricity** instead of coal is the latest electrical development in England. It is known as the electric fire and can be fitted into any existing grate. This electric fire has the same blazing appearance at any adjustment, ranging from 200 watts to three kilowatts consumption. There being no combustion, no flues or chimneys are necessary and the fire is particularly essential in ships. Both the "Olympic" and the "Aquitania" are fitted with these fires.

**Convertible Caps.**—The electrical industry has a tendency toward standardization of fittings and accessories, just as in any other progressive industry. Just now there is a move on foot to make all caps for attachment plugs and wall receptacles convertible so that the blades can be made to fit any arrangement of slots. There are parallel slots, tanden or in-line slots, angle or T slots, and double T slots; but the new convertible caps can be adjusted for any arrangement of slots.

**Radio Compass for Directing Airplanes to Ship.**—Guided entirely by radio compass signals, a Naval seaplane "F-5-L" left Norfolk and flew 95 miles on a straight line to pick up the battleship "Ohio" at sea, with no knowledge at the time of taking the air of the vessel's location, according to *Wireless Age*. The seaplane then navigated its return to Norfolk entirely by radio compass. Navy Department officials to whom the flight was reported said it was the first time radio compass apparatus had been used to direct aircraft to a ship.

**Pictures via Radio.**—"Very interesting and very important" is the way Marconi recently expressed himself regarding the transmission of photographs by radio. It appears that several systems of this kind are being worked out at present, one of which known as the Belin system is described elsewhere in this issue. "I have not followed the experiments, but I know it can be done," continued Marconi. "Pictures were sent over telegraph wires several years ago, and what can be done by wire can be done by wireless. It will be of great interest to watch the progress made. The two chief uses to which the discovery can be put are the quick transmission of photographs for newspaper and police purposes."

**Radio Telephones for the Foresters.**—The British Columbia forestry branch has recently closed a contract with the Marconi Wireless Company of Canada for the installation of four land stations and five launch equipments, for use in forestry and fire-protection work. One station, at the forestry office in the courthouse, Vancouver, is already installed, and the first installation on one of the small gasoline boats has been placed. Successful tests have been carried out between these two stations at distances varying up to 75 miles. On account of the rugged character of the coast country this distance is the limit of the radius to be attempted for the present, although the extreme radius of the wireless telephone is stated to be 300 miles over flat land or over water.

**Telephoning Over High Voltage Lines.**—An American concern has recently developed an unusual system of telephony which can be used for communication over the usual high-tension lines. Thus there is provided a reliable and safe telephone system which best solves the power companies' communication problem and can be obtained with a telephone line mounted on the same poles as the transmission lines, without transformers or drainage coils; telephone sets in all stations which are safe to operate during serious line troubles; portable apparatus easily carried by any patrolman or line gang, which can safely be connected to the telephone line at any point. Any station can call other stations. Patrolmen or line gangs can call into a station from any point along the line. A station can call any patrolman or line gang near the telephone line. The apparatus, which is obviously different from existing telephones, may be described in a future issue.

**Recent Tendencies in Cable Manufacture.**—From a recent issue of the London *Electrician* we learn that the British have led in the development of satisfactory cables for underground transmission, for the reason that underground transmission is so commonly adopted in England. It is said that impregnated paper has proved its value by being used to an enormous extent for all pressures and conditions, and that it is the only really reliable and satisfactory dielectric for extra high pressures. The only serious competitor is vulcanized bitumen, which has lately emerged into an article of general manufacture and use. Its rise is mainly due to the extension of electricity in the mining industry. Being neutral to the peculiar moist conditions in mines, independent of a heavy sheath, semi-flexible, and not requiring the skilled care of a hydroscopic dielectric, it has found acceptance among colliery managers. It is also held that the steady rise in working pressures from 3,000 volts to 30,000 volts has not produced any drastic change in cable materials.

## Astronomy
